KENWOOD TS-700A 2 METER TRANSCEIVER

By Fred Goldstein WA1WDS

Two meters has come a long way since the days of Twoers and Gooney Boxes. While FM is the most popular mode of activity, there's plenty of SSB and even CW on the band nowadays, particularly in the OSCAR segments.

It takes a pretty good radio to get full enjoyment out of the band, and the Kenwood TS-700A is more than just a pretty good radio. Full band coverage is provided in four segments, with VFO or crystal control. You get FM, CW, upper and lower sideband, even AM. Power output is conservatively rated at ten Watts. The built-in power supplies are for both 117 V ac and 12 V dc.

The design is quite modern and innovative. On SSB, the unit is single conversion, with a crystal lattice filter at the 10.7 MHz i-f. The crystal bandswitched oscillator is premixed with the 8 MHz VFO and extensive bandpass filtering provides very low spurious response and emission. For FM, a second i-f at 455 kHz provides additional selectivity and improved audio recovery.

Kenwood didn't spare expense when it came to putting in the filters. There's a 20 kHz crystal filter coming out of the first mixer into the noise blanker. The blanker compares the noise across that bandpass with the noise within the SSB bandpass, and the blanking action is amazingly good. There's probably at least 30 dB of blanking available, if the noise gets bad enough. At my QTH, it never was strong enough to get through the blanker, and my other FM rig is driven batty by passing cars and trucks. When the SSB is less prone to noise than an FM receiver, that's a good blanker!

Coming out of the blanker, the SSB is cleanly tailored to its bandpass and sent to the i-f amplifiers and detector. For FM, the signal is converted down to 455 kHz, where two ceramic filters result in phenomenal selectivity. Splinter channels are no problem whatsoever with the TS-700A. I could listen to 146.625 and hear nothing but an occasional splattering voice peak even though the repeaters on .61 and .64 are very strong here. This is even better than the results I had with other expensive synthesized rigs. If everyone had a radio this sharp, the 2 meter band wouldn't seem half as crowded as it does now.

Not that the sensitivity isn't good. I was hearing signals on the TS-700A that most other radios couldn't tell were there. The VFO helps, too, since there are no "secret" frequencies with one. For repeater use, the transmitter is 600 kHz low in the 146 portion, 600 kHz high in the 147 portion. Putting the repeater switch on "reverse" inverts the operation, which is necessary for California plan inverted splits.

The VFO calibration is good within 1 kHz across the band, and the center

tuning position on the meter helps put you right on frequency. There's a 100 kHz crystal calibrator just in case you like to be exact. The unique "S-meter" circuit helps tuning on FM, too. The meter is left on the SSB i-f strip, so the repeater carrier has to be within the SSB bandpass to get a reading. The meter doesn't pin on strong signals like on most FM rigs, so you can accurately give a signal strength report or turn the beam using the meter as a guide.

If tuning a VFO while mobile seems a bit too difficult, there is room for eleven crystals. Since each crystal is at the VFO equivalent frequency, there's no need to use separate receive and transmit crystals. If your area has a repeater with 146.46 in and 147.06 out, a crystal for 1.006 MHz above the bottom of the 146 segment will put you there. Tuning in 147.06 would normally result in a 147.66 repeater input, so you need the crystal. If your area conforms to the usual American bandplan, you don't need any crystals.

There are other good features to the TS-700A. There are several varactor-tuned stages, including the front end, that optimize performance as you change band segments. The final has a tuning control, and there's even driver peaking, so you don't have to worry about losing sensitivity at one end of the band or the other. VOX is available as an accessory. If you really want some fun on two meters, the TS-700A will really deliver.

SOCIAL EVENTS

COLUMBUS GA
MAY 8-9

The Columbus Amateur Radio Club (Georgia) is holding its annual Hamfest on Saturday and Sunday, May 8 and 9th. The hamfest will be at the Fine Arts Building, Columbus Municipal Fairgrounds, Columbus, Georgia. For further information contact Dennis Hand, Jr. K4ICR, Route 1, Box 172A, Cataula GA 31804.

AMBOY IL
APRIL 25

The Rock River Hamfest will be held April 25, 1976, Amboy, Illinois Lee Co. 4-H Center Jct. 30 & 52. Same place as last year. $1 advance, gate $2, write Carl Karlson W9ECF, PO Box 99, Nachusa, Illinois 61057. Rain or shine – indoor or out, camping, large swap shop, food, and many prizes. Short trip west of Chicago. Talk-in 146.94.

SULLIVAN IL
APRIL 25

The Moultrie Amateur Radio Klub announces its 15th Annual Hamfest at the American Legion Pavilion in Wyman Park, Sullivan, Illinois on the 25th of April, 1976. Rain or shine, same place as always.

CADILLAC MI
MAY 1

The Wexaukee Amateur Radio Association announces their 16th Annual Swap-Shop and Eyeball that will be held May 1st in the National Guard Armory in Cadillac, Michigan, starting at 9 am. This Swap-Shop is open to all radio amateurs, citizens banders, and anyone interested in radio communications. Lunches will be available at noon and there is lots of free parking. Tickets available at the door.

MEADVILLE PA
MAY 1

The Northwestern Pennsylvania Swapfest will be held May 1, 1976 at the Crawford County Fairgrounds, Meadville PA. Free admission. $1 to display. Flea market begins at 10 am. Hourly door prizes and refreshments. Commercial displays welcome. Indoors if rain. Talk-in 146.04/64 and 146.52 MHz. Details: Crawford Amateur Radio Society, Box 653, Meadville PA 16335.

BIRMINGHAM AL
MAY 1-2

The Annual Birminghamfest Amateur Radio Convention will be held May 1 and 2 at the Alabama State Fairgrounds in Birmingham. Headquarters hotel: Sheraton downtown (on I-65). Features: giant two-day indoor/outdoor swap circle, manufacturers' exhibits, forums, displays, family activities, prizes galore, free Saturday night party, much more! Talk-in: 34/94 (WR4ADD), 3965 kHz. Information: B.A.R.C., PO Box 603, Birmingham, Alabama 35201. Sheraton reservations: 1-800-325-3535.

KANSAS CITY MO
MAY 2

The P.H.D. Amateur Radio Association, Inc. will sponsor the Seventh Annual Northwest Missouri Hamfest Sunday, May 2, 1976 at the Kansas City Trade Mark, Exhibit Hall 3 (Old Municipal Airport Terminal Building) starting at 9 am. Admission $1.50 in advance, $2 at door. Refreshments available; swap tables for a fee; forums, contests, prizes, commercial exhibits, women's and children's programs. Talk-in on 34/94 and 3925.

WESTMINSTER MD
MAY 2

The Potomac Area VHF Society will hold their annual hamfest on Sunday, May 2, 1976, at the Agricultural Center in Westminster, Mary-

briefs

The FCC continues on its course of deregulation as Docket 20686 (see page 148) proposes deletion of rules concerning portable and mobile operation. The proposal would permit amateurs to operate portable or mobile without advance notice to the Commission and without having to identify as such. FCC monitors in several states have been citing amateurs for such violations as signing "mobile" instead of "mobile eight"; Washington apparently feels enough is enough.

In other FCC news, it appears that **ASCII 8-level teletype** code will be permitted in the very near future. Results from the AMSAT Special Temporary Authorization for ASCII on the OSCAR satellites have been favorable, while computers are becoming more and more popular among hams. Also, the 220 MHz CB proposal is dead. While it is probable that CB will be granted new frequencies, they won't be taken from hams. 220 MHz repeater activity is growing rapidly in many areas and is almost on a par with 2 meters in some areas.

One very probable place for **CB expansion** is on eleven meters. While there has been a rulemaking under consideration for some years to provide additional channels for CB sideband operation, the number of scofflaws operating above 27.3 MHz has been increasing rapidly, using bogus call numbers in the "HF" series as well as making up others. The FCC has been unable to handle the problem; legalization of the so-called "HF" band may result.

Gus Browning W4BPD has departed on another DXpedition comparable to the one he took over ten years ago. He promises to visit as many countries as he can afford to; Bhutan will receive special attention as Gus will be helping the government of that remote Himalayan kingdom to modernize their communications facilities.

Repeater/police interface idea catching on; groups in various areas are contemplating following the lead of several Chicago area clubs whose systems have a direct touchtone-activated tie line to the 911 dispatcher. Hams are thus able to treat autopatches as a public service rather than simply a convenience; this should counter some of the criticism received due to questionable uses of autopatch. Hams and the FCC are both uncertain as to what is considered acceptable on an autopatch, with citations given out in some areas for practices considered acceptable in others.

Good publicity for amateur radio in various newspapers, as WA2CFA and others arrange for emergency shipment of medicine to Ecuador to help save the life of a 1½ year old girl. A *New York Times* story described the efforts of the various parties to rush the drug to South America, with ham radio getting the leading role. Hams' massive Guatemalan effort has also generated great PR.

Microprocessor technology is leaping ahead with National Semiconductor's announcement of their new SC/MP chip. While slower than some other microprocessors, the SC/MP (simple, cost-effective microprocessor) is designed to sell for under ten dollars and require a minimum of interfacing. The object is to have a microprocessor included as a component in devices that ordinarily wouldn't, such as cash registers and appliances. Most hobbyist applications don't require much speed anyway, so the day of the hundred dollar computer system can't be far off. Other microprocessor prices are falling; Texas Instruments has announced their TI8080 chip, equivalent to other 8080 chips, with a price of under $35 in single quantities.

A "Treasure Hunt" coordinated by the Keene (NH) Radio Amateur Society recovered two sacks of canceled checks stolen from an interstate bus while en route to the Cheshire National Bank in Keene. About fifty Boy Scouts, with ten ham mobiles using 146.52 for communications, helped find the checks which the thieves, who thought they were taking cash, had ditched in the woods in Winchester.

The FCC has acted on **Docket 20119**, shifting the hundred milliwatt "walkie talkies" that may be operated without a license from the 27 MHz Citizens Band to 49.82-49.90 MHz. Manufacture of the CB units may continue for a year; use will be permitted until 1983.

land, between the hours of 9 am and 5 pm. There will be a registration of $3. Talk-in on 146.94 and 52. For more information contact K3DUA or WA3NZL.

BROWNFIELD TX
MAY 2

The Brownfield 76 Centennial Swapfest will be held on May 2, 1976 in the National Guard Armory, Brownfield, Texas. Door prizes will include a 2 meter FM rig and a Johnson Messenger CB transceiver. Advanced registration $1.50 and $2.00 at the door. Social get-together the evening before in the Armory. Write Viola Simmonds W5FBM, 1603 E. Tate St., Brownfield TX 79316 for info and/or registration.

SEABROOK NH
MAY 8

The Hosstraders Third Annual Tail-gate Swapfest will be held Saturday, May 8, at 11 am at Addams' Campground, Route 286, Seabrook NH off Route 95 at the Mass-NH border. Admission 75¢, dealers included, no commissions or percentages. Excess revenues benefit March of Dimes birth defects campaign. FM clinic sponsored by Saddleback Repeater Association. Talk-in .52, .40-00, and/or 3940 kHz. If any questions, SASE to WA1IVB, Box 32, Cornish, Maine 04020.

FORT WALTON BEACH FL
MAY 9

The Playground Amateur Radio Club will hold its Sixth Annual Swapfest Sunday, May 9, 1976, from 8 am until 4 pm at the Fort Walton Beach Fairgrounds. Registration $1.50 advance — $2 at door. Free swap tables. For hotel and other information write: Swapfest Committee, PO Box 873, Fort Walton Beach FL 32548.

JAFFREY NH
MAY 15

The 1st Annual Fly In and Flea Market will be held Saturday, May 15, 1976 at the Jaffrey Municipal Airport (Silver Ranch) in Jaffrey, New Hampshire. *73 Magazine* will host the event. Picnic facilities, food stand, great ice cream, horseback riding available at Silver Ranch stables across the road from the airport (200 yds). Plenty of hangar space for exhibitors, etc. Come one — come all — if you can't fly — drive — but get here. Jaffrey is 6 miles south of Peterborough on U.S. Rte. 202.

WEST LIBERTY OH
MAY 16

The Champaign Logan Amateur Radio Club is holding its 6th Annual Flea Market and Auction on May 16, 1976 starting at 12 pm at the West Liberty Lions Park at West Liberty, Ohio. Free admission, trunk sales and tables $1.00, door prizes. Talk-in on 146.52 and 146.13/73.

LAKE DELTON WI
MAY 22

The Yellow Thunder Amateur Radio Club will sponsor their 6th annual hamfest on Saturday, May 22, 1976 at the Dell View Hotel in Lake Delton, Wisconsin, starting at 10 am. Meetings and events include: swap shop, DX, VHF, RTTY, MARS, ARPSC, hidden transmitter hunt, ladies activities, liars contest and an evening banquet with entertainment including something new: "The Kitchen Maids." Grand prize: Regency HR2-B. Admission $7 in advance or $7.50 at the door. ($1.50 or $2.00 without the banquet.) For further information contact Kenneth A. Ebneter K9GSC, 822 Wauona Trail, Portage WI 53901.

SANDUSKY OH
MAY 23

The Vacationland Hamfest will be held on Sunday, May 23, 1976 at the Erie County Fairgrounds from day-break till 3 pm. Featuring — free camping Saturday night, free transportation to Cedar Point ferry boat dock. Bring the family and let them visit the greatest amusement park in the U.S.A. Plenty of flea market tables, dealers welcome, 8 acres for trunk sales. 1st grand prize: 1200 Watt ac gasoline generator. Tickets are $1.50 in

advance — $2 at gate. Flea market vehicles $1 each. For further information or reservations write: E.A.R.S., PO Box 2037, Sandusky, Ohio 44870. Call in on 52-52.

WABASH IN
MAY 23

The Wabash County Amateur Radio Club will hold their 8th Annual Hamfest Sunday, May 23, 1976 at the 4-H Fairgrounds in Wabash, Indiana. The hamfest will be held rain or shine. There will be a large flea market (no table or set-up charge), technical forums, bingo for the XYLs, free overnight camping with ac hookup, and plenty of parking. Lots of good food at reasonable prices. Admission is $1.50 for advance tickets, $2 at gate. For more information or advanced tickets write to Bob Mitting, 663 North Spring Street, Wabash, Indiana 46992.

POTTSTOWN PA
MAY 23

The Pottstown Area Repeater Team Hamfest and Flea Market will be held on Sunday, May 23 at 9 am to 4 pm at Rt. 422, Hiway Drive-in 8 miles east of Pottstown. There will be prizes, auction, contests, and refreshments. Talk-in 52/52, 81/21, 66/06. Registration $2 — tailgate $1. For more information contact A. Jefferson WA3VYS, 444 Roland Avenue, Pottstown PA 19464.

KNOXVILLE TN
MAY 29-30

The Radio Amateur Club of Knoxville will hold its annual Greater Knoxville Hamfest on May 29 and 30th at the National Guard Armory, 3330 Sutherland Ave., N.W. Activities will include an indoor and outdoor flea market. Door admission $1 and a chance for a door prize. Tables and space rental for indoor flea market will be $2.50 per table. There will be a banquet on the 29th at 8 pm at Howard Johnson's, West Town at $6 per person. Talk-in on 16/76 — 34/94 and 3980. More information by SASE from Edward L. Melton WB4JGF, 749 Elkmont Rd., Concord TN 37922.

BURLINGTON KY
MAY 30

The Kentucky Ham-O-Rama will be held Sunday, May 30, 1976 (Memorial Day weekend) at Boone County Fairgrounds, Burlington, Kentucky. Ten minutes south of Cincinnati, Ohio near I-75. Prizes, forums, XYL program, exhibits and flea market. Tickets $1.50 advance. For more information contact: NKARC, PO Box 31, Fort Mitchell, Kentucky 41017.

It Happened to Me...

Charlene Knadle WB2HJD
316 Vanderbilt Parkway
Dix Hills NY 11746

I decided to improve the hamshack. The O.M. was out and there couldn't be a more perfect time. The Fibber-McGee hamroom closet was sixty percent empty. O.M. and friends were on a mountain-topping expedition, and they'd packed like it was for forever. I had time. They would be gone the entire weekend.

Lug the rest of the heavy stuff out of the closet. Clean the floor — hadn't been vacuumed since we moved in (too equipment-covered).

Bring up a steel-shelf unit from the basement. Wouldn't miss one there. Put it in hamroom closet. Fits fine. Lug the heavy stuff back into closet — this time onto lowest shelf.

Add another bookcase — this one wood-grained and handsome. Fill it with *QST*'s, *73*'s, *Ham Radio*'s and *CQ*'s (O.M. needs them for quick reference while on the air) so there won't be space left for voltmeters, power supplies, and supply supplies.

Dust and wax desk and two tables. Clean floor. Stand back and admire. What could be better than this? Something could. There could be an acoustical ceiling.

Too bad I thought of it.

OM returns aghast and delighted. Adds pegboard back to closet. Puts things on shelves *neatly*. Devises wire-hanger for side wall. Progress!

Pass the word I want egg boxes to use as acoustical tiles. NASTAR office says they seem to work (NASTAR, we remember you), though they never measured to be sure. Friends and relatives give egg boxes. Especially Grandmother, whose friends run a delicatessen. Can't just tack them up. Got to paint. (Worst mistake).

Line basement floor with newspapers; spread the cartons. Dab the paint, twist; dip, dab, twist. Slow going. Must be a better way. An idea lights. Use an insect sprayer. Got one for $2.39.

"Why don't you just buy ceiling tiles? The suspended ones are great."

"The idea is to do this *cheaply*."

"Have you considered your labor?"

"I want to do something *different*. Be *creative*."

"You don't even know if it'll work."

"We'll measure it."

"Why paint first?"

"I've already started. Leave me alone."

Remove insect-sprayer cap. Hole small. Sacrifice soup ladle and kitchen funnel. Fill it. Push! Hard going. Clogs. Paint too thick; hole too small. Scratch $2.39 plus ladle and funnel. Back to the brush. Dip, dab, twist; dip, dab, twist. This is going to take forever.

Six painting sessions later, enough done to cover one fourth of hamshack ceiling. Tall stack unpainted; short stack painted, wet ones on floor.

Enthusiasm not lost, just new projects gained. Let it ride. Months later: "I'm not so sure I like the idea. Why don't you drop it."

"Never. After all those people contributed cartons? After all my work?"

"Think of what there is yet to do."

I did. And I didn't do. Too many other things. (Sew, study, have another baby.)

Rain seeps into basement. Dries. Seeps again. Dries. O.M. disgusted with clutter *there* (of all places). Goes on binge. Cleans unmercifully. Fills garbage cans. Sells valuable gear. I'm busy upstairs.

"By the way," (weeks later) "I threw away those old egg cartons. It would never have worked. And you weren't going to finish them anyway."

Could he be wrong? (Might it work?) Anyone want to find out? ■

555 Timer Sweep Circuit for SSTV

The circuit described in this article uses a 555 timer IC chip as both the oscillator and linear sawtooth generator circuit for an SSTV monitor. Most SSTV monitor sweep circuits that have been published use a transistor-discharged capacitor sweep circuit to produce the 15 Hz and 1/8 Hz sawtooth waveforms required for horizontal and vertical deflection. Separate oscillator circuits are required to drive the discharge transistors to produce a raster in the absence of sync pulses, or else the beam will stay at maximum deflection until sync pulses return.

I have been intrigued for some time with the 555 and its versatility in many applications. So, when I was building my SSTV monitor, I decided to experiment to see if the 555 could be successfully used as both the linear ramp generator and oscillator.

The entire sweep oscillator circuit described uses a pair of 555s, one for the horizontal sweep, and the other for the vertical. A single 556 chip, which is merely two 555s in a single 14 pin DIP package, could also be used.

The 555 Timer

For those not familiar with the 555, let me first describe its basic design and use as a simple oscillator. Such information is basic to the understanding of the SSTV sweep circuit.

A block diagram of the 555 is shown in Fig. 1. It contains a precision voltage divider string consisting of three equal resistors, two comparators, and a control flip flop. Also included are an inverting buffer amplifier capable of sourcing or sinking 200 mA and a discharge transistor whose collector is available at pin 7. The comparators set or reset the control flip flop when their inputs are equal to 2/3 or 1/3 of the supply voltage, respectively. When the flip flop is in the "set" condition, the output on pin 3 is at ground and the discharge transistor is "on" in the saturated condition. The 555 is available in an eight pin "Mini-DIP" package or in an eight lead TO-5 can.

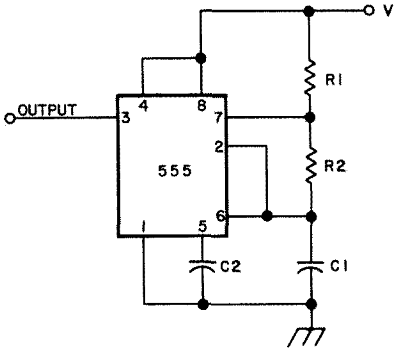

Fig. 2. Basic oscillator.

Basic 555 Oscillator

The use of the 555 as an astable oscillator is shown in Fig. 2. Circuit operation is as follows: Upon application of the supply voltage, which can be between 5 and 15 volts, capacitor C_1 will start to charge through R_1 and R_2. When the capacitor voltage becomes equal to 2/3 of the supply voltage, the threshold comparator sets the control flip flop, turning on the discharge transistor. The capacitor then discharges through R_2, until its voltage is equal to 1/3 of the supply voltage. The trigger comparator then resets the flip flop, turning off the discharge transistor, allowing the cycle to repeat. The waveforms produced are shown in Fig. 3. Since the comparator switching points are directly determined by the supply voltage, which also determines the charging rate of the capacitor, the oscillator frequency is insensitive to changes in the supply voltage. The oscillator frequency can be calculated by:

$$f = \frac{1.44}{(R_1 + 2R_2)\ C_1}$$

Capacitor C_2 is merely a by-pass to keep noise out of the reference voltages.

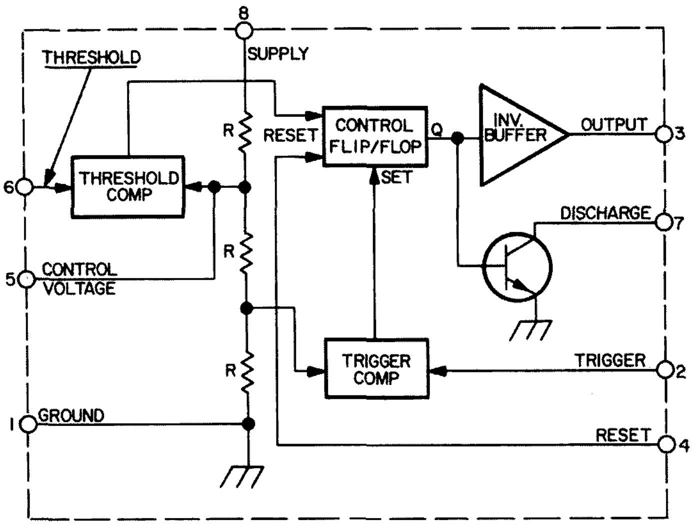

Fig. 1. Block diagram of 555 Timer Chip.

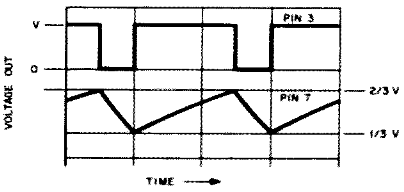

Fig. 3. Oscillator waveforms.

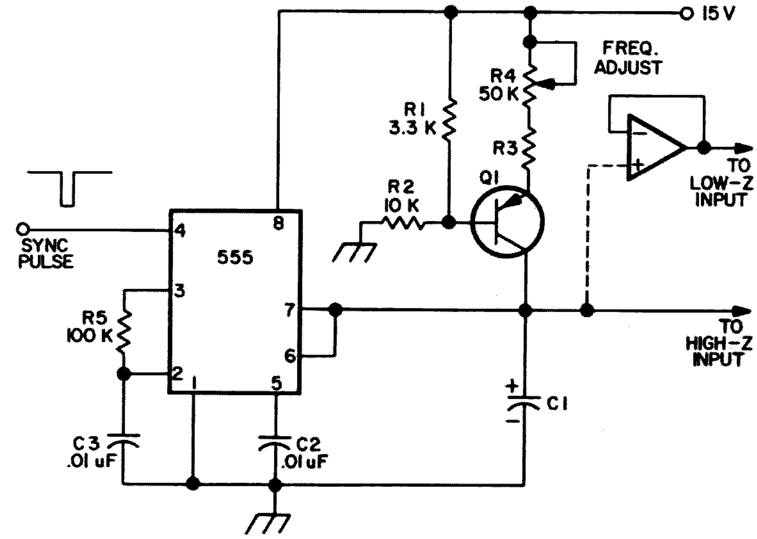

Fig. 4. Basic 555 sweep circuit. Q1 — 2N2907 or equiv.; C1 — 1 uF horiz., 10 uF vert.; R3 — 10k horiz., 250k vert.

Linear Sweep Oscillator

This basic circuit had some basic deficiencies which made it initially unsuitable for SSTV sweep application. The main objection was that its output waveform was exponential rather than linear. The other objection, rather minor, was that it did not return to zero but began recharging at 1/3 supply voltage. Both these problems were overcome with the circuit shown in Fig. 4.

Linear charging of the capacitor was achieved by using a transistor constant current source in place of R_1 and R_2. The collector current of the PNP transistor is constant as long as the capacitor voltage is not equal or greater than the base voltage, allowing the transistor to conduct normally. The transistor operates to maintain the same voltage drop across the emitter resistors R_3 and R_4. The collector current for a high gain transistor ($\beta > 300$) is for all practical purposes the same as the emitter current:

$$\frac{I_c}{I_e} = \frac{\beta}{\beta + 1} = \frac{300}{301} \approx 1$$

The result is a constant current that can be varied by changing R_4. The amount of current will determine the charging rate of the capacitor, and hence establish the oscillator frequency.

To allow the waveform to return to zero volts before restarting the sweep, the trigger

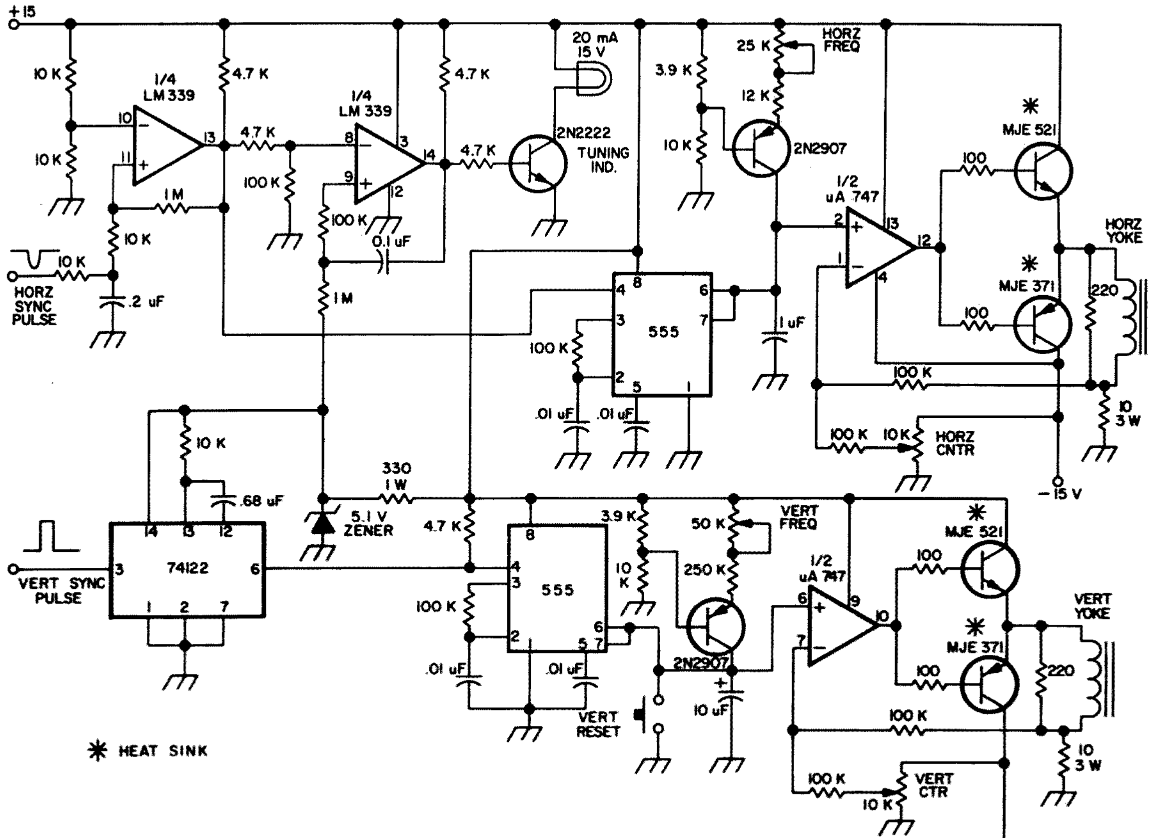

Fig. 5. Complete 555 SSTV sweep circuit.

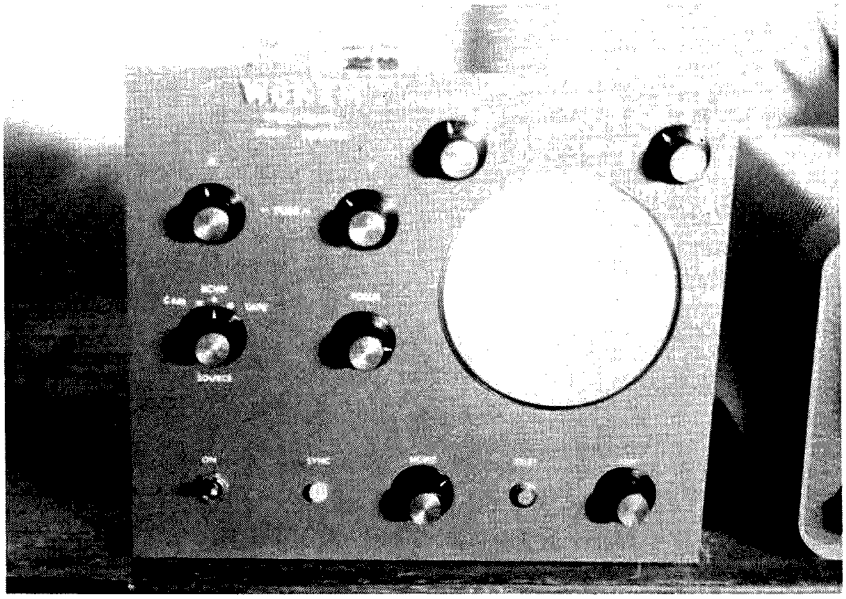
input was connected instead to the output, pin 3, through a delay network R_5 and C_3. Approximately 1 millisecond after C_1 is discharged and the output voltage goes low, the trigger voltage falls below 1/3 the supply voltage and a new sweep is started. The discharge of C_1 is quite rapid, allowing for rapid retrace. The 1 millisecond delay, however, insures that the capacitor does discharge completely before starting a new sweep.

In operation, the frequency of the oscillator is set by adjusting R_4 so that the period of oscillation is just slightly longer than the time between sync pulses. The presence of a negative-going sync pulse on the "reset" input (pin 4) will discharge the capacitor for retrace at the proper time and initiate a new sweep.

The sawtooth sweep is taken from pin 7. This is a high impedance point, and needs to be buffered with a voltage follower operational amplifier circuit if it must drive a low impedance input circuit. In this application, however, I was able to drive the positive input of the operational amplifier in the sweep driver stage without loading problems on C_1 or the current source.



Home brew SSTV monitor using the 555 sweep circuit.

Summary

The oscillator circuit is very stable, and will run very close to the correct frequency if sync pulses are QRM'd or otherwise lost. The "retriggering" aspect of its design makes it possible for the sweep to lock in again instantly on the first new pulse after previous pulses were lost.

Fig. 5 is a complete schematic of the sweep circuit used in my SSTV monitor. Included also in this circuit is a pulse "stretcher" and lamp driver that operates from the horizontal sync pulses and is used as a tuning indicator. The circuit has been in use in my home brew SSTV monitor since November 74. The rest of the monitor is basically the W9LUO[1] design. The operation of the 555 oscillator/ramp generator has produced good results and stable pictures under many adverse conditions. ■

from page 12

Ramada Inn in Culver City was contacted and they provided a room and telephone facilities. A portable two meter station, operating under the club's W6GAA callsign, was activated from that location on the club's WR6ABB repeater and all normal repeater activity other than that of an emergency nature was suspended. In place of the normal 'ABB activity, a PARC sponsored "Guatemalan Disaster Relief Net" was called. The purpose of this net was to take traffic input from all over the LA area, collate this traffic as to type (i.e., priority, emergency, health and welfare, etc.) and then disseminate same to the proper channels for delivery. Shelly WB6KED, who had already been working with the consulate, was dispatched on a rather permanent basis to set up a portable two meter station at their location. With the generous cooperation of Mr. John Smith, Supervisor of Airport Operations at Los Angeles International Airport, space and power was made available for a portable station to be set up at the Pan American Airlines terminal. This station was initiated and manned by a non-PARC member who volunteered both his equipment and time to get things started: Mr. Bill Orenstein KH6IAF/6, mentioned earlier in this column, along with the assistance of his "date" for the evening, Miss Karyn Ericksen. Bill and Karyn began the airport operation around 6 pm Saturday afternoon and continued on to about 5:30 am Sunday morning when relief operators finally arrived. The Pan Am terminal was chosen since they are the only carrier from this area with regularly scheduled flights to Guatemala City and were therefore bearing the brunt of the transport job of both people and supplies. Many people with relatives were going to that terminal in hopes of finding a way to send a message "back home," and it was thought that a station set up for easy public access would be ideal at that location. It was.

As soon as everything was ready to go, Lenore Jensen W6NAZ, Chairman of the Southern California Amateur Radio Public Relations Committee, was asked to contact the news media and pass along the location of the airport station and the "Command Center" telephone number. In short order, the majority of Los Angeles broadcast media outlets were carrying the necessary information to the public and things began to get busy. While no exact figures are yet at hand, in the two days that this phase of the operation took, approximately 2,000 messages were collected and placed en route to Guatemala in two ways. Emergency and priority traffic was immediately handed off to stations in direct HF contact with Guatemala through a number of HF Disaster Relief Nets operating 20 meters during the day, and 40 or 80 in the evening. Through the efforts of WB6VDE, WA6IFU and WA6CPS, a portable 80 meter station was set up in the Ramada Inn parking lot housed in Roy WA6CPS's van; however, most of the aforementioned high priority was handled by other volunteer stations, many non-PARC members. Word had spread quickly as to what PARC was doing and the necessary HF stations soon made their presence and willingness to help known.

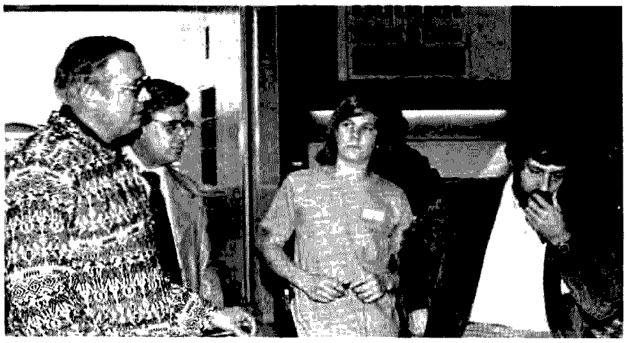
Health and welfare of a non-priority nature was handled in another way. The majority of it was placed in the hands of the crew of an airliner en route to Guatemala City with instructions that it be delivered to the proper authorities down there. This was done to alleviate the strain on the HF nets so that they could handle traffic on the aforementioned priority level. Two such packets went out on Sunday the 8th – one at about 9:45 am and another about 9 pm with the final batch to follow this coming am. At around midnight Sunday, this phase of the operation was terminated. I say this phase, since there will be more to come in the days and weeks ahead. We will continue to run communication liaison for the Consul General, accept and disseminate return communication, keep information on what is transpiring headed to the media, and anything else we are called upon to do. In fact, earlier this evening Dan and I found ourselves working hand in hand with both the Guatemalan and Panamanian Consul Generals weighing relief supplies in the Pan Am air freight building prior to shipment. Earlier, I had found myself directing people who spoke little or no English to John WA6HQL, another non-PARC member who had been quick to offer his services when someone who was bilingual in Spanish and English was found a necessity at the airport operation. John spent about 10 hours cramped behind a desk writing messages in English that were being dictated to him in Spanish.

Recording it all at SAROC is the author, as captured in this photo by Mrs. ITF.

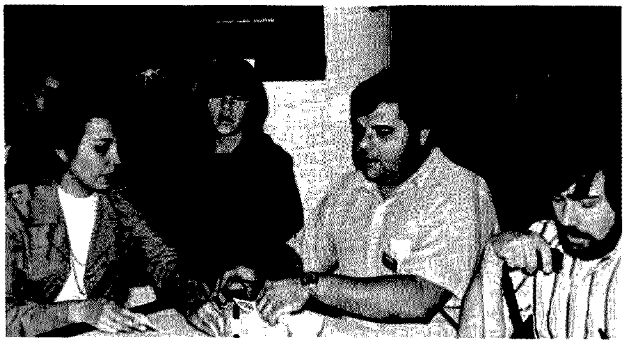
Then there was Bobby WA6ORR, who made sure that all operations had the necessary food to survive on. She ran around in the rain gathering donated food from McDonald's Hamburgers and Shakey's Pizza so that everyone would have lunch and dinner. As if that were not enough, she also spent about five hours manning a message-gathering position at the airport facility; the limited amount of Spanish that she knows was sure handy. The list of volunteers for this operation goes on and on and I could fill an entire column with just names. What's really important, though, is that when people in another part of the world were in need of help, people here, amateurs such as you, were able and willing to provide that help. Not only am I proud that PARC took on this humanitarian project, but I'm proud of every amateur and non-amateur alike that volunteered his or her time to make its success unquestionable.

I think that Karyn Ericksen may have summed it up best last evening when I spoke with her and Bill at the airport. To paraphase what she said: When things such as a disaster like this take place, one's instinct is to try and find some way to help. What these ham operators are doing is one of the finest and most sincere efforts she had ever seen and she was thrilled to be a part of it. There was no doubt in my mind that she really was impressed; the excitement in her voice was a give-away that she was witness to something beautiful.

Next month: A bunch of wrap-ups along with a meeting, so get ready for another long one. More on autopatches, the windup on WR6AJP, the windup on SAROC and what that beautiful guy Johnny Johnston K3BNS told us about future FCC plans, and the windup on this story along with coverage of the February 22 SCRA meeting in San Diego. Just may be some big surprises from that one. ■



Bill Orenstein KH6IAF/6 relays earthquake information from Dr. Stark of "Food for the Hungry" (one of the first returnees) to the Los Angeles Guatemalan Consulate.



"Operation Save-a-Nation": PARC's portable station at L. A. International. Here, John Barreiro WA6HQL translates a health and welfare message into English. More than 3000 messages were handled.

Tech Manuals

So! Now you're having second thoughts about that beautiful piece of electronic gear you bought at the surplus sale. It's beginning to look more like a boat anchor all the time. But, you say to yourself, if I only had a technical manual for it, I might be able to do something besides cannibalize it. Well, my friend, take heart. It is possible that you can get a manual for it. Public Law 90-23 allows the sale of unclassified technical manuals directly to the public. This article will tell you how to go about ordering a manual and approximately how much it will cost.

Each agency, i.e., Army, Navy and Air Force, is responsible for determining the releasability and cost of the manuals under its jurisdiction. In the case of the Army and Navy, each has a single office where you can send your request, but within the Air Force there are five different activities depending on the type of equipment involved.

Determining which of the first categories your goodie fits in will probably be obvious by the type sale where you purchased the item (Army, Navy, AF). If it is an Air Force item, you must further determine which activity in the Air Force can satisfy your request. But even if you goof and mail your request to the wrong place, no harm will be done, except maybe some delay in getting the information you want. Each service has a similar way of identifying its manuals: the Army precedes a number or group of numbers usually with TM; the Navy with NAVSHIPS; and the Air Force with T.O. If there is any reference to this type number associated with the equipment when you get it, by all means

mention this in your request. It may save you both time and loot, because if an agency has to perform research in excess of an hour or so to locate the number, you may have to pay for this research. However, most research requires much less time than this, so you don't have to worry about it.

The manufacturer installs a nameplate on each item of equipment before it is delivered. The nameplate contains, among other things, the Joint Electronics Type Designation Number or AN number as it is often referred to. This number tells you what the item is and, in the case of the Air Force, gives you a clue as to what activity is responsible for the technical manual.

As was stated earlier, if it is Army or Navy equipment, you need only mail your request to the appropriate address which is also listed at the end of the article. If it is Air Force equipment, mail your request to one of the five Air Force bases listed, after determining the appropriate one by reviewing the type equipment managed by each one.

Now for the cost. It is nominal as the government barely recovers printing costs. There is a minimum charge of $2.00 for manuals up to six pages and an additional one-cent-per-page charge for all pages in excess of six. For example, a manual with 100 pages would cost about $3.00. Be sure to specify what type manual you want, i.e., maintenance, operation, or parts list. Do not send any money with your original inquiry. As soon as the agency receives your request they will determine if a manual is available. If it is, they will notify you what the cost is, how to make out your check or money order and tell you where to mail it.

That's all there is to it, so don't let that goodie gather dust on the shelf. Get yourself a technical manual and put it to work.

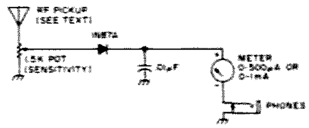
RF and Mod Monitor



Around most ham shacks, several uses can be found for a simple rf and modulation monitor. This one is little more than a glorified crystal detector, but it monitors outgoing rf, aids in the tuneup of transmitters and antennas and lets you hear how your transmitted signal sounds.

Of course, single sideband — if the carrier is properly suppressed — will sound through this monitor like you're talking with a mouthful of wet cement. Amplitude modulated signals should sound clean and natural.

I built this circuit in a small phenolic box measuring 3-3/4 x 2-5/8 x 1-3/8 inches. A metal minibox also can be used. The rf probe is 5 feet or so of #22 enameled copper wire folded and taped into a "whip" about a foot long and soldered to a phono plug. At low frequencies and low power levels, a longer piece of wire may be necessary for sufficient rf pickup. Most any germanium diode should work, but a 1N87 gave higher output than a couple of other general purpose diodes. ●

A Failure to Communicate

I may give up ham radio. Band conditions have been getting progressively worse and recently it's been so bad, I haven't even been able to get through a complete QSO.

Last week was particularly frustrating; for example, on Sunday I was talking to a TV weatherman out in six-land and he told me about a wealthy friend of his who'd spent a bundle on a fancy antenna farm. It had separate towers with monoband beams for each band and the rotors were powered by specially designed batteries. They required a critical amount of internal pressure which was provided by an external compressor unit.

It seems that during the recent DX contest this fellow left the compressor on and the batteries built up so much pressure that they exploded, sending all kinds of debris into the air.

Naturally, when I heard about that, I commented that the skies must have been partly crowded with shattered towers, due to a high pressure cell. I figure the band must have fallen out about then 'cause he didn't come back after that.

Then on Wednesday, I was up on Twenty, talking to a foreign sounding guy who kept referring to his transmitter as his E-mitter. He probably called it that because of its A-1 emissions (they sounded pretty good to me anyway). He told me about a run-in he'd had with the local tax collector who'd tried to impound his radio equipment. When they went to court over it, the judge, who turned out to be the tax collector's brother-in-law, told the ham to hand over his gear.

I asked him if the judge had a deep voice, and when I found out that he did, I said, "It's obviously another case of a short circuit from E-mitter to collector due to an improperly biased bass."

The band dropped out on us. ■

Docket 20686

Before the
Federal Communications Commission
Washington, D.C. 20554

In the Matter of

Deregulation of Part 97 of the Commission's Rules concerning portable and mobile operation of stations licensed in the Amateur Radio Service

DOCKET NO. 20686

NOTICE OF PROPOSED
RULEMAKING

Adopted: January 14, 1976;
Released: January 27, 1976

By the Commission:
Commissioner Lee absent.

1. In this Notice of Proposed Rulemaking the Commission proposes to simplify greatly the procedures involved in operating a station licensed in the Amateur Radio Service at a portable or mobile location. We propose to delete those sections of Part 97 of the Commission's Rules requiring that licensees operating their stations portable or mobile identify their transmissions as originating from a portable or mobile location. Section 97.313, concerning the station identification required of stations operated in the United States by aliens pursuant to international reciprocal agreements, would not be affected by the amendments proposed herein.

2. By way of background, an amateur licensee is presently permitted by Section 97.95(a) of the Rules to operate his station away from the permanent station location anywhere in the United States, its territories, or possessions as a portable or mobile station. Under Section 97.95(b) a licensee may, with certain restrictions, operate his station as a portable or mobile station outside the limits of the United States, its territories, and possessions. Sections 97.95(a)(3) and 97.95(b)(3) require that advance notice of such portable or mobile operation be given the Commission, pursuant to the provisions of Section 97.97, which specifies the content of the required notice, and states, further, that such notice need be furnished only if the contemplated portable or mobile operation is or is likely to exceed 15 days. Finally, Sections 97.87 (b) and (c) provide that the transmissions of stations being operated at portable or mobile locations be identified as such.

3. We believe those sections of the Rules cited in the preceding paragraph to be superfluous. Such requirements have never been shown to be of use to the Commission in its regulatory program, and while amateur licensees would in the future, as now, be afforded the option of operating their stations at portable and mobile locations, we perceive no purpose to be served in requiring advance notice to be given the Commission or in requiring that transmissions of stations being operated at portable or mobile locations be identified as such. We would stress, however, that in eliminating these requirements we would not be prohibiting those licensees wishing to do so from continuing to identify their portable and mobile transmissions in the traditional manner. We would simply no longer require it.

4. In proposing that the portable operation station identification become optional, we recognize the probable impact on certain amateur operating practices and operating award programs neither regulated nor sponsored by the Commission. For instance, under the proposed rules, the control operator of a station in portable operation at a location outside its fixed operation call sign area [§97.51(b)] would no longer be in violation of the Commission's Rules should he choose not to include the portable designator when identifying the station. In these instances, listeners would not be able to determine from the identification that the station was located outside the fixed operation call area. Call areas would, in a de facto sense, be partially eliminated. For this reason, we particularly wish to receive comments on the issue of whether those amateur operators who would otherwise not elect to identify their stations as being in portable operation should be inconvenienced in order to eliminate any impact upon ongoing amateur practices and programs. While adoption of this proposal might ultimately cause a substantial dilution of the significance of amateur call sign areas, it would provide the Commission with important indicia of the extent to which the Service is capable of self-regulation and the extent to which our deregulatory program is likely to be successful.

5. For the reasons cited heretofore we therefore propose to delete in their entirety Sections 97.87 (b) and (c), 97.95 (a)(3) and (b)(3), and 97.97 of the Commission's Rules. The remaining sections of Section 97.87 would be redesignated to reflect the deletions.

6. The proposed amendments to the Rules, as set forth in the Appendix, are issued pursuant to the authority contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended.

7. Pursuant to applicable procedures set forth in Section 1.415 of the Commission's Rules, interested persons are invited to file comments on or before February 27, 1976*, and reply comments on or before March 8, 1976. All relevant and timely comments and reply comments will be considered by the Commission before final action is taken in this proceeding. In reaching its decision in this proceeding the Commission may also take into account other relevant information before it, in addition to the specific comments invited by this Notice.

8. In accordance with the provisions of Section 1.419 of the Commision's Rules, an original and eleven copies of all statements, briefs, or comments shall be furnished to the Commission. Responses will be available for public inspection during regular business hours in the Commission's Public Reference Room at its headquarters, 1919 "M" Street, N.W., Washington, D.C. 20554.

FEDERAL COMMUNICATIONS COMMISSION

Vincent J. Mullins
Secretary

**This Notice was received too late for inclusion in the February, March and April issues.*

Please be advised that we have the unique situation of having recovered a Unimetrics Ultracom 25 with no obvious ID or serial no.

Would you please change your lost column in *73* to include "found"? Request that interested people contact David M. Stoner K8LMB, 619 Doepke Lane, Cincinnati OH 45231.

Keep up the good work with *73* – I love it.

Tracking the HAMBURGLAR

HIJACKED: RF Comm. Inc. RF-403 two meter transceiver, s/n unknown. 4 Chan. 80 Watts approx 4"h x 12"w x 12"d. Set up for MARS frequencies, 34-94 and possibly other amateur frequencies. Color is black. Please notify FBI or Wallace Moore WBØAWH, 12053 W. Virginia Ave., Lakewood CO 80223, phone: (303) 986-3909.

KIDNAPPED: ICOM IC230 two meter transceiver, s/n 2403009. Rig was taken without the mike on December 9, 1975 in Cleveland, Ohio. Contact Ferd H. Nye, Jr. WA8NXT, 31497 Hilliard Blvd., Westlake OH 44145.

ROBBED: SB-144 two meter transceiver, s/n 620962 with "W5PJ" stenciled on the set. The wires were cut and the set with microphone was removed. It was equipped with 34-94; 94-94; 16-76; 22-82; and 52-52. It also had county and one city receiving police frequency. Taken on January 17, 1976. Please contact Dr. Shailer Peterson W5PJ/K4HL, 5511 Keystone Drive, San Antonio TX 78229, phone: (512) 684-0449.

ABDUCTED: Heathkit HW 202 two meter transceiver, s/n 07429. Taken from auto of Dick Cullen WBØAGT. Mike has broken switch bar. "Stolen from WBØAGT SSN 410-66-8452" engraved on back. Has home brew synthesizer installed on top of set in mini box approx. same size as HW202 and is painted black. Has 2 RG-174 interconnect cables. Xtals installed: 37-97, 34-94, 28-88, 07-67 and 52-52. Please notify Dick Cullen WBØAGT, 1515 Newcastle St., Colorado Springs CO 80907, phone: (303) 598-1849.

LIFTED: HR-2 Regency two meter transceiver, s/n 04-02689. Xtals installed: 34-94, 94-94, 16-76. Please notify Dick Sucher WAØZLY, 3410 N. Prospect St., Colorado Springs CO 80907, phone: (303) 473-4186.

LOOTED: Unimetric Co., Ultra Com 25 – 12 chan. two meter FM transceiver, s/n 080-114. Taken from car in Akron, Ohio on September 12, 1975. Contact Herman Freeder W8VQI, 944 Jason Avenue, Akron OH 44314.

RUSTLED: Heath HW-202 two meter transceiver. Crystals installed: 34/94, 94/94, 07/67, 16/76, 88/88. Can be identified by wrong size wire on PC board, modulation is set HOT, so normal use will clip out on repeaters. Please do not discuss this incident on any of the above frequencies. Stolen from Doc. A. L. Stigers, Golden CO 80401, phone: (303) 237-3296.

LETTERS

from page 100

couldn't turn that down. I feel that my experience in coming to see how radio has enriched my life, not just my husband's, might have some effect on other XYLs. It seems to me that you fellows are missing the boat in not bringing in the nearest and dearest to swell the ranks. Our instructor has his wife helping him in class as well as his two sons, all of whom have their own licenses. They made it a *family* hobby! With all the talk about bringing in more people, why not begin at home? You may counter by telling me that wives don't feel they can hack it (I know); that they are really not at all technically inclined (I know); that they don't have all that time to yak (me, too), etc. Would you be interested in an article of two from me? My first title could be "Confessions of a Formerly Ambivalent XYL," followed by "Confessions of a Formerly Ambivalent Novice," or something like that.

I am as surprised as you may be to see this offer — I really don't need anything more to keep me busy, but I do feel I have something to say to hams and their families. Another point I want to make is the fact that radio should be a very appealing hobby to lonely people. Here in California there are so many singles and families who have little community involvement due to being transplanted or to shyness or what have you. They would constitute a tremendous number of people who could be brought into the radio family and it would enrich their lives a great deal. I see these people in my piano classes at night school and my women's chorus sings at hospitals, churches and clubs, where the same observation goes in spades. I could wish that the code were not so absolutely necessary and that the exams were not so difficult (you get the idea sometimes that the FCC is deliberately trying to trick you on the answers). However, I can also understand the pride hams have in having mastered their skills themselves and their consequent unwillingness to bring in others with less skill. Sometimes, people have to compromise with reality, though, if they really want more members in the group.

I personally feel that the public relations for ham radio is stuck in old concepts and needs to be brought up to date and broadened — lots more people of all kinds could benefit from the friendliness and increased people-to-people communication. This is undoubtedly one of the reasons for the wild rush into CB. As to upgrading skills, I feel that an appeal to more specific talents could be made from the broader beginning base. People seem to love awards. Even if they came into ham radio without code, they could be motivated by awards and contests to learn it just for the hell of it — rather than making it a grim requirement which turns off quite a few. Frankly, I think that it would not be too difficult to teach code to anyone but for the psychological component. I work against this everyday in my own classes — the no-confidence syndrome. Incidentally, I have had absolutely no background in radio and I avoided math and science classes like the plague when I was in school. I was convinced that I was a moron in math and had absolutely no ability in technical things. I do believe that I have above-average intelligence and I am stubborn when I make up my mind to try something. I have been advised to memorize the handbook in order to make the General exam, but I prefer to try to understand what I am doing instead. It has already given me quite a lift to discover that I have been psyching myself out all my life and that I can, with study, learn some of these things which I formerly believed the province of men. I am sure that I represent many other women in this respect. I am also remembering the wistfulness I have heard in the men's voices on the radio telling my husband how great it is that I am joining him in class, how much they wish their wives would do the same. How about it, do you think we can make radio more human to XYLs?

Froma Reiter WN6IWT
Fullerton CA

P.S. Obviously, none of this could have come about for me without my husband's strong, warm support and his obvious pride in my accomplishments. He bragged about my getting the Novice license so much that I was sure my blushes could be heard over the air waves. Whether you are interested in any further confessions, thanks for listening.

Sounds great, Froma . . . let's see those articles and maybe we can get more XYLs into the act . . . and on the air — Wayne.

"God Bless You All"

In the hours following February's earthquake in Guatemala, the only news reaching the outside world of the catastrophe emanated from a small group of amateur radio operators in the stricken country and in the United States.

The communications chaos was such that it fell upon these hams to inform the Red Cross, the State Department, the Guatemalan embassy here and other organizations of the extent of the disaster and the type of assistance needed.

One of the first on the air was Clyde Stanford, who works for the Central American Mission in Guatemala City. He roamed the city in his short wave equipped car, giving vivid accounts to the outside world of the devastation.

Monitoring Stanford in Miami was the amateur radio listening post of the Dade County Chapter of the American Red Cross, which immediately relayed his reports to Red Cross national headquarters here.

The damage figures given by Stanford over TG9LW (his station's call letters) and by Don Fiester, another amateur in Guatemala City, over TG9DF, were at first thought to be highly exaggerated.

Later information, however, proved they were understated if anything.

In the days since the earthquake, the amateur operators have turned their attention to obtaining health and welfare inquiries from people in this and other countries worried over the fate of relatives and friends in Guatemala.

Among the ham operators here who have been on the air almost continually since the disaster is Lewis Bloch of suburban Fairfax Station, Va. For a brief period following the quake, he was a main source of information for the Guatemalan embassy on the events taking place in the homeland.

Now Bloch, who is a publisher working out of his home, is handling welfare messages by the dozens. Typical is one for the American Red Cross.

The organization was contacted by John S. Whiting of Deerfield, Ill., whose son was working at the Spanish School in the city of Antigua when the disaster struck. Concerned that he had heard nothing about the boy's fate, he called the Red Cross here.

Within an hour, Bloch was on the air, asking amateurs in Guatemala if they could provide some information about the younger Whiting.

Bloch is an old hand in disaster situations. When an earthquake struck in Nicaragua a few years back, he recalls that he was on the air for days relaying reports and requests for assistance.

Another amateur, Joseph W. Miller, Bloch's next door neighbor, has handled over 200 messages since the earthquake, working as a volunteer for the Fairfax County Chapter of the Red Cross. As Bloch puts it, "Miller has been the workhorse on the operation."

Bud Fink, chief of radio communications for the American Red Cross, has nothing but praise for the ham operators. Through an agreement the organization has with the ARRL, the operators funnel vital information to the organization not only on foreign but domestic disasters as well.

The American National
Red Cross

* * * * *

The cold statistics of death and destruction from last week's earthquake in Guatemala caused days of anguish to thousands of relatives in the United States, but ham radio stations in both countries have begun to bring relief to some, grievous certainty to others.

At the Hall of Science in Flushing Meadow, Queens, volunteer operators yesterday manned Amateur Radio Station WB2JSM to relay scores of inquiries from anxious relatives in the Metropolitan area and incoming responses from fellow hams in Guatemala and the Red Cross station in Miami.

"Some of the news, fortunately even most of it, has been good," said Robert C. Reiley, call letters WB2FHN, the executive director of the Hall of Science and a radio buff since 1939. "But there's been bad news as well."

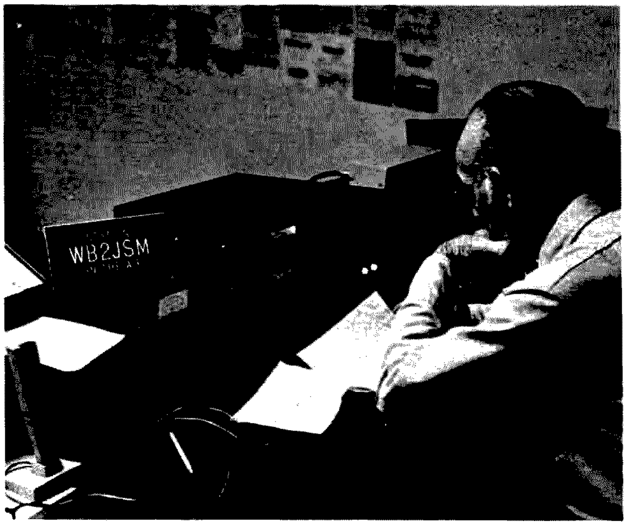
GOOD NEWS

Mr. Reiley said that the station he was manning was in touch with about a half dozen English-speaking hams in Guatemala, including a young Californian known as Joanne K6GFW, who operated with a portable radio transmitter and emergency generator from her home just outside Guatemala City.

Among the good news received from Joanne, Mr. Reiley reported, was a message for a family in Elmhurst, Queens, whose daughter, a registered nurse married to a Dutch United Nations official, had not been heard from. Her father, Earl Cosgrove, said last night that the young couple, Ruud and Marie Anne Ooye, were in Guatemala last Wednesday when the earthquake struck.

John Gorman WB2ROF sends traffic to Guatemala City, while anxious relatives wait for reply.

Martin Schwartz W2EPZ, a 44 year veteran of ham radio, prepares traffic to be sent to Guatemala.



Photos courtesy of Rick Moran WA2BBG, Photo Associates, New York.

"Even the U.N. couldn't get them," Mr. Reiley said, sitting at his bank of radio equipment with two other volunteers, Conrad Eiselen WB2FGB and Dan Algeri WA2MXI. "But we got through all right."

NUMBER HELPS

He said Joanne had been able to find out for the Cosgroves that their daughter was well and working in an emergency hospital in the Guatemalan town of San Lucas.

Mr. Reiley said most of the nearly 200 inquiries relayed from Flushing Meadow Park up to last night were from Guatemalan residents in this area. He said the station, the most powerful of its kind in the city, would be operating again today from 10 am to 10 pm and could be reached by calling 699-9400.

"If we have a telephone number to call down there, that helps," he said. Inquiries without telephone numbers would be routed via Miami and Pan American World Airways, which volunteered to take the messages to Guatemala City several times a day, Mr. Reiley reported.

The station, in the Hall of Science, normally serves to demonstrate amateur radio operations for visitors and tourists. According to Mr. Reiley, the hall and the station now shut down Mondays and Tuesdays, because of the city's financial straits, even though it is operated by a private nonprofit body.

NEWCOMER COMMENTS

But because of the Guatemalan disaster, volunteers like Mr. Reiley come in to operate the station as they have in previous emergencies, such as the earthquake in Nicaragua, in 1972.

One of them, Mr. Eiselen, is a 71-year-old retired service manager who got his license a few years ago from what Mr. Reiley termed the largest amateur radio school in the United States, an adjunct of the Hall of Science.

"I'd been fooling with shortwave radio ever since I was a kid," Mr. Eiselen remarked, "but I always wanted to become a real radio ham." He said that if Mr. Reiley needed him again today, he'd be there.

* * * * *

At 4:04 am on February 3rd, a killer earthquake dealt a swift and unsuspecting blow to the sleepy country of Guatemala.

Roofs, walls and entire buildings crashed down, killing, injuring and trapping thousands of citizens of Guatemala City and surrounding towns and villages. Power, water, and telephone lines were disrupted by falling buildings. Fires in various parts of the city burned out of control for the lack of water pressure in fire fighting.

Frantic searches began for friends, relatives and loved ones. Muffled cries could be heard from persons buried in tons of rubble. Men, women and children dug frantically among fallen structures to help those trapped beneath. Far too often, help arrived late, as another individual died.

The initial hours were the worst, for no one knew the extent of the damage. With nearly 100% of communication facilities disrupted, the only way for messages entering or leaving the country was via radio sources. Unfortunately, most radio communications were inoperative due to the lack of emergency power.

Once the news of the disaster reached the amateur radio community, hams in the western hemisphere, and in the United States particularly, focused their attention and abilities on the shaken country.

The disastrous earthquake gave hams another opportunity to show dedication and expertise in establishing communication channels to facilitate the passing of emergency traffic between the U.S. and Guatemala.

Previous experience in traffic handling through the Red Cross, AREC, Local, Area, and Regional NTS gave hams the confidence and practical experience to step in and set up communication networks within hours of the disaster. This proved the effectiveness of the National Traffic System in training operators to handle messages during an emergency.

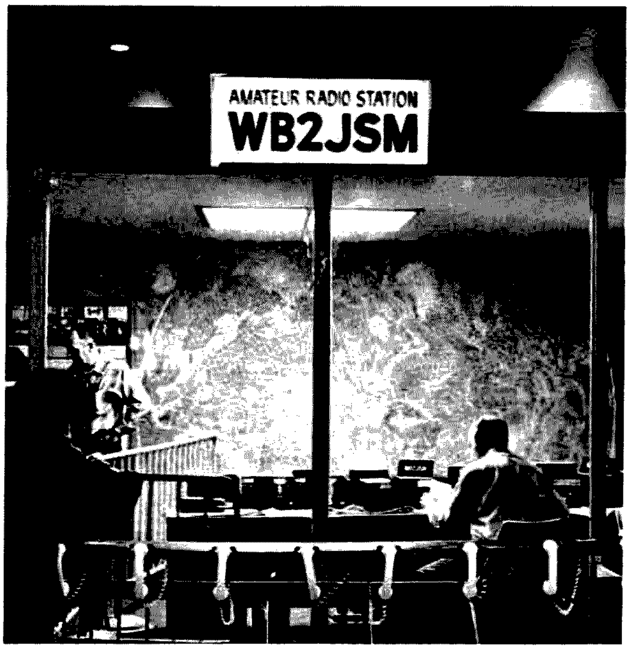
Hundreds of ham operators across the American continent were actively participating – either passing/receiving traffic, or assisting by monitoring emergency frequencies.

Many amateurs know the correct operating procedures used during an emergency, and, by virtue of their experience, are a helpful asset to the net control station who is trying to coordinate the incoming/outgoing traffic.

Others who are not acquainted with traffic handling can turn a smooth operating net into a nightmare. Many hams who participated in the Guatemalan crisis know of this first hand.

It is hard to state the exact rules of emergency operation that should be observed. Each situation may be different. However, there are general rules that should be followed.

1. *QRM.* Do not transmit without listening. This is probably the most important rule to follow explicitly. Many times during the Guatemalan crisis, amateurs would break in and call CQ or ask what net is in operation. Someone would have to tell the fellow he is on an emergency net, thereby adding additional QRM to answer his question – or net control would have to tell him to stand by until he could pick him up. In most cases, portions of traffic would have to be repeated because one person did not listen before transmitting. Multiply this by several hams doing this every five minutes and you can begin to understand the problems it causes in net operations.



Kids and adults monitor the traffic from station WB2JSM by using handsets provided, while station personnel collect and call out traffic within.

Another unforgivable amateur "sinner" is the ham who calls net control and says, "This is WA5???. I am just standing by listening. Can I be of any help?"

If you are really interested in helping, you will monitor the frequency until a request for assistance is transmitted by net control.

Remember, only you can keep the QRM level down.

2. *Accuracy.* In message handling, this is all important. Do not try to impress the station you are transmitting to by sending beyond their copying speed. If you are receiving the message and the station is going too fast, ask him to QRS. It takes just as long to answer requests for "fills" as it does to send at an appropriate speed the first time.

After trying a full day to deliver a message to California from Guatemala via land line, I finally asked the operator to check the number. Because one digit was transmitted incorrectly, a mother had to go through another sleepless night before she learned that her son was alive and well.

Remember, speed is not requisite, but accuracy is.

3. *Authenticating messages.* During an emergency, all messages, and especially official ones, should be written and signed by the originating party. A telephone number on the message where the signatory party can be reached is also advisable. This is normal procedure for routine messages during an emergency, too.

Remember, you are responsible for all messages transmitted from your station. So be sure your messages have authenticating signatures.

Message handling is not everyone's forte, but if you want to be of service during an emergency situation, at least inform yourself of the correct operating procedures.

There are two very helpful booklets that may be ordered from the ARRL: *Operating An Amateur Radio Station* (THE COST IS A NOMINAL 50 CENTS) and *Public Service Communications* (FREE). These two booklets will give you everything you need to know except the practical experience which comes with on-the-air operation.

I don't believe I will ever have a higher satisfaction than having been able to deliver a message to someone to tell them his loved ones were alive and well.

One memorable phone call to a Spanish-accented lady will always mean something special to me. When she answered the phone, the operator said, "This is a long distance collect call from an amateur radio operator who has a message for you from Colonel Juan Ortega (name changed) in Guatemala Cit . . ." The operator had not finished the sentence when the excited lady interrupted saying, "Oh yes, yes. That's my son! That's my son!"

Once I delivered the message informing her that her son was alive and well, she said, "You will never know how much it means to me to receive this message. Ever since the earthquake, we didn't know if our son was alive or dead. God bless you for helping to find my son – God bless you all."

A Representative Democratic Republic?

Not long ago, the ARRL, through *QST*, announced its interest in becoming involved in repeater coordination. Their idea was to appoint regional ARRL frequency coordinators to either work with existing councils or, in some cases where no coordination exists, become the coordinating facility. It was stated that the reason for this was to recognize the fine work now being accomplished by individual coordinators and/or coordinating councils and thereby give official League backing to this work. While I totally agree that official League recognition of repeater coordination efforts will lend a lot of much needed credence to this work, I and others I have talked with are bothered by two distinct things. First, it is not clear who would be "top dog" in such a setup: the existing council or the ARRL-appointed coordinator. If a case should arise in which the two found themselves diametrically opposed on a given matter, whose decision would be final? Secondly, the concept of "appointing" a person to this position by an organization outside a given area, rather than permitting all interested amateurs from within that geographic area to "elect" one of their peers to that position, does not seem exactly fair. The very reason for the success of most coordinating councils has been the fact that they are elective bodies rather than appointive. Thereby, every amateur involved in such efforts feels that, through the electoral process, he or she does truly have a voice in matters.

Finally, I consider the League proposal a bit shortsighted in that it is designed only to recognize repeater frequency coordination and is thereby not totally representative of all VHF/UHF oriented amateurs and all VHF/UHF operation in various modes. For example, it gives no assurances whatever that the rights of non-FM interests will be protected in the future. It is my feeling that any large scale frequency coordination effort must be total. It must not only be voluntary and elective, but must also represent every special interest and mode operating VHF/UHF, including such specialties as ATV, SSB, OSCAR, RTTY and yes, even AM. It must guarantee some voice to all, since it will be the amateur — not the League or any organization — that will ultimately decide the destiny of any band and mode.

Now please don't think that I doubt the League's sincerity in this matter; quite the contrary. I strongly believe that the League is sincerely looking out for the welfare of the overall amateur community. Frankly, I know of no other individual or group within our community with the capabilities of properly representing us to Washington and to the rest of the world. If I felt any other way, I would not have joined it. About the only thing that bothers me in regard to the League is their "hang-up" on having to always "appoint" rather than elect, especially to positions such as we are now discussing. In my mind, the position of League Area Coordinator is as important as the position of Division Director. He or she will be holding a good part of a given geographic area's VHF/UHF spectrum utilization in his hands, and therefore I feel that those affected by decisions of such an individual should have the ultimate decision as to just who such an individual will be. But, is this still the best way — or is there another alternative? I think that there is.

The idea that I am about to pass along is just that: an idea. A starting place from which to go forth. Admittedly, it has faults (no plan is perfect), but it meets two prime prerequisites. First, it is as close to being perfectly democratic as is possible. Other than for procedural matters, there is no single individual appointed by any other group or individual. From the local "grass roots" level to the upper echelon, all those serving are elected by their peers, elected by their fellow amateurs as their representatives. Secondly, it allows amateurs involved in VHF and UHF to totally determine, within the framework of the Commission's Rules and Regulations, the future development of that part of the amateur spectrum. In this way, we can be assured of uniformity in nationwide growth and thereby provide positive leadership and direction internationally. Starting to sound interesting? Well, all this is possible only if all amateurs interested in the future of VHF and UHF communication are willing to get involved.

Total involvement of all interested amateurs is the simple key. The idea is to build a national voluntary frequency coordinating council, one that would not only look out for the welfare of repeaters, but also would represent all aspects of VHF and UHF operation. Refer to Fig. 1; this is how it would be built. A city, state or other geographic area interested in working on such a plan would form "Workshop Groups" made up of individual amateurs of similar interest. These "Workshop Groups" could take the form of local coordinating councils such as we now have only for repeater owners, or perhaps the less formal "club" approach. Since I live in Southern California, let's use it as an example. Southern California is a given geographic area with two functioning VHF coordinating groups already in existence. Two meter and 220 MHz repeater systems are coordinated by the Southern California Repeater Association, while systems on 50 MHz and 450 MHz and up are the coordinating job of the California Amateur Relay Council. Such organizations as these would continue to operate without any change except for one small item, this being the election by the general membership of such organizations of a representative to a regional coordinating body to be described later on.

Now let us suppose that there soon developed a lot of SSB activity on two meters (and such is quick becoming the case in many parts of the nation as multi-mode transceivers such as the Multi-2000 and and TS-700, to name but two, proliferate among the amateur ranks). An area SSB users Workshop or Council could be formed locally to set up specific guidelines as to operational parameters of this mode, if the amateurs involved thought it was necessary. For example only, let's assume that the SSB Coordinating Council decided that a number of specific frequencies should be voluntarily set aside as designated calling frequencies. In a like manner to the repeater council, they could coordinate the same and ask that all amateurs voluntarily, and that word must be underscored, *voluntarily*, respect these allocations. We must never forget that no one amateur or group of amateurs owns or has a god-given right to any specific frequency.

RTTY enthusiasts, ATVers, AMers, OSCAR users, etc., could form their own representative area group to coordinate efforts of amateurs involved in that given mode and/or band. Regularly, these area groups would have their elected representatives meet locally to discuss and hopefully solve on a local level problems either between or common to some or all. They would learn to interact with each other and develop lines of communication that would be of mutual benefit. Never again could an amateur say, "Well, I was not asked my

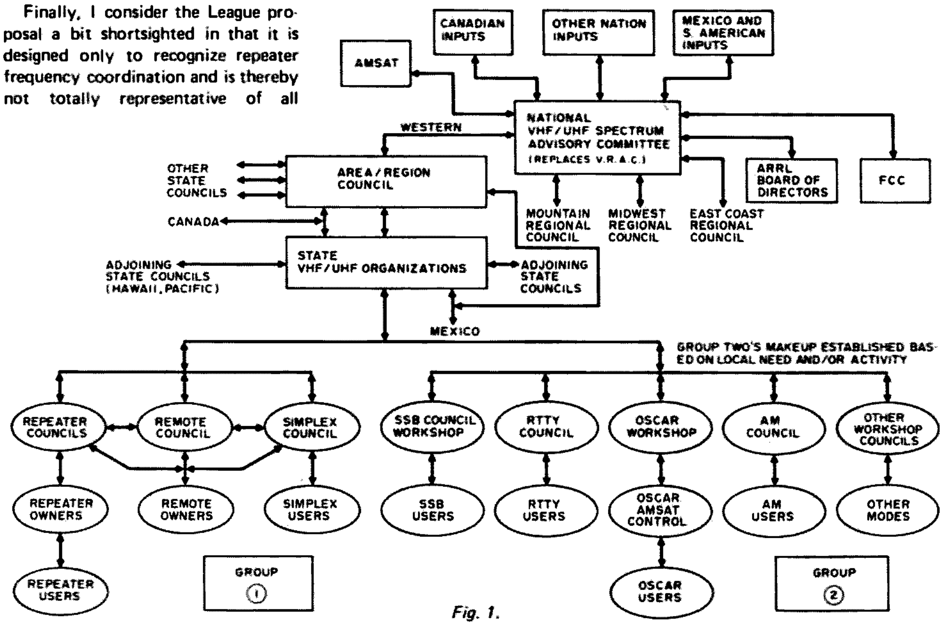

Fig. 1.

opinion on this matter." The forum for his or her specific special interest would be there if he or she had the interest to make their voice heard. That excuse would be gone.

Also of note is that users of a specific mode or band segment would be responsible for solving their own problems unless such problems involved users of a different mode or band segment. If an AM station, let's say, were playing havoc with SSB operations, the two Workshop Councils involved could get together to solve the dilemma. Other interest groups need not get involved, and indeed should not, unless requested to try to help mediate the dispute as a disinterested third party. While total intercommunication would exist between all such groups, no one group would ever become "king of the hill" over the other groups.

Keeping with our example, the logical next step is some form of statewide organization made up of elected representatives of each of the just described local groups. The statewide organization would be comprised of elected representatives of each of the interested local groups, i.e., repeater council, remote owners council, AM users council, etc. Such a group would not get involved in local matters between its members, unless it involved solving a problem that had occurred between two neighboring groups of the same interest. Then only members of groups of similar interest would get involved in any form of the mediation or solution effort. That is to say, should a problem develop between two neighboring RTTY organizations, only members of the statewide council involved in that particular mode and acting as delegates from other RTTY groups would get involved. Repeater council representatives, SSB group representatives, and all other parties would keep hands off unless asked to help mediate the problem. Basically, the statewide organization would only involve itself in matters that were impossible to solve on a purely local level.

Another important responsibility of the statewide organization would be to establish and maintain lines of open communication with adjoining statewide organizations. Since radio signals do not observe "the state line," problems between adjoining states might occur from time to time. It would be the prime responsibility of these statewide organizations to solve such problems on this level. For example, the South Podunk Repeater Association in Texas and the XYZ Repeater Committee in New Mexico both coordinate a repeater to 147.84/.24 at the same time and they happen to be geographically separated by only 50 miles. The way things seem to be today, a repeater war would probably be imminent unless one of the systems were to move. But who is to move? Obviously each repeater would demand its rights and complain bitterly to whoever coordinated it to get that "other machine" off its frequency. With little or no interaction and intercommunication between coordinators, as we have today, a problem such as this would be somewhat insurmountable. But what if there was good communication between neighboring coordination efforts? First, if this were the case, it is doubtful that a problem such as this would ever happen again. A simple exchange of proposed allocation lists and a few telephone calls could solve such a problem before it ever starts.

OK, though, let's pretend (hopefully) that we have such an outstanding problem at the time such a coordination effort is initiated. The first thing would be for the two area coordinating bodies to arrange for representatives of both organizations, along with both system owners, to get together and start talking, rather than hurl brickbats at one another. It is simply amazing what can actually be accomplished when feuding parties learn to communicate rather than hurl insults. On both sides of the continent I have personally seen such happen after all other methods of solving such problems have resulted in a dead end — and I mean all methods! If it were pointed out on a technical level that there was available something as simple as a shift in antenna pattern or a much better channel pair for one of the systems, and that such information was going to be made public to the entire local amateur community (since it was in their best interest to know that machine B would technologically function far better if it was willing to bow to the will of the majority — ah, here we get into peer pressure once more!), then machine B would be hard put to justify its stand on the matter. The same would hold true for machine A if it were deemed that its stand was unreasonable. Again, the entire secret, if it must be deemed such, is for members of the amateur community to learn the art of personal, open-minded, two way communication, and develop lines of interaction from this. Again, though, it should be stipulated that the only people who should be involved in such negotiations are those

Continued on page 78

Children Need Discipline

There has been a good deal of concern expressed by members of the amateur fraternity over many of the Commission's actions in recent times — surprisingly enough, even *deregulation* is being met with resistance and even hostility in some quarters. Much of it is simple inertia, the well-known natural human reluctance to accept change of any kind. And, "We need rules, stiff rules, with teeth — otherwise, the service will become a shambles," is an oft-heard reaction these days.

One also hears the statement, "Children need discipline."

The latter might perhaps be true — for children. The former? Let's look first at some of the Commission's recent deregulatory actions in other services, notably broadcasting, commercial, and even CB.

Broadcast: Inspections of equipment reduced to once weekly instead of the former five days out of seven; deletion of the requirement for station frequency monitors; allowance of 125% positive peak modulation for AM; allowing operators to log meter readings at three-hour intervals, instead of half-hourly. All of this, and more, in recognition of "state of the art." Modern broadcast equipment simply does not need the attention that earlier gear — around which the earlier rules were tailored — required.

Commercial: Deletion of the requirement for annual frequency, modulation and power measurements. This, finally, in recognition of the fact that the majority of two-way shops make these measurements routinely whenever a radio requires servicing — and if a radio is operating satisfactorily, these parameters probably *are* within tolerance.

CB: A general relaxing of a whole set of highly restrictive rules that were almost universally ignored by a vast majority of users. This, along with a reduction in license fee, has resulted in a swing toward more users actually becoming licensed, more use of callsigns on the air, and thus — however infinitesimally — more effective supervision and enforcement. (Ah yes, but what about the "sliders"?)

So now, what of the recent moves deregulating *our* service?

Relaxing of licensing rules for repeaters, particularly with regard to the technical showings, for instance: true recognition of "state of the art," the "art" in this case being the technical excellence of just about every repeater ever put on the air by an amateur group. (To say nothing of the saving of time and paperwork for the Commission itself!)

Logging: No one says you *can't* keep a complete log if you so wish; the new skeleton requirements meet the Commission's needs for enforcement purposes and lighten the recordkeeping burden all around.

Cross-banding: A generally desirable permission, and, so far at least, with little or none of the "cluttering up" of the bands with the indiscriminately dumped signals that many amateurs feared.

And now, the latest proposal: Eliminating of the "portable" and "mobile" designators. It is presumed that we will be allowed to say those words if we wish, and, where necessary for clarification, surely we will continue as we always have. In situations where there's no real need for anyone to know if we're at home or away or rolling or still, we'll be able to save a few words, a few seconds of air time.

Really, from this seat at any rate, we should feel complimented that we are being recognized for the generally well-disciplined, well-motivated group that we know we are, and that our technical prowess is being equated with that of the people in the broadcast and commercial fields. Genuine progress in any human endeavor should never be feared, should indeed be welcomed with open arms. We *are* making progress, and the move toward deregulation certainly seems to be official recognition of the fact.

LETTERS

MUSHIE

Since my father, Sen. Edmund S. Muskie, was not involved in this year's New Hampshire primary, I thought I had heard the last complaint of him being "indecisive, soft, or mushie on the 'issues.' " But then I received my April copy of *73* and noticed that the "issue" was addressed to "S. Mushie." Was it a political comment or just a coincidence that I received it on the day after the February 24 primary? It probably doesn't mean mush to you, but if you correct the mailing label I might consider taking you up on your great $17.76 offer for a three year subscription extension. I am now studying for a ham license after being absent from ham radio for more than ten years. I had a subscription to *73* for several years about 1964 when I was licensed as WN3DCB (Democratic Congressman's Boy) in Washington. The changes in ham radio and in *73* since that time are very exciting. I really enjoy working with and learning about ICs. Good luck — hope to work you some day on CW, Wayne.

Stephen Muskie
Saco ME

NOT TOO BAD

Well, you've done it again. I've just taken my Feb. issue of *73* out of the mailbox, read it from cover to cover, enjoyed every page of it, and got the urge to write to you again!

First of all, on your comment on R.F.I., I own and operate with two friends (both hams) a stereo, CB, and amateur equipment shop. We both sell and service most makes of home entertainment equipment and I must admit that there is nil in any kind of shielding for rf energy. We have found that 98% of all of the inexpensive and expensive stereos, tape players and such have no really good shielding. All of them have open chassis (no bottom plate), wood or plastic cabinets (not even foil around the inside) and I don't think that the manufacturers ever heard of by-pass caps on the ac line! We have found ways to eliminate most cases of R.F.I. from AM/FM and SSB amateur and CB sets; if any of *73*'s readers want some help, have them write me at the shop and I will be glad to pass along some of the information that we have compiled over the past 2 years on elimination or reduction of R.F.I. problems.

Second, on CBers getting into ham radio. Ever since we have opened the shop, I have kept my IC-2F tuned to the 01-61 repeater in New Haven CT. We have quite a lot of activity on the machine, and I like to listen to the local boys rather than the mess on ch. 19. When the local CBers come in for service or just to chat for a while, they always are attracted to the IC-2F. After a demonstration of 2m FM, some interest is kindled, but usually fades after an explanation of how to get a license. This happens quite a bit, but 2 of them showed more interest and asked questions and showed a real interest. To make a long story short, they both passed the test and are now licensed as WA1VVR and WA1VXH. Both are very active on 2m, and are starting to get on RTTY — not too bad for a couple of CBers. I think that if any ham will take the time to show what ham radio is about, get the spark kindled, and help them with the code and theory, most CBers can and do become good ham operators as these two people have shown to us here. Also, we have started classes for the Novice and General class licenses at the store; enrollment now stands at 26, with 19 of them now in CB. I'll keep you posted on their progress, and on the dropout rate (which I think will be high, but you never can tell).

I'm sorry to be so long-winded, but your editorial stirred my mind — which doesn't happen too often. Keep up the good work at *73* and maybe ham radio can benefit from your wisdom.

THE REAL ONE

I have read with great interest the article on a "Startrek Communicator" in the February issue of *73*, because my younger son is a dedicated Trekkie. When I showed him the article, however, he informed me that the described device obviously was an inferior fake. As apparently every true Trekkie knows, the full description of the real Starfleet Communicator, Type 1, including circuit diagram and parts list, is contained in the Starfleet Technical Manual. On Planet Earth this manual (copyright Franz Joseph Designs) is distributed by Ballantine Books, 201 East 50th St., New York NY 10022. The Manual, which is not classified, is apparently available in many bookstores. The circuit diagram is very interesting and I think the designers of ham radio equipment could learn quite a lot from the simplicity and efficiency of this design. After all, to get a range of 12,000 km (7500 miles) with a three-transistor hand-held transceiver on 27.125 MHz during the bad part of the sunspot cycle is not really easy. But maybe it is the Starfleet Communicators which are responsible for some of the funny signals one can hear at around 11 meters (440 inches) if one has a general coverage receiver.

Erich A. Pfeiffer WA6EGY
Granada Hills CA

LET'S GET BACK

I have been a licensed and very active ham for 15 years now and have yet to understand what computers and citizens band radio criticism have to do with the hobby.

Every time I pick up *73 Magazine* from the mailbox, I am hit in the face, directly, from cover to cover, with either massive advertisements for computers (for who knows what) or some outrageously priced two meter rig, which is nothing more than a "legal" CB radio any more.

I am sorry to say that 98% of the articles in the magazine don't even fit the average wealthy amateur, let alone the non-wealthy one.

Don't get me wrong, I am not an "old fogie" on this subject but am simply wondering why the sudden change from an interesting amateur radio publication to a technical manual for sophisticated design engineering of computers, with a little CB humor thrown in to break up the monotony?

I am active on Oscar 6 and 7 so I don't hate VHF in any way other than the way it is used on the FM segment. I can hear the same junk on a single channel CB radio for much less than $250-$300 for a two meter rig.

Let's get back to amateur radio; if I wanted to learn about computers or how high a price I could pay for some cheap transceiver, I would certainly subscribe to a magazine designed for that type of audience.

Gary N. Babcock WA5BMN
Portales NM

GET THE WORD OUT

Have really enjoyed your technical articles, primarily those on I/O. One of your advertisers has a unit for sale, a Univac 769 line printer, and I sure would like to get in touch with these users. I have one and need to find out how to interface it to a computer. Would like to set up sort of a clearing house on applications, parts, etc. If anyone is interested, my phone is 817-292-5211, or you can write:

Jim Beistle WB5BLX
3728 Wilkie Way
Ft. Worth TX 76133

P.S. Hope you can get the word out and keep the good articles going. Who knows? I might even write one someday.

ROY ROGERS' HORSE

I sympathize with all who have had dealings with a certain firm (same name as Roy Rogers' horse) and have run up against a stone wall.

After a four month exercise in futility with the above firm and the famous Miss "D" (if you've talked or have written to her, you know who I'm referring to!), I decided it was time to seek outside help. The route I took was consumer protection and action was swift and satisfactory. I had my money refunded within two weeks after contacting them.

So, if you have a similar problem, get in touch with the Consumer Protection Agency (Chicago directory assistance can give you their address and phone number). They will be most helpful in getting your hard-earned dollar back.

I hope I've been helpful without being too vague and that Wayne will see fit to print this in *73*.

In closing, I'd like to say thanks for a fine magazine. The articles are interesting and informative, the format is great and the magazine is well worth the subscription cost.

Art Krugaluk WN1UUP
Wilmington MA

The letter by WA6EVX/KG6 in the April issue sounded much like my own unhappy dealings with Trigger Electronics. I spare you the details in order to propose several solutions which are all but guaranteed to work. 1. Write one more letter to Trigger. Review the essentials of your transactions specifying original order date, catalogue order number, if possible. Be specific about what you want, goods or refund, or refund only. Ask for the courtesy of a prompt reply. Enclose a copy of your cancelled check, front and back sides, or money order receipt. Put the material in an addressed envelope, but do not seal it! Go to the post office and talk with the postmaster about registered and certified mail, then tell him the whole

story. He will take it from there and you will hear from Trigger pronto. Two friends used this approach and got their merchandise quickly. Federal mail inspectors are bad news to mail order houses.

2. Write a second letter to the Assistant Attorney General, Chief of Consumer Fraud Section, 134 North LaSalle Street, Room 204, Chicago IL 60602. Briefly tell the story of your unsatisfactory dealings with Trigger. Include a copy of your check, and all previous correspondence. Give as complete a picture as possible. If you want help on how to tell your story, the number is 312-641-1988.

3. Send copies of this second letter to the following:

a. Mr. J. Thomas Rosch, Director, Bureau of Consumer Protection, Federal Trade Commission, Washington DC 20580.

b. Trigger's bank: Operations Officer, Oak Park Trust and Savings Bank, Lake, Marion, and Ontario Streets, PO Box 269, Oak Park IL 60301.

c. Better Business Bureau, 430 North Michigan Avenue, Chicago IL 60611.

d. Chamber of Commerce, 948 Lake Street, Oak Park IL 60611.

e. Legal Department, Trigger Electronics. Registered mail, restricted delivery, requires a signature which will be returned to you, providing you a name for a good stiff shot on the phone (their number is 312-771-8616).

It seems proven that appeals by individuals to the company are futile, but collective action by a number of people who have some muscle and punch behind them in the form of federal, state, and local agencies gets results. There is a growing tide of interest in consumer protection and we should both make use of and contribute to it.

Brookings SD

KUDOS

By the way, thanks for having SD Sales as an advertiser. I'm sure you have heard many good things about them, but I would like to add my two cents worth. Their service is great, their prices outstanding, and the quality of their merchandise is hard to beat. I think this is one of the few companies, along with others like VHF Engineering, that *truly* has the amateur at heart.

Ed Picha WB9IMV/9
Urbana IL

After procrastinating for quite a while I had to write and tell you about the service that I recently got from S. D. Sales in Dallas, Tex.

I bought two clock kits complete with xformer and PC board. I put both kits together and found that they ran fast, and also one LED segment was defective in one of the kits. I wrote them about this and PROMPTLY received a reply from them. With the reply I got the necessary parts to correct the problem. What was unusual about this was, unlike some other kit mfrs, S. D. Sales included a schematic as to the placement of the parts, more condensers than were needed, and not just one replacement LED readout, but a complete set of SIX! That is what I call really going out of their way to insure customer satisfaction. By the way, both kits work beautifully.

Frank K. Burnham
Olympia WA

P.S. You've got a great magazine. Keep up the good work.

Let me add my kudos to Bill Godbout Electronics out in California. The clock kit I ordered from him arrived by airmail (cost him $2.75 – how does he make a profit on a $14.50 clock??) less than two weeks after I mailed in the order. He didn't even wait for the cheque to clear. *Now that's service!!*

Keep up the good work at *73* and let's have many more articles on computers.

YASME HISTORY

Our YASME DXpedition operation of 3D2KG is now history. The first QSO was with WA8JUN on 28 Jan 76 and the last QSO was with UA1OB on 23 Feb 76.

A total of some 7500 QSOs were made with amateurs in 113 countries, thus assuring that 3D2KG will eventually qualify for DXCC. Approximately one half of the QSOs were on CW and one half on SSB.

Operation on both phone and CW was held on 10, 15, 20, 40 and 80 meters. Openings into Europe were fantastically good and over 1000 QSOs were had with Europe. It was noted that there was a long path opening to Europe from 0630 to 0830 GMT, followed occasionally by a short path opening from 0900 to 1100 GMT.

Approximately 1000 QSOs were had during the first half of the ARRL Phone DX Competition, which was followed by another 1000 QSOs during the ARRL CW DX Competition. Good openings were had to all parts of the US and Canada on 10 meters during the CW and SSB ARRL contests, but almost no signals were heard on 10 meters during daily checks at other times. Similarly, lots of CW and SSB stations were worked on 80 meters during the contest weekends, but not many at other times.

All continents were worked (WAC) in 28 minutes, 20 Feb 76 on 14mc phone. Stations QSOd were: TU2GA, 0712; I0IJ, 0719; ZP5LX, 0726; JA7SGV, 0729; AH3FF, 0737; and W7TX, 0740 (time in GMT).

The station equipment, the Kenwood Twins and a Heathkit 230 amplifier, worked fine with no failures during a two month period with a grand total of nearly 20,000 QSOs from VR1Z, VR8B and 3D2KG.

It is expected that the next stop will be at Nauru. Please pass this information to all interested persons.

FERMENTING CATALYST?

I remember several years ago when you and *73* were a great help to me back at White Sands (Missile) Proving Grounds and when I used to pick up a copy of *73* for 37¢ at the Yucca newsstand at Alamogordo, N.M. And now again I'm asking for a little assistance in communicating with any of *73*'s readers who might be in the Frankfurt-am-Main, Hanau or Weisbaden areas and are interested in minicomputers (and particularly those who may be planning to build around on 8080 miniprocessor, like I am).

Have just returned two days ago from a three week visit to the States and catching up on copies of *73*. What's this I read about Wayne getting out of BYTE? It won't have the same ole catalyst fermenting.

Will be looking forward in a year or so to be back in the USA and getting my General.

You're right. Done. – Ed.

KEEPING PACE

I read with interest the letter which you printed in your March issue concerning the cardiac pacemaker. Since I am deeply involved with same and have been for over 10 years, I am writing the following information to you:

Cardiac pacemaker, since its first implant over 12 years ago, has gone through quite a revolutionary change. Even up to and including seven years ago, demand type pacemakers could be shut off or reverted to a continuous mode via such imbalance as an electric shaver, ignition coil on a car, television receiver or a microwave oven. The new cardiac pacemakers made by Cordis or any other large manufacturing company are not susceptible to external stimuli.

Recent reports indicate that, because of failsafe circuitry, only by presence near a high power radar transmitter can a demand type pacemaker revert to a continuous mode. A microwave oven will also revert the pacemaker if the patient wearing the device is a midget and can somehow crawl inside.

A magnetic field in the proximity of a demand pacemaker merely alters the function to a continuous mode and does not hinder the patient from receiving the voltage stimuli.

I hope this will help Mr. Hudson and any of your other readers that may have such a device installed.

Joel H. Kornreich K2QBV
President, Cardiotronics, Inc.
Lyndhurst NJ

BICE-ENTENNIAL

Sometimes I disagree with you, but not often. At present you and *73* are tops. I can only see wasted paper in the new size magazine. Larger type and no real advantage of more material.

You may remember that I wrote to you personally because I wasn't getting BYTE. I heard from you that you weren't involved in the mag., so I wrote directly to them and threatened action through the Attorney General of New Hampshire. Well, that produced results immediately. I got the back issues and the current magazines and also a duplicate of the first 4 issues. I would say that they caught up on my subscription at last.

Incidentally, on *73*, I got the April issue yesterday (the 28th of February). Wow, that is really getting ahead of all other magazines.

Now, all I really want is real simple information in an article or somehow that will tell me what I want to know about computers and how they operate and of what use they are going to be to me and why I should build one and so on.

In the March issue I got some of the answers, so I hope you will continue to have articles that will enable poor dummy me to learn and see if I can use and even build a computer.

W7MEU – John Swafford, I believe, a phone co. man and hep on this stuff – is building a computer with the latest micro miniature stuff in it and plans to offer them for sale to the small business man or sell time on his to small business men. How about that?

I finally retired – so I say I am now unemployed. Hah! Don't you believe that, because I am busier than ever. Work that has piled up for years around here – dig this, plant that, paint this, lower this ceiling, make the bathroom modern, and I have enough work for a year steadily and what about ham radio – ugh, not any time except for my Army MARS net. I have a used motor home that needs much work before we can travel and I

won't move it till the work is done. So I bet we don't go anywhere this year. I want a 2m rig synthesized that will reach 148.01 and they just don't make that yet. I did buy a 2m Standard Walkie-Talkie SRC146A the other day – a distress sale. Complete with all the goodies except charger, nicads, carrying case, rubber ducky, crystals, unused, $250. So as soon as Standard gets the crystals here, I will use it for the interim. Oh, will I give some of the guys in parades a shock when I break their (net) parade communications frequency from my Circus Wagon as I traverse the parade route while playing my Calliope. I give a small WAC certificate for all who work me in parades. What? WAC certificate? – Sure, *Worked Al's Calliope*.

I'm removing the 94 simplex cuz it ain't used here. I'm adding another channel that is used more out here. 04-64.

Knowing you are busy, you don't have to answer this letter unless you want to, and I won't be mad. If I ever get over that way, I'll really have to stop by and see if you still have your Brooklyn accent. I'll expect a full VIP tour of your facilities.

I sure marvel at what has been accomplished with the FCC by the talks you and others have had with them in the last year. Keep up the good work.

Oh, yes, as you can see by my stationery I am the top man in the Knights of Pythias in this state for a year, until October. I tell everyone that this is my year, get it – BICE-entennial. I get laughs and groans, but it's fun to spring it on 'em.

I'm a fraternal man by nature, so belong to many – Odd Fellows, Masons, Knights of Pythias and all the side organizations of each group – ladies groups, also. Takes lots of work and evenings. Being a musician, I could play every night of the week because organists and pianists are hard to find for that kind of work, especially ones who actually play so that those doing floor work actually have something to "march to" while traversing the many patterns. Each to his own, I guess.

Keep up the good work with that *73 Magazine* and I hope you finally beat the IRS and the phone co.

Alden N. Bice K7JZT
Seattle WA

Good to hear from you Alden. Watch for better use of the bigger pages, at least in 73. Watch also for a lot more interesting things on microcomputers. Have always enjoyed your calliope QSL card. By all means plan on a visit when up this way . . . still have my Brooklyn accent when needed . . . very handy in New York – Wayne.

LET'S CHANGE

WB4SNC's comments (*Be My Guest*) touch on the subject of foreign fone stations running traffic in the so-called "American" fone band of 14.2-14.35 MHz.

The Managua and Guatemala disasters point up the very real need for Americans to have the right to work foreign voice stations in the 14.1-14.2 MHz portion of the 20 meter band.

Let's change those antiquated regulations to read:

> U.S. Amateur radio stations may utilize the 14.1-14.2 MHz segment of the 20 Meter Amateur band to conduct voice communications with other than U.S. Amateur stations. (NO communications between U.S. stations, except disaster emergency traffic, foreign or domestic.)

The new format, and your efforts to give us more for our money, are greatly appreciated. *73* – a very fine magazine!!!

Virgle H. Meador W4LVZ
Miami FL

PLUG IT IN WHERE?

Since my second hobby is raising sled dogs, I enjoyed the April cover. A question, though: Where do you plug the transceiver in? All in all, I'll bet this eliminates the ignition noise that you complained about a couple of issues ago.

Rich Racicot WA1TIQ
Merrimack NH

DEAR LEW

The American Radio Relay League
Lew McCoy
225 Main St.
Newington CT 06111

Dear Lew McCoy:

At the November meeting of the Michigan Area Repeater Council, your letter was read and discussed. After a lengthy discussion, and although strong FCC support is highly desirable, the MARC voted to go on record as being strongly opposed to the ARRL proposal for these reasons. The ARRL has already amply demonstrated its incapability of providing the national leadership in this frequency coordinating and other fields. These include such failures as the present mess on 450 MHz amateur band planning; failure to promote acceptance of the ARRL 6 meter band plan; the lack of technical and political leadership in providing state of the art information, commercial standards, and political considerations; the failure to have established a national 15 kHz splits policy; failing to promote cooperation between the present repeater councils and such groups as RACES and others. There has been a general failure to promote good operating procedures on VHF. The amateur world has a proud history of self-policing on HF. On HF the ARRL OO program has helped many amateurs. However, this program apparently was never extended to VHF, where it is needed desperately. The ARRL has continually looked down on the Technician class amateur as a fourth rate ham. The only positions available to the Technician in the ARRL organization are almost not worth mentioning. Many Technicians, however, are more technically capable than many higher class amateur licensees. The ARRL should be encouraging manufacturers to upgrade built-for-amateur-use equipment and discouraging such practices as including "94" simplex crystals in VHF FM equipment. The only formal meeting between the FCC and amateur radio operators in the history of the FCC and the ARRL was not even attended by the ARRL. The ARRL should be involved with helping establish national policies and working with local repeater councils. It must be remembered that the ARRL does not represent all us amateur radio operators, and that some amateurs will have nothing to do with the ARRL. The MARC will not be subservient to the ARRL communications department.

We would like this letter published in *QST*.

BEST SYSTEM

Thanks a lot for the 14 wpm tape. Two 20 minute sessions/day for about two weeks got me over the hump. Passed Advanced exam yesterday. ARRL led me astray and cost months of lost time.

I.W.C. Hamlin WN3ZLM
Havre de Grace MD

Just a note to let you know I really enjoy your mag. Also think you have the best system for learning the code. Passed my General on 1/13/76 – haven't seen the ticket, yet. Wonder what the holdup is?

Glenn Waldrum WN5NQW
Sherman TX

P.S. Would like to see more articles from John Murray W1BNN!

FIRST TO MAKE SENSE

Just finished reading the January issue, and in comes the February issue. When am I supposed to find time to read my other magazines? I'm not complaining, just saying wow what an issue. All of the articles were great, but I have to comment on one in particular. That one is "What's All the Noise?" by Mr. Roukas W2DNY.

Now, I've read a lot of articles on noise figure, and this is the first one that made any sense to me. (I have a 1st class FCC license and am not exactly a dumbbell on electronics.) This is the first time I have ever seen anyone write that noise figure was a ratio or measure of the amount of noise a receiver adds to the signal passing through it. Now I have to go back and read all those other articles with this new insight. They all probably said it, but not clearly.

Roger C. Galbraith WA3TCO
Guys Mills PA

A COUPLE OF SUGGESTIONS

I would like to sincerely thank Mr. John Harrington for his most inspiring article in the February, 1976 issue of *73*: "You Can Make Photo PC Boards." This article aroused a long-dormant interest in photography, and helped me make some outstanding (if I do say so myself) PC boards for a local repeater system.

A couple of suggestions might be in order for those who cannot find Naccolith film, as used in the article. I used Kodalith Ortho Film, Type 3, and Kodalith Developers (a two-part solution), quite successfully. This film seems to be quite a bit more easily available than the film called for in the article . . . at least in this part of the country. Naturally, exposure times must be compensated for with this type of film. I have found that an extremely short exposure (½ second) to a No. 2 photoflood is adequate with Kodalith, or, a three second exposure to average room light seems to work just as well. A couple of test runs will quickly determine what works best.

Also, I find that making a paper proof of the negative works beautifully for keeping mistakes off of expensive board stock. I make a paper contact print of the negative using "Velox" film and Dektol developer. The paper proof makes it possible to see any potential problems on the negative . . . any lines that are not crisp and clear, any overexposure of the negative, and any excessive problems with dirt showing up as clear spots on the negative. I use this proof, if all the lines are clear and good, to draw in all the components with a red pen, showing all component leads and clearances, and drawing in all components and jumpers. This stops any problems with one too few component pads, improper component clearances, and wiring errors. Also, this proof makes the final wiring of the completed board much easier.

And, for thoroughly professional-looking boards, Pres-Type or any type of instant press-on lettering can be used to personalize your board. Component points and board terminals can be identified easily using this kind of type, because it will photograph and be etched just like the lines on the

FOUNDATION TO AWARD SCHOLARSHIPS

The Foundation for Amateur Radio, Inc., a non-profit organization with its headquarters in Washington, D.C., announces its intent to award three scholarships for the academic year 1976-77. All amateurs, wherever resident in the U.S. and holding an FCC license of at least General class, can compete for one or more of the awards if they plan a full-time course of studies beyond high school.

The John W. Gore Scholarship pays $750. Applicants must intend to pursue a career in electronics or a related science and have completed at least one year in an accredited college or university toward a baccalaureate or higher degree. Preference will be given to residents of the District of Columbia, Maryland, and Northern Virginia.

The Richard G. Chichester Scholarship also pays $750. Applicants must be members of the ARRL and be sponsored by an ARRL-affiliated club. There is no restriction on the course of study, but applicants must be enrolled in or have been accepted by an accredited university or college and intend to seek a baccalaureate degree. Preference will be given to residents of Ohio, Kentucky, Indiana, Illinois, the District of Columbia, Maryland, and Northern Virginia.

The Edwin S. Van Deusen Scholarship pays $250. Applicants must have been accepted or enrolled in an accredited 2 year technical school and intend to seek an Associate degree in a science-related area. Area preference is the same as the Gore Scholarship.

Application forms can be requested from the Chairman, Scholarship Committee, 8101 Hampden Lane, Bethesda, Maryland 20014. Requests must be postmarked prior to June 1, 1976.

The Foundation is devoted exclusively to promoting the interest of amateur radio and to scientific, literary and educational pursuits that advance the purposes of amateur radio.

* = described in last issue

SOWP BICENTENNIAL CW QSO PARTY

The first weekend in June 1976 has been set aside by the Society of Wireless Pioneers (SOWP) for their Bicentennial CW QSO Party. The activity will start at 1200 hours GMT on Saturday June 5th and end at 2400 hours GMT on Sunday, June 6th. Suggested frequencies for the event are 55 kHz up from the low end of each band. Members with Novice licenses should use the mid-frequency of each Novice band. The call will be CQ-SOWP.

Stations will exchange signal report, QTH (city and state) and SOWP membership numbers. A special certificate will be awarded to all member stations who contact 10 or more fellow members. Stations desiring a certificate should submit a list of contacts made – showing callsign and SOWP membership number of the station worked. Submissions should be made not later than June 15, 1976 and should be mailed to: Bill Willmot K4JPF, V.P.-P.R., 1630 Venus Street, Merritt Island FL 32952.

BITING BUG AWARD

A plaque and $50 prize are being offered to the writer of the best article about ham radio published in an American non-ham radio publication during 1976. Articles will be judged on how well they attract non-hams to ham radio, based on subject matter, style, accuracy, illustrations, and mention of where a reader may obtain more information about ham radio. The type of publication and circulation will also be considered, with youth magazines being judged higher.

All entries must be submitted by January 31, 1977 to: Ray Collins WA2GBC, Harter Road, Morristown NJ 07960. Send a photostat of the article along with the name and date of the publication.

SPESM BICENTENNIAL CERTIFICATE

The Society for the Preservation and Encouragement of Six Meters is offering a Bicentennial Certificate for working any 5 members between January 1, 1976 and December 31, 1976 on 50 to 54 MHz any mode. Send date, time, call letters, and SPESM Membership Number along with a check or money order payable to Dan Atwell, for $1.25 to cover printing and postage costs. Send application to: The SPESM Club, Bicentennial Committee, P.O. Box 768, South Elgin IL 60177.

WORKED RAAG MEMBERS AWARD

The award is issued by the Radio Amateur Association of Greece for contacting members after January 1973 as follows: Class 3 – DX stations work 15 SV RAAG members, EU stations work 50 SV RAAG members; Class 2 – DX stations work 30 SV RAAG members, EU stations work 75 SV RAAG members; Class 1 – DX stations work 50 SV RAAG members, EU stations work 100 SV RAAG members.

ATHENS CITY AWARD

This award is given for contacting stations resident in the city of Athens, GREECE after January 1973 as follows: Class 3 – DX stations work 10 SV stations in Athens, EU stations work 20 SV stations in Athens; Class 2 – DX stations work 20 SV stations in Athens, EU stations work 30 SV stations in Athens; Class 1 – DX stations work 30 SV stations in Athens, EU stations work 50 SV stations in Athens.

For either award: No restrictions on band or mode and club station SV1SV counts as 3 for DX or 5 for EU in all classes. QSLs are not required to be sent. Send application showing log copy certified by two other hams or a club official and 12 IRCs or $2 to award manager, SV1IG, Anastasios Panos, P.O. Box 564, Athens, GREECE.

CAIRNS CENTENARY AWARD

All stations outside of the Cairns, Australia area are eligible for the award (outside 100 mile radius of Cairns). VK and ZL stations must QSO with 3 Cairns area stations while overseas stations need only QSO with 2 Cairns area stations. Send a copy of log details to CARC, VK4HM, P.O. Box 1426, Cairns, 4870 QLD AUSTRALIA.

Awards will be forwarded in bulk via bureaus unless the cost of postage and packing is remitted. The award will be available for the entire 1976 year. The following list shows the Cairns area stations – VK4s: TL, MH, SU, ZCS, YG, AMO, NF, ZBU, AE, NU, ZY, ZNZ, RY, HK, YT, ZIP, HM, VI, CI, ZIB, KV, VT, OX, NI, DJ, DB.

27th ANNUAL ARMED FORCES DAY COMMUNICATIONS TESTS

Starts: 1300 GMT Saturday, May 15
Ends: 0245 GMT Monday, May 16

This year's observance of Armed

Forces Day marks the 27th anniversary of an annual event reflecting the long-standing good relations between the amateur radio fraternity and our military radio stations. These tests give amateur operators their yearly opportunity to demonstrate superior technical skills and receive proper recognition for their proven expertise. The proceedings include crossband operations in CW, SSB, and RTTY receiving tests. Special commemorative QSLs will be awarded to amateurs achieving a verified 2-way contact with any of the participating military stations. Special certificates also will be sent to amateurs who receive and accurately copy the Armed Forces Day message from the Secretary of Defense, as transmitted in both CW and RTTY during the receiving tests.

The military stations WAR, NAM, NPG, and AIR will transmit on military frequencies and listen for amateurs transmitting in those portions of the amateur bands indicated on page 130. The operators at the military stations will specify that portion of the amateur sub-band they are tuning.

CW RECEIVING TEST:

Receiving test will be conducted at 25 wpm, broadcast will be a special Armed Forces Day message from the Secretary of Defense to all participants. A ten minute CQ call for tuning purposes will begin at 0300 GMT May 16th. The message will be transmitted precisely at 0310 GMT from the following stations:

WAR – 4030, 6997.5, 14405; NAM – 4012.5, 7385, 14386; NPG – 4005, 6989, 14375, 49.995 MHz and 143.995 MHz; AIR – 7315, 13997.5.

RTTY RECEIVING TEST:

The RTTY test will be transmitted at 60 wpm. A ten minute CQ call for tuning will begin at 0335 GMT May 16th with the message beginning at 0345 GMT. Transmission will be from the following stations:

WAR – 4030, 6997.5, 14405; NAM – 4012.5, 7385, 14385; NPG – 4010, 7347.5, 13922.5, 148.410 MHz; AIR – 7315, 13997.5.

SUBMISSION OF TEST ENTRIES:

Transcripts should be submitted "as received" with no attempt to correct possible transmission errors. Indicate on the page containing the test: time, frequency, callsign of station copied, your name, call (if any), and address. Entries should be postmarked no later than 25 May 1976 and submitted to the respective service copied.

Stations copying NAM and NPG should send entries to: Armed Forces Day Test, Chief, Navy-Marine Corps MARS, Building 17, 8th Street & South Courthouse Road, Arlington VA 22204.

Stations copying WAR should send entries to: Armed Forces Day Test, Commander, United States Army, Communications Command, ATTN: CC-OPS-OM, Fort Huachuca AZ 85613.

Stations copying AIR should send entries to: Armed Forces Day Test, Air Force Communications, Service/DOYF, Richard Gebaur Air Force Base MO 64030.

NEW YORK STATE QSO PARTY

Contest Periods:
1600 GMT May 22 to
0400 GMT May 23
1200 to 2359 GMT
May 23

Stations may be contacted once on each mode (phone and CW) on each band. NY stations may work other NY stations. Mobiles and portables changing county may be reworked by out of state stations.

EXCHANGE:

RS(T), serial number starting at 001, and QTH – county for NY stations; state, province, or country for others.

FREQUENCIES:

CW – 1810, 3560, 7060, 14060, 21060, 28060. Phone – 3975, 7275, 14285, 21375, 28575. Novice – 3725, 7125, 21125, 28125.

SCORING:

Score one point per QSO. NY stations multiply QSO points by the total number of states, provinces, and countries. Non-NY stations, multiply QSO points times number of different NY counties worked (62 max).

ENTRIES:

Number the first contact for each new multiplier in logs. A check sheet is requested from stations working over 100 contacts. Entries should be sent no later than June 30 to: John C. Yodis WA2EAH, 43 Beacon Avenue, Albany NY 12203. Results will be sent only to those enclosing a large SASE. Appropriate certificates will be issued.

SPRING NOSTALGIA RADIO EXCHANGE

Starts: 1800 GMT Sunday,
May 23
Ends: 0100 GMT Monday,
May 24

Sponsored by the Southeast Amateur Radio Club K8EMY of Cleveland, Ohio, the contest is open to all amateurs. The object is to restore, operate, and enjoy older equipment with like-minded hams. A Nostalgia Radio is any equipment built since 1945 but at least 10 years old – an advantage, but not required in the exchange. The same station may be worked on each mode on each band, but no AM phone below 21 MHz. General call on CW is "CQ NX," on phone "CQ EXCHANGE." Noncontestants may also be worked.

FREQUENCIES:

CW – 70 kHz up from low band edges. Phone – 3910, 7280, 14280, 21380, 28580. Novice – 3720, 7120, 21120, 28120.

EXCHANGE:

Name, RS(T), state-province-country, transmitter type (home brew send P.A. tube, i.e., "807"), and other interesting pleasantries.

SCORING:

Add the numbers of different transmitters, states-provinces-countries for each band. Multiply by the total number of QSOs; non-contestants' QSOs count one, NX QSOs count three. Multiply that total by Nostalgia Multiplier: total years old of your transmitter and receiver (if transceiver, multiply years old by 2). Different equipment combinations may be used; in that case figure scores separately for each and combine for total score.

AWARDS:

Certificates are not awarded for highest scores, rather for unusual and ingenious experiences, circumstances, achievements, etc.

ENTRIES:

Send logs, comments, pictures, anecdotes, etc., to W8KAJ, 2386 Queenston Road, Cleveland Heights OH 44118.

NOTE: There was a small response to the first Exchange last December, so the Exchanges will be held on a three times a year basis. Why not try this "FUN" contest and make some new friends!

IARS/CHC/FHC/HTH QSO PARTY

Starts: 2300 GMT Friday,
June 4
Ends: 0000 GMT Monday,
June 7

An SASE to K6BX will bring detailed information. Contest is open to all amateurs and SWLs worldwide. Same station may be worked on each band and mode, SSB and AM are different modes.

EXCHANGE:

QSO number, RS(T), name, CHC/FHC number, US state and county or similar division. Nonmembers send HTH instead of CHC/FHC number.

SCORING:

CHCers – score 1 point per QSO with other CHCers, 2 points per QSO with HTHers; 1 additional point if YL, B/P, FHC, Novice, CHC-200, Merit or Club station, or if on VHF/UHF; double above points if QSO is outside own country.

HTHers – contacts with other HTHers count 1 point, with CHCers count 3 points. Rest same as above.

SWLs – use above depending on whether CHC member or not.

MULTIPLIERS:

Each different continent, country, ITU zone, and US state counted only once.

FINAL SCORE:

Multiplier times total QSO points is final score. Multi-operator stations divide score by number of operators.

FREQUENCIES: (for US and DX as allowed)

CW – 3575, 3710, 7070, 7125, 14075, 21075, 21090, 21140, 28090, 28125.

Phone: 3770, 3775, 3790, 3943, 3960, 7070, 7090, 7210, 7260, 7275, 14320, 14340, 21360, 21440, 28620.

AWARDS:

Hundreds of certificates and trophies in all categories and divisions are awarded. An SASE will bring further information from K6BX. Send all requests and logs to: International Amateur Radio Society, K6BX, P.O. Box 385, Bonita CA 92002. Logs should be mailed within 15 days after the close of the QSO Party.

MINNESOTA QSO PARTY

Starts: 0001 GMT, Saturday
June 5
Ends: 0500 GMT, Sunday
June 6

Sponsored by the Heartland Amateur Radio Club with a possible special events call station (call unknown at this time). No restrictions as to mode or operating time; use 160 to

Continued on page 130

RESULTS

RESULTS OF 5th ANNUAL SARTG WORLDWIDE RTTY CONTEST

Single Operator, top ten world scores:

Class A, up to 100 Watts		Class B, over 100 Watts	
I6VGA	133,955	I1PYS	229,320
F6ALL	85,760	CT1EQ	204,590
PAØORZ	49,060	I1AA	204,000
WØYDJ/4	36,960	OD5HC	167,750
LA7AJ	23,230	HB9AVK	147,600
G3RDG	19,080	ON5WG	121,980
SL5AR	16,975	W3EKT	114,725
LA2IJ	13,230	WA3JTC/ZP	113,425
OK2BJT	9,240	4X4MR	107,250
OK1MP	7,705	SMØOS	96,815

Special classes – top five scores:

Class C, multi-operator		Class D, SWLs	
DLØTD	239,370	Wolfgang Geller	154,000
HA5BKM	98,890	I3-13018	100,160
OZ7RD	44,800	I3-14258	93,130
OK1KSL	41,065	I4-14707	58,575
HAØKDA	22,880	JA1-3477	1,750

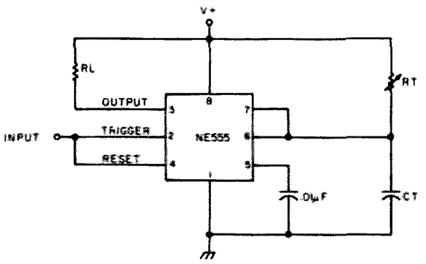

Fig. 1. Basic timer circuit. The time delay is determined by the component values of R_t and C_t and may be calculated from the equation: $t(sec.) = 1.1\ R_t\ (Ohms) \times C_t\ (farads)$. The timing diagram for this circuit is shown in Fig. 2.

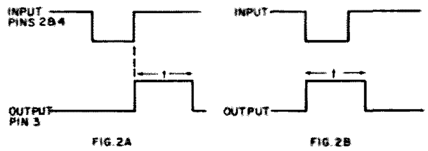

Fig. 2. Fig. 2(a) shows the timing diagram for the basic timer circuit of Fig. 1. Fig. 2(b) shows the timing diagram that would result if the reset terminal were tied to V+ rather than to the input terminal.

Super COR

--digital ... of course!

Waukee IA 50263

One of the auxiliary circuits essential to the operation of a repeater is a COR, or carrier operated relay. To date, a number of COR circuits have been designed, utilizing a variety of active devices (tubes, transistors, op amps, UJTs, etc.) to provide a number of auxiliary repeater control functions. However, few of the previously presented designs have been truly complete. Some designs presented timing circuits and auxiliary repeater control circuits but avoided the rather sticky task of interfacing the logic circuits with the high impedance circuitry of the still popular commercial tube-type FM receiver. Other designs detailed elaborate circuitry for impedance matching to the receiver, but ignored the auxiliary circuits necessary for the convenient, practical operation of a repeater. Still other designs employed timers and auxiliary circuits of dubious stability.

The digital COR described in this article employs state of the art solid state devices, allowing simple and compact construction, as well as providing stable, reliable and convenient repeater operation. The input circuit is specifically designed to interface with commercial tube-type FM receivers.

The versatility of the digital COR is best described by detailing the functions it was designed to perform:

1) The most basic function of keying the repeater transmitter upon detection of a carrier on the repeater input frequency.

2) A squelch tail timer – this timer provides a delay between the time the reception of carrier ceases and the time the repeater transmitter drops out, a necessary feature for consistent copy of mobile stations in fringe areas.

3) A three minute timer that will "lock out" the repeater transmitter should there be a continuous carrier of longer than a three minute duration detected by the repeater receiver.

4) A means of resetting the three minute timer without letting the repeater transmitter drop out. Many of the previously designed CORs have provided for resetting of the three minute timer only upon dropout of the transmitter, necessitating an annoying squelch tail burst at the end of each transmission, and causing unnecessary wear and tear on the COR relay. In addition to providing a means for resetting the three minute timer a fraction of the way through the squelch tail time delay period, the digital COR also provides a means for an audible indication when this has been accomplished. A DPDT center-off switch has also been included with which two other modes of resetting the three minute timer may be selected.

5) A means of keying or disabling the repeater transmitter via a remote contact or digital logic signal applied to the COR. This feature has been included to make the COR compatible with remote control devices, monitor receivers, code and voice identifiers, etc.

Circuit Building Blocks

One of the basic building blocks of the digital COR is the NE555 timer IC. Since this IC has been described in numerous articles in past issues, only the most salient characteristics will be repeated here. The reader who desires additional information is urged to consult the references listed at the end of the article.

Fig. 1 shows the external component connections of

the basic timing circuit. The timing diagram for this connection is shown in Fig. 2(a). With the reset terminal connected to the trigger terminal, the timing cycle is initiated on the trailing edge of the input pulse. The output, pin 3, remains at a logic "1" voltage during the timing cycle, the duration of which is determined by the values of R_t and C_t.

As depicted in the timing diagram of Fig. 2(b), the timing cycle would begin on the leading edge of the input pulse if the reset terminal were connected to V+ rather than to the trigger terminal.

Fig. 3 shows how an NPN transistor can be added to the basic circuit to provide an auxiliary reset feature. A positive voltage applied to the auxiliary reset input will cause C_t to remain discharged, and prevents completion of the timing cycle.

The timing diagram for this circuit is shown in Fig. 4. Note that the output switches to a logic "1" voltage at time (1), the trailing edge of the input pulse. However, the timing cycle does not actually commence until the auxiliary reset input returns to a logic "0" at time (2). The output then returns to a logic "0" t seconds later as determined by the values of C_t and R_t.

The other IC employed in the digital COR circuitry is the SN7400 quad NAND gate. For those not familiar with logic circuitry, Fig. 5(a) shows the commonly used symbol for the two input NAND gate. Fig. 5(b) shows the truth table that governs its logic output.

One final circuit building block is necessary to build the digital COR. This is the circuitry that provides a digital "on" or "off" signal to the logic circuits depending on the presence or absence of a carrier on the repeater input frequency. This is accomplished by the circuit shown in Fig. 6.

Q1, an N-channel JFET, provides impedance matching between the high impedance of the receiver and the considerably lower impedance of the logic and timer circuits of the COR. Q2 and Q3 comprise the analog to digital portion of the circuit, providing either a logic "1" or "0" voltage at the collector of Q3 depending upon the magnitude of the analog signal at the drain of Q1.

A negative going voltage in the receiver during reception of carrier will cause a corresponding increase in the drain voltage of Q1. The magnitude of the drain voltage sufficient to cause the collector of Q3 to switch from a logic "1" to a logic "0" is determined by the setting of the 5k Ohm trimmer.

Note that the collector and emitter of Q2 are reversed from the conventional biasing arrangement in order to provide a sharper switching characteristic.

Composite Circuit Description

We can now proceed with how the building blocks just described can be utilized in the design of the digital COR. Fig. 7 shows the simplified logic diagram of the composite circuit. For the sake of clarity, some timing components, bypass and coupling capacitors, and input circuitry have been omitted from this diagram. The timing diagram for a typical transmission cycle is depicted in Fig. 8.

Referring to Figs. 7 and 8, the receiver detects a carrier

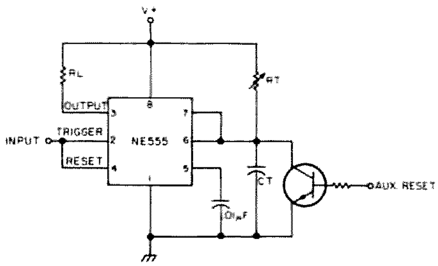

Fig. 3. The addition of an NPN transistor and resistor provides an auxiliary reset feature. The timing diagram for this circuit is shown in Fig. 4.

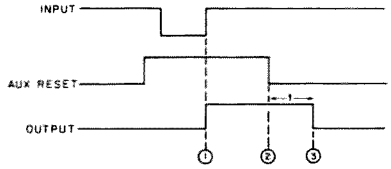

Fig. 4. Timing diagram for Fig. 3.

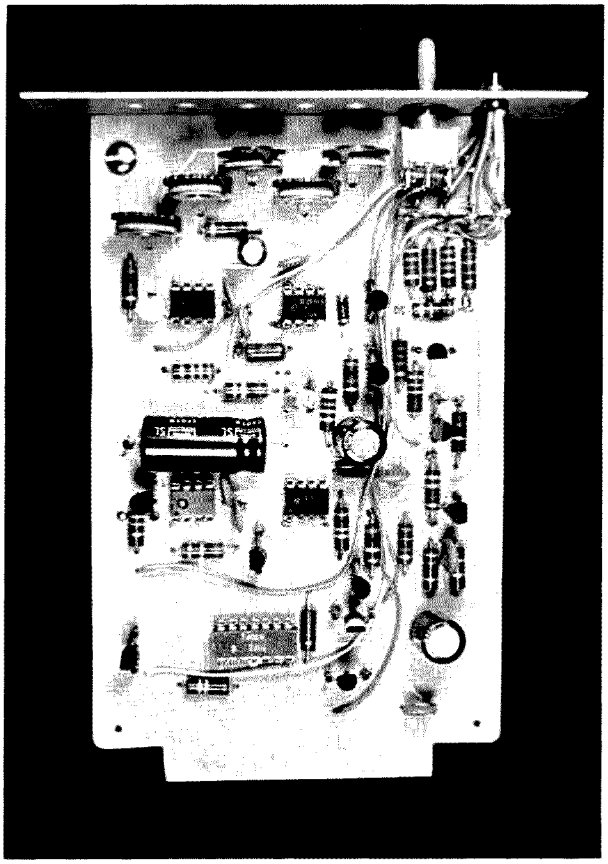

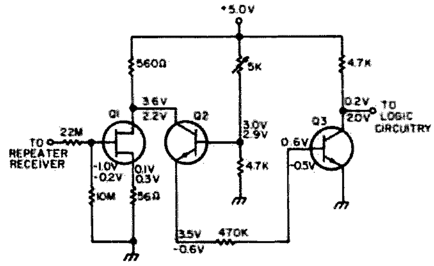

Fig. 6. Input matching and analog to digital portion of the digital COR. Top voltages are voltages during carrier reception conditions. The bottom voltages are taken during quiescent conditions. All voltage measurements are taken with a high impedance voltmeter.

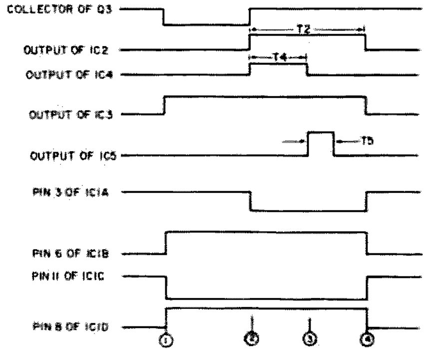

Fig. 8. Timing diagram for a typical transmission cycle, using the logic circuit shown in Fig. 7.

on the input frequency at time (1), driving the collector of Q3 to a logic "0" voltage. Remembering the truth table for a NAND gate shown in Fig. 5(b), the "0" on pin 5 of IC1B drives pin 6 of IC1B to a logic "1." This removes the "0" from the reset terminal of the three minute timer, IC3, allowing its output to go to logic "1," and initiating its timing cycle. With both pins 12 and 13 of IC1C at logic "1," pin 11 is driven to a logic "0." Section IC1D of the quad NAND gate simply inverts the output of section IC1C, providing a positive keying voltage to the transmitter keying relay or keying circuit.

At time (2) the carrier ceases, allowing the collector of Q3 to return to a logic "1" voltage. This removes the "0" from the reset terminals of both IC2 and IC4, allowing their timing cycles to commence. The outputs of both IC2 and IC4 are driven to the logic "1" state during their timing cycle. IC1A inverts the output of IC2, providing a logic "0" at pin 4 of IC1B. Thus pin 6 remains at a logic "1" and the transmitter remains keyed.

At time (3) timer IC4 times out and its output switches to a logic "0," keying timer IC5. The output of IC5 is a brief positive pulse of sufficient duration to discharge the timing capacitor of the three minute timer, IC3, reinitializing its timing cycle. The output of IC5 can also be used to provide a tone burst for audible indication that the three minute timer has been reset.

At this point in the transmission cycle the QSO could continue, the intervals between each of the subsequent transmissions needing only to be t_4 seconds long (as determined by the timing components of IC4) in order to be assured that the three minute timer is being reset. The transmitter need never drop out during this time.

At time (4) the squelch tail timer, IC2, completes its timing cycle and its output returns to a logic "0." Pin 3 of IC1A is driven to a logic "1." The resulting "0" at pin 6 of IC1B forces pin 11 of IC1C to a logic "1." IC1D inverts this input and the transmitter drops out.

Note that if a carrier is present continuously for any length of time greater than three minutes, or if during a QSO of longer than three minutes there is no interval of t_4 seconds or greater between adjacent transmissions, the three minute timer will time out. Pin 12 of IC1C would be driven to logic "0." Pin 11 would then go to a logic "1," and the transmitter would drop out.

D1 and D2 provide the remote keying and shutoff functions respectively. The COR will respond the same to a logic "0" remote keying signal on the cathode of D1 as it does to a local keying signal present on the collector of Q3. A "0" applied to the cathode of D2 will prevent the transmitter from being keyed, regardless of the status of the timer outputs or the local or remote keying voltages.

The actual schematic is presented in Fig. 9. Three light emitting diodes have been included for visual indication of circuit operation. The green LED indicates that a carrier or remote keying signal is being received. The red LED indicates that the transmitter

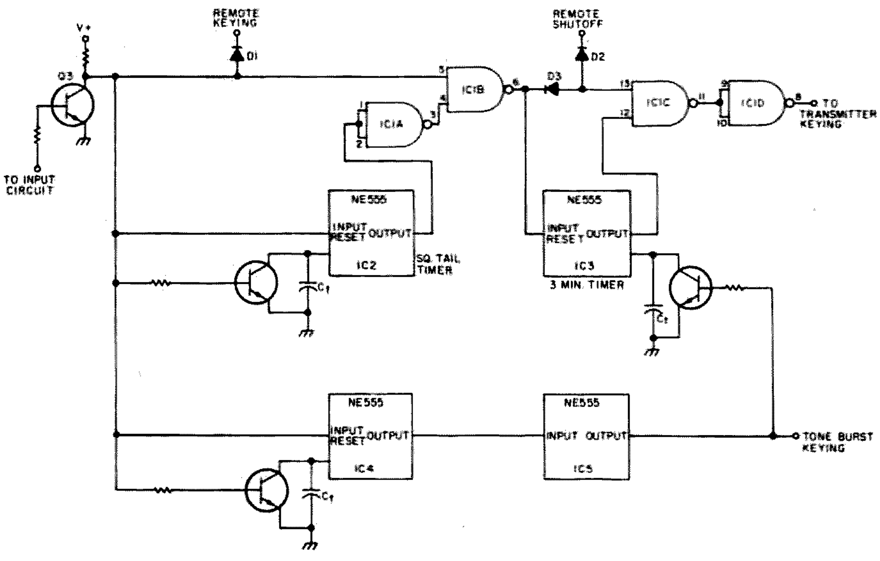

Fig. 7. A simplified composite logic diagram of the digital COR.

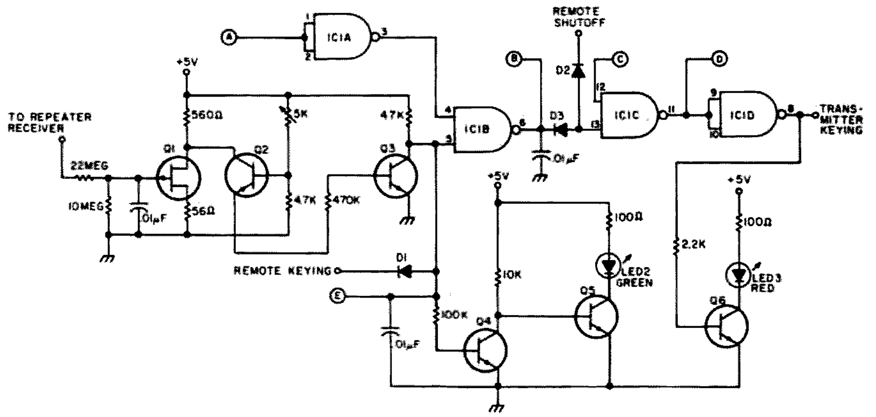

Fig. 9(a). Input and gating circuit for the digital COR. Encircled letters refer to connections to the time delay circuit of Fig. 9(b).

is being keyed, and the yellow LED will flash for the brief intervals when IC5 applies a reset pulse to the timing capacitor of the three minute timer, IC3.

The mode of COR operation may be selected by the position of SW1, a DPDT, center-off, switch. In the center-off position, the three minute timer will not reset until the transmitter drops out. In position 1 (the position of the switch in Fig. 9(b)), the three minute timer will reset the instant that the repeater receiver detects the absence of a carrier signal. In position 3, the three minute timer will be reset by a pulse from IC5, as described in the previous discussion of circuit operation.

Construction

The circuit board patterns for the digital COR are shown in Figs. 10 and 11. Due to the number of components in the circuit, a double sided circuit board was deemed a necessity to avoid the proliferation of wire jumpers that would have been required with a single sided board. The circuit board is designed to fit into a standard 15-pin PC board edge connector, though this could easily be modified for different connector arrangements.

Construction should be straightforward if the components are mounted as shown in Fig. 11. Bearing in mind that the circuit board is double sided, the components that must be soldered to both sides of the board should be mounted first. The remainder of the components can be mounted in any order.

There are no substitutes for the five ICs listed in the parts list. Fortunately, they are inexpensive, costing approximately five dollars for the lot.

The experienced builder is, however, encouraged to substitute bargain priced transistors for the HEP transistors listed in the parts list. Though the HEP devices will work with absolutely no problem, a substantial savings can be realized with a trial and error substitution of less expensive semiconductors.

The COR board should be mounted in a shielded enclosure. The connection of the repeater receiver to the input of the COR should be made with a shielded cable, since any rf or electrical noise introduced into the input circuit will result in erratic circuit operation. All other external wiring to the COR should be as short as possible, adequately bypassed at both ends, and shielded if the length is appreciable.

Checkout and Calibration

The calibration procedure is not at all difficult. A well regulated five volt power supply, a voltmeter, and a watch or clock with a second hand are essential. A calibrated signal generator would be convenient for the final adjustment but is not absolutely necessary.

First connect the power supply to the appropriate terminals as indicated in Fig. 11. The reception of carrier may be simulated by grounding the remote keying input with a jumper. With the aid of the watch or clock and the LED indicators, it is then possible to set the timing intervals of the four IC timers.

The final adjustment is that of the 5k Ohm trimmer in the input circuit. First, find a point in the receiver squelch circuit that switches from a slightly negative voltage during quiescent conditions to an even more negative voltage during the reception of carrier. In almost all of the tube-type

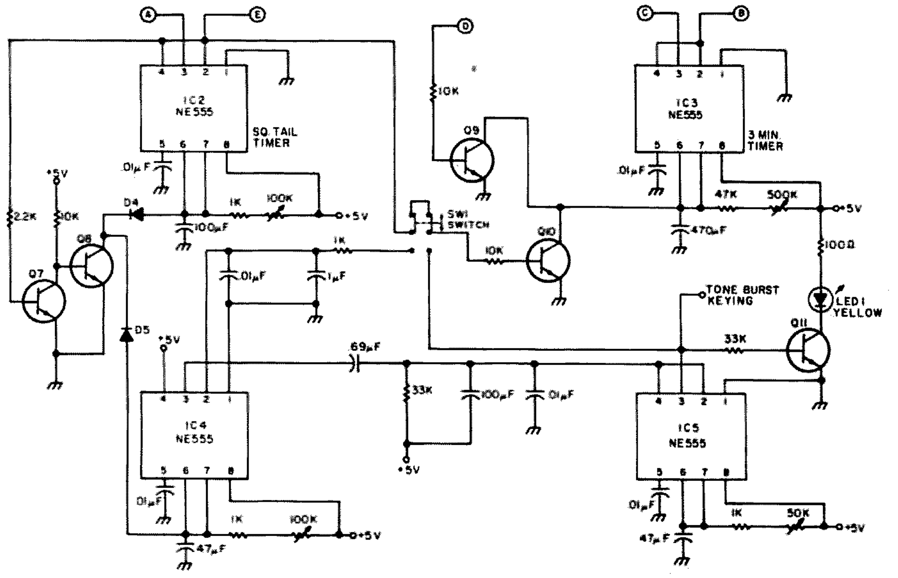

Fig. 9(b). Timing circuit for the digital COR. Encircled letters refer to connections to the input and gating circuit of Fig. 9(a).

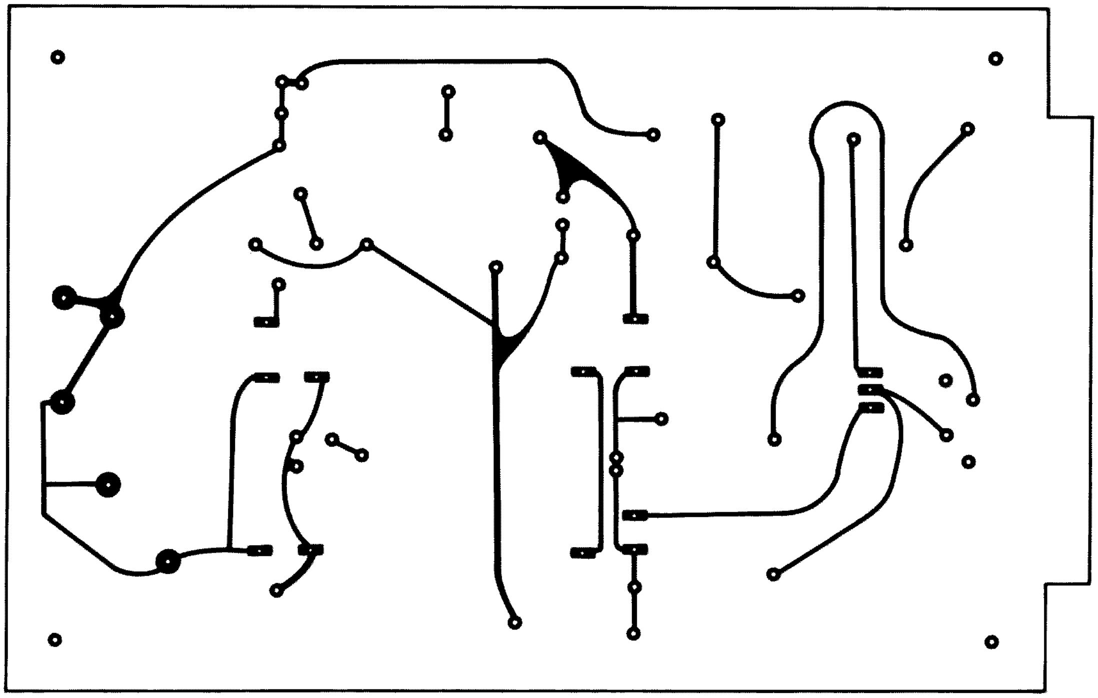

Fig. 10. Component side of PC board. The holes in the four corners should be used for pattern alignment during PC board etching.

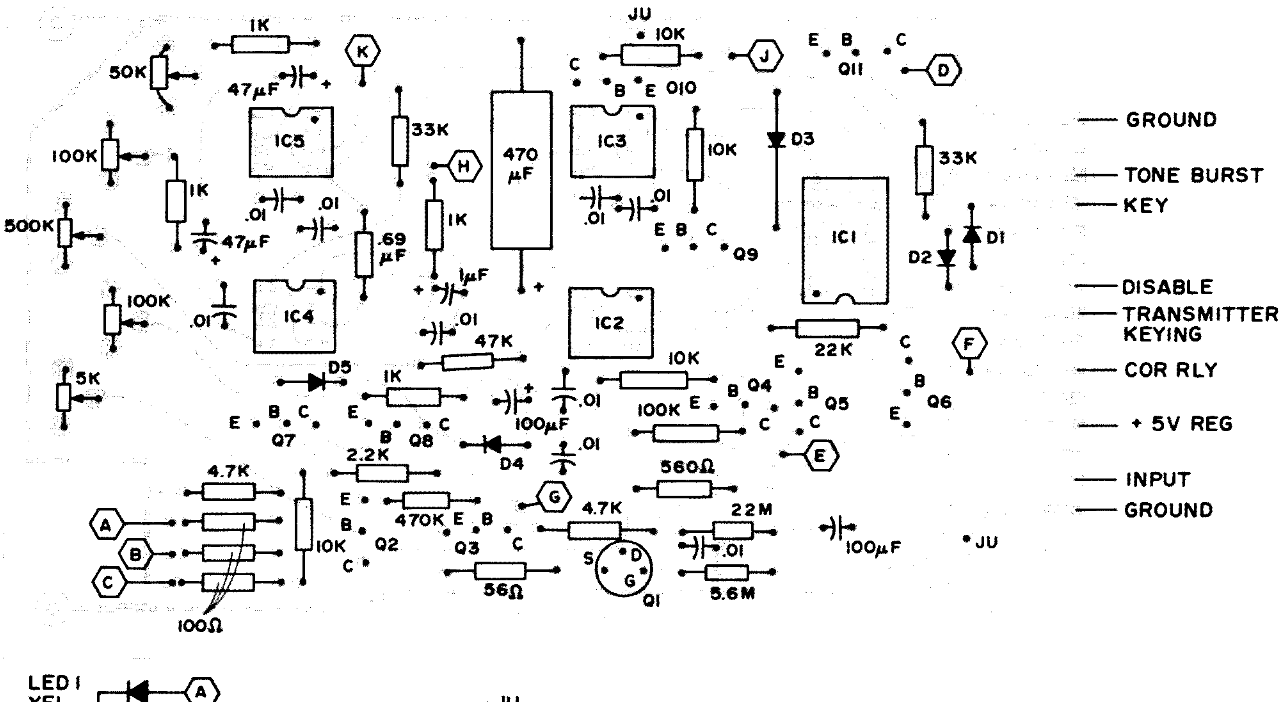

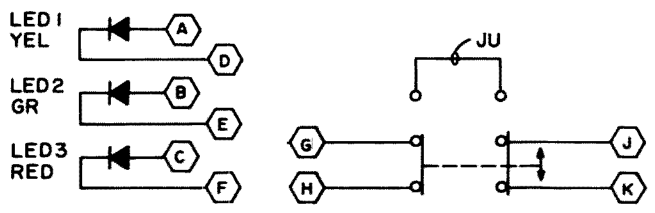

Fig. 11. Mounting diagram for the digital COR components. Note that this is a bottom view of the PC board. A wire pin must be soldered to both sides of the PC board at points marked "JU." External connections to the LED indicators and the switch SW1 are also shown.

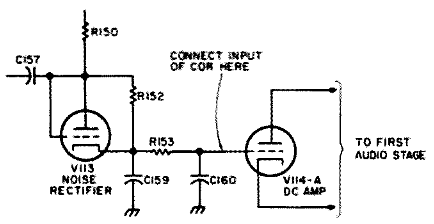

Fig. 12. Connection of the input of the digital COR to the squelch circuit of the repeater receiver. The circuit shown is a portion from a Motorola G-strip receiver. The connection point will be similar in other types of tube receivers.

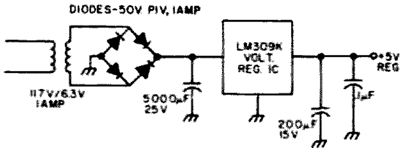

Fig. 13. Simple 5 volt regulated power supply.

commercial FM receivers the grid of the first stage following the noise rectifier has this characteristic. A simplified sketch of the squelch circuit of a typical tube-type receiver and the correct point of connection to the COR are shown in Fig. 12.

Once the shielded cable connection to the proper point in the receiver is made, determine if the squelch control threshold setting has been significantly altered. If so, the 10 and 22 megohm resistors must be substituted with ones of higher resistance. Some experimentation may be required to find the correct resistance values to match a particular receiver.

Next, inject a carrier signal into the receiver and adjust the 5k Ohm trimmer in the COR input circuit until the green LED lights at the desired level of receiver quieting. If consistent operation of the input circuit cannot be obtained for any setting of the trimmer, the ratio of the two input resistors will have to be varied, remembering not to let their sum be less than the value that will leave the squelch threshold setting unaffected. The voltage at the gate of Q1 compared with the typical gate voltage noted on Fig. 6 should be used to determine which way the ratio must be altered. The value of the resistor between the gate and ground must be increased if the amplitude of the gate voltage is significantly less negative than -1.0 volts during carrier reception. Conversely, this resistor must be decreased if the negative excursions of the gate voltage are significantly more negative than -1.0 volts.

If a signal generator is not available, the input adjustment may be made by varying the squelch control to simulate carrier reception. Opening the squelch control until audio noise is heard roughly corresponds to the reception of carrier, thus causing the input circuit to switch "on" when the 5k Ohm trimmer has been suitably adjusted.

In all cases of difficulty, the typical voltages given in Fig. 6 should be used to help diagnose the problem.

This completes the settings and adjustments of the COR.

Optional Circuits

As was previously mentioned, the digital COR requires a well regulated five volt power supply. For those who don't have a personal preference, the circuit of Fig. 13 is suggested as the simplest and probably the cheapest available.

The digital COR was originally designed to control a solid state switch that did the actual transmitter keying. For those who prefer to use a relay to switch on the transmitter, the circuit of Fig. 14 is offered. The diode should be attached directly across the relay coil to prevent inductive transients from damaging the semiconductors.

Finally, Fig. 15 shows a simple tone burst circuit that can be used for an audible indication that the three minute timer has been reset.

Conclusion

The digital COR described in this article has been used successfully with both G.E. Progress Line receiver strips and Motorola Sensicon G-strip receivers. The COR is currently in use on the WRØAGZ repeater in Sioux City, Iowa. ■

EDITORIAL BY WAYNE GREEN

from page 4

in very small type so as to get the most material I could on each page. Older readers can be thankful that I, too, have one foot in the grave.

Eventually I managed to put my foot down (the other foot) and get things going the way I wanted them ... some day I'll tell you the inside story of how I managed to lose BYTE and all that mess ... suffice it to say the motto I have above my desk applies very well to me ... "Intelligence is no impediment to stupidity." Anyway, we will be running four columns in *73* most of the time for a while. There will be a few three column articles, using up type already set. See how you like it ... compare it, if you get a chance, with the layouts in *CQ* ... if you can find a copy anywhere. They are using giant type, two columns, apparently because they have too little material to fill their pages. In this way they seem to have merely enlarged the old two column pages to the new size. *Ham Radio* has done about the same ... very large type, lots of blank white page ... so it takes very little material to fill the magazine. It does give it a nice uncluttered look ... perhaps you prefer it.

QST uses the standard three column format, which was no surprise.

In time we should settle down in *73*. We'll use four columns and see how we and you like it. We'll try to get our diagrams settled down in size and go for nice big and clear photographs.

Several readers seem to have accepted the idea that the larger magazine is in some way magically less expensive than the smaller one. It sure would be nice if this were true, but It is just another myth. The monthly cost of printing *73* varies with the size of the magazine, and that varies with the number of ads ... the more ads the more articles you get ... remember that, if you happen to work for a ham manufacturer, ham dealer, or computer firm ... or if you have any dealings with any such. At any rate, after four issues at the new size I can tell you that the cost of putting out *73* has gone from around $25,000 a month to around $40,000, just as I said it would. Now who do you think is going to have to pay that extra money? You know darned well ... it will come out of your pocket one way or another ... some in increased subscription rates, some in increased prices on ham gear. Hopefully you are enjoying the new big size enough not to care about the few extra bucks. If you add in the additional postage costs it isn't all that few bucks. The tab comes to perhaps $250,000 extra a year in printing costs and postage. That's $2.50 each for 100,000 readers! Enjoy ... enjoy.

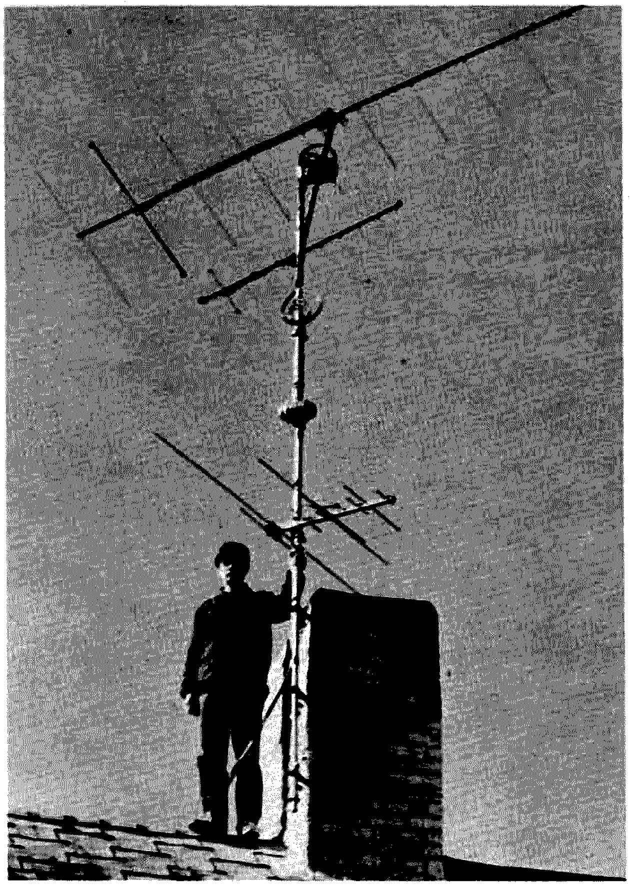
PROCESSING OSCAR

Here's a picture of Franklin WB4BWK who, together with VE2BYG/3 ... now VE3SAT, made the first computer-to-computer QSO via Oscar 7 mode B on October 9th last. This came about on orbit 4101 using ASCII RTTY ... a ham radio first.

Franklin has now interfaced his Oscar station with Erskine College's PDP-11 minicomputer and he is looking for RTTY/ASCII contacts via Oscar 6 or 7, mode A or B.

PEACEMAKER?

A note from a reader out in Michigan grumbles that he has been warned that his newly installed pacemaker should not be exposed to rf ... like diathermy, microwave ovens, transmitters and such. I suspect that he has been over-cautioned ... those ovens are extraordinarily shielded and a well matched and grounded ham rig should have little detectable rf around. How about it all you experts, what is the story? Do pacemaker hams have to run QRP and eat in places without microwave ovens?



PAYING FOR REPEATERS

As more and more repeaters are put on the air, the question of who is going to pay for them gets stickier and stickier. It isn't all that difficult where there is a bonafide repeater club which is handling the situation ... having regular meetings, classes for newcomers, charging dues, putting out a newsletter, etc. ... but where an individual has set up a repeater and then tries to force the users to reimburse him for the expenses involved ... that's going to take some discussion.

Not a few complaints have been received by *73* over this problem. Typical is a user gripe about WR1ABN in South Walpole, Mass., just outside Boston. This 147.69-.09 repeater is using a public channel and thus keeping other repeaters from being able to use it ... and there are quite a few groups that would dearly love to get the channel. A recent letter from Mario K1UHU, the proprietor of the repeater, asked for contributions. A local amateur who supports two local repeater clubs with dues got this letter and, when he didn't send the demanded money, says he was asked by K1UHU to get off the repeater and stay off.

My own reaction to such a demand would be to get madder than hell. I know for a fact that several of the locals who have gotten this rude treatment did react as I would. Thus we have a really miserable situation ... amateur radio is supposed to be fun, yet we have UHU out there doing his darndest to louse it up for a lot of people ... including himself. He has come on a great way to get unending kerchunkers and unsolicited nasty comments, as many arrogant repeater owners have discovered.

How would you feel if you got hit with something like this? It isn't practical to pay money to every repeater in your area ... few can afford it. Does that mean that unless we pay someone off we can't use a repeater? With the serious shortage of repeater channels in most areas perhaps it is about time to ask the coordinators to assign the best channels to the free and open repeaters ... the next best to clubs with a relaxed user policy ... and what is left, if anything, to people who want to charge for use of their repeater ... and move them off to 220 or up when a legitimate group needs a pair.

Not wishing to be controversial about things, I'll say no more ... right now ... so no mention of Tony Baloney and his pirate group will be made ... tempting though it may be.

DEREGULATION AND CB

One of the biggest turnarounds in communications has been the enormous change in citizens band operations ... and the amateur reaction to this change. Just a couple years ago CB was a dirty word to most amateurs and they wouldn't be caught dead operating on eleven meters. Today tens of thousands of amateurs are getting with CB and joining in the fun there.

There has been a big change in CB due to the relaxation of the FCC rules permitting what had previously been illegal (virtually all of the CB communications), the present extreme low in sunspot activity and resultant lack of 11m skip, and the large influx of truck drivers spreading their friendly greetings to each other ... and to the little four wheelers getting in their way.

I remember just a little over a year ago when there was one other local amateur on CB ... Herman WA1MYS. Now I think a third of the local club members have a CB rig in their cars ... and the rest are getting edgy.

A couple years ago the few ham clubs which had tried to scout the CB ranks for ham prospects reported discouraging results. Now it appears that a good percentage of the ham club Novice classes are filled with CBers ... all anxious to move up to a ham ticket.

Okay, you are not going to see the original manuscript of this column, but instead of being typewritten, it is being hand printed. Seems that my typewriter has "once more" developed the "flu," or in its case, some broken springs. A, S and V have gone to the "happy hunting ground" with B and F not far behind. Before the situation developed to the "point of no return," I felt it incumbent to take the necessary steps to remedy the situation, and now "Blue Boy" (the pet name of my typewriter, so awarded in honor of its particular color) is back at the manufacturer's service center getting a quick rebuilding. Hopefully, he will be back in service by this time next month; however, in the interim, it's back to the old way — ball-point pen and lined paper. My goodness, it feels strange! Shades of PS-247.

How many of you know what happens when you send in that form 610 to renew your license? How many of you even know how a test is graded at the FCC office in Gettysburg PA? These were some of the points covered at the FCC Forum at SAROC '76. Representing the Commission was the chief himself, John B. Johnston K3BNS, head of the Amateur and Citizens Division. Now, I have been to a lot of talks given by a myriad of "officials," but I have never seen anyone as warmly received as Johnny. It is obvious that the amateur community likes this guy and, even more important, he likes us, and is willing to work with us to build a bright future for the amateur radio service and its members.

Through the use of color slides, John began his talk by taking us on a trip 2500 miles east to the city of Gettysburg PA. We met John's staff and learned how both amateur and citizens radio service licenses are processed, how STA's are issued, and many of the other intricate workings of his organization. In all, that part alone was quite an education, one that every amateur and CBer should be given. To say that Gettysburg is inundated with CB applications is the understatement of 1976! John's color slides and commentary explained the current problem with processing vs. time quite graphically. If we didn't understand or were unaware of their problem before, we sure understood it after this presentation.

Then John got into the meat of his dissertation: the future of the amateur service. He made it very clear that his intention was to deregulate wherever possible to enable amateurs to continue to experiment and develop new techniques and communications art forms. Wherever possible, we, the members of the amateur community, would be granted the necessary freedom to build toward a more viable amateur service, one designed to meet the needs of the future and one that would be as self-regulating as possible.

Since much of what he said has already been covered in *HR Report* and other publications, I will refrain from a long dissertation here. Suffice it to say that John is willing to work "hand in hand" with us to build a lasting future for amateur radio — at least that's the way I read it. I think that the amount of deregulation in the past few months tends to bear out this feeling. Anyhow, if no one else has said it to date, I will. From all of us: "Thanks, John. We are proud to have you as one of us."

Now this leaves a few questions. Will we be able to handle the responsibility that deregulation places upon the shoulders of us all? Are we willing to bury our personal prejudices and begin to work "hand in hand" with one another toward the future? Are we mature enough to be truly self-directing? If each of us is willing to do his or her share, regardless of how insignificant that share might seem at the time, we can and will make deregulation a success and moreover prove the confidence that John has in us to be well founded. Deregulation is a challenge, but I think that we are ready to accept it. More on this topic, a lot more, in future months of "Looking West."

And I wrote, "Believe it or not WR6AJP is a full-time 24 hour-a-day open autopatch that operates on an inverted split-split and has never been down due to technical failure" or something along those lines. I think that the AJP repeater read my mind, for just about the time the story was published, it did "go down" due to a technical problem. However, to Jim Hendershot WA6VQP, its owner, the whole thing was just the necessary motivation needed to build the new system he had been planning. According to Jim's schedule, the "new improved WR6AJP" will be back in service within 3 weeks, and once again the San Fernando Valley will have its favorite autopatch.

AJP's story is a very interesting one, in that Jim never meant it to become the popular system that it is today. As he tells it, the whole thing began as a fun project using a Motorola HT as a receiver, a single tone surplus decoder, and a Knight TR-108 transceiver for a transmitter. It was an experiment to gather data on Jim's part, and over a period of less than two years, it has evolved into one of the more popular open systems in the Los Angeles area, and one of our very popular open autopatches. More recently, Jim has taken on an even bigger responsibility. He was asked to serve on the SCRA's Technical Committee for the '76 year by the SCRA's new chairman Bob Thornberg WB6JPI, and has been handed the challenge of developing a set of "standards" for amateur use of touchtone in autopatch service. If you have a number of autopatch systems that you frequent, you might well be aware that in many cases it requires different tone levels to activate the decoding equipment to access, control, and use a given repeater equipped with autopatch service, be it open or closed. The establishment of standards for this, along with other forward-looking ideas, seems to be the goal for this year's "SCRA."

As mentioned earlier, Bob Thornberg WB6JPI has been elected the new "Mr. Chairperson" of SCRA, replacing Dick Flanagan W6OLD, who has retired after 3 hard years of service to that organization. The election of Bob to this post is interesting in that he is not only a repeater owner/delegate to SCRA, but he is also one of the most visible people involved in the Southern California FM scene. One might say that he not only represents the choice of the repeater owner, but the interests of the repeater user as well, for if the average repeater user were asked his or her choice as to who should be SCRA Chairman, the answer would probably be 'JPI.

Simply, Bob believes that people can solve their own problems, and is one of those rare individuals who possesses both technical expertise and common sense. Along with Burt K6OQK, he developed the inverted tertiary split plan fast becoming known as the "California Split Plan." He formed the first user support organization for an open repeater, the Mt. Wilson Repeater Association, a system of user support now being widely copied. He is one of the "good people" who is willing to listen to

Touchtone Decoder

--using a calculator readout

With the advent of 2 meter FM and associated repeater systems, the "touch tone" system has found wide acceptance for both repeater control and dialing up autopatches. Probably the greatest reason for the touch tone system is the readily available touch tone pad, which is "ready made" and quite accurate in tone generation.

There are also a variety of touch tone decoding systems that have been devised. Most of these work well and generally control some major function of the repeater. When someone is dialing a function or placing a call with the autopatch system, I thought it would be nice to have a simple device that would read out the numbers dialed and retain them on a display until cleared manually.

The idea finally struck me that an el cheapo calculator would serve perfectly in this application. Just about any calculator can be used, yet retain its calculating ability while not serving as a memory. If you will observe the normal operation of a calculator, it progressively retains the digits entered on the keyboard. When the clear key is depressed, it erases this entry of numbers. Therefore if we were to parallel switches with the calculator keyboard switches and activate these switches with a touch tone decoder, the calculator would display the decoded digits until the calculator display range was exceeded or the clear key was depressed. Of course a 12 digit calculator is most desirable due to the number of digits it can retain in one display.

The first step is constructing a reliable tone decoder that is relatively insensitive to noise, etc. I have had very good results with the touch tone decoder described in the *National Linear Integrated Circuit Handbook.* This system uses the National LM567 which has high noise rejection, immunity to false signals and a very stable center frequency. The 567 Phased Locked Loop decoder was quite expensive ($9.00 each) until they sprang up on the surplus market. Radio Shack stores are now selling them for $3.50 each, which is not too bad. Seven of the 567s are required for the decoder and 3 SN7402 quadruple 2 input positive NOR gate ICs are used in the total decoder system. Fig. 1 illustrates the basic touch tone decoder. The complete decoder at present surplus prices can be constructed for about $30-$35.00.

The output (pin 8) of the 567 is normally "high" or at a potential of 5 volts. When a tone is decoded by the 567, the output goes low or nearly to ground potential. The desired frequency to be decoded is selected by the 10k potentiometer attached to pin 6. All of the 567s decoding as a group activate the proper 7402 gate and the output pin of the 7402 goes from a low to high state. This lends itself well for driving an NPN transistor which may switch whatever you desire.

If you want just an indicator lamp for each number that is decoded, an LED may be turned "on" by the NPN transistor with an appropriate current limiting resistor. I was fortunate enough to find a batch of 24 volt, 350 Ohm relays with four single pole contacts on each relay. At 24 volts, they required about 10-15

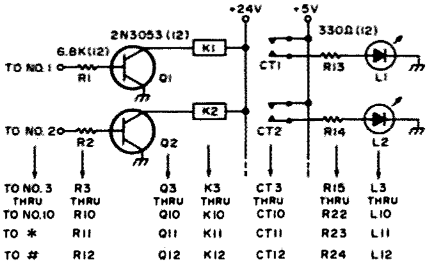

Fig. 2. Tone decoder drivers.

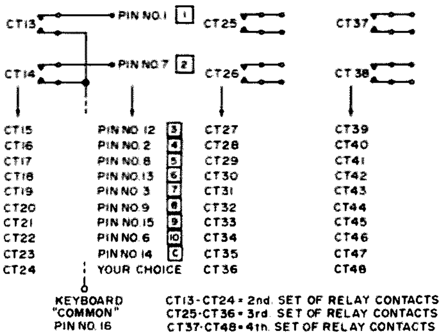

Fig. 3. Decoder/calculator interconnections.

milliamperes for reliable closure of the relay. The 2N3053 NPN silicon transistors drove these relays nicely. No doubt you will be able to find surplus telephone type or military relays that will meet these requirements. If you don't go the surplus route, the relays may cost as much as $5.00 each. No doubt some of the surplus houses in *73* will be able to provide inexpensive relays. See Fig. 2 for the transistor relay driver system.

Each 567 tone decoder can be "tuned" by either the use of an audio signal generator or a touch tone pad. The desired tone frequency is fed into the separate 567s while metering pin 8 (output) of that decoder. A fairly high level of audio should be fed in at first and the 10k pot should be varied until the output drops to zero. This will indicate that you have arrived at the decoding frequency. Keep reducing the audio level and varying the pot in small increments until you find the lowest level at which the 567 will detect. This will be the most selective and sensitive position for the 567. This procedure should be continued throughout the remaining tone decoders.

If you do not have access to an audio generator, a touch tone pad may be used for alignment. (See Fig. 4.) By depressing the proper *pairs* or combinations of numbers on the touch tone pad, you can create the specific frequencies needed for alignment (this may not work on some newer pads). Follow the same procedure as that used with the audio generator. Should you have access to a frequency counter, it might be wise to test your particular touch tone pad to make sure it is on frequency. It might be especially "prudent" to do this if the pad was given to you or if you purchased it at a special sale price.

The first set of relay contacts on the 12 relays are used to activate LED readouts. The second set are in parallel with the calculator keyboard. The third and fourth sets are for anything you so desire. The main reason for using relays rather than solid state devices is to compensate for the wide variety of calculators on the market. Some of these employ a positive ground and others, a negative ground system. Relays may be wired to either system without need for a PNP or NPN type of solid state switching device. Check out your particular keyboard as it may require a common bus to all switches or individual leads to all switches. If in doubt, wire all of the keyboard switches separately to the relay contacts. Only keyboard switches 1 to 0 will have to be wired to the relays. * and # relays could be used to clear or add the calculator in some clever setup.

Fig. 5 is the schematic and wiring system for the Western Electric touch tone pad. This is the configuration used for tuning up my decoder. The 500k pot is adjusted for desired output.

Audio Frequency	Press These Touch Tone Pad Buttons Simultaneously
697 Hz	(1, 3) (1, 2)
770 Hz	(4, 5) (4, 6)
852 Hz	(7, 8) (7, 9)
941 Hz	(*, 0) (*, #)
1204 Hz	(1, 4) (1, 7) (1, *)
1336 Hz	(2, 5) (2, 8) (2, 0)
1477 Hz	(3, 6) (3, 9) (3, #)

Fig. 4. Pairs that may be pressed to generate single alignment tones.

Fig. 6 is the regulated 5 volt power supply for the basic tone decoder. The relay power supply depends on the particular voltage relay you are able to obtain on the surplus market. With relays, the power supply filtering and regulation need not be critical. A simple bridge rectifier and filter capacitor should be adequate for the relays. Remember, however, that the dc output will be at least 1.4 times the ac voltage rating of the transformer with the bridge/filter capacitor supply.

This system provides an inexpensive touch tone memory that can be tailored to your requirements. The next time someone threatens to turn the repeater off through some "magic" combination of touch tone numbers, your "el cheapo" calculator will remember them. You take it from there — hi! ■

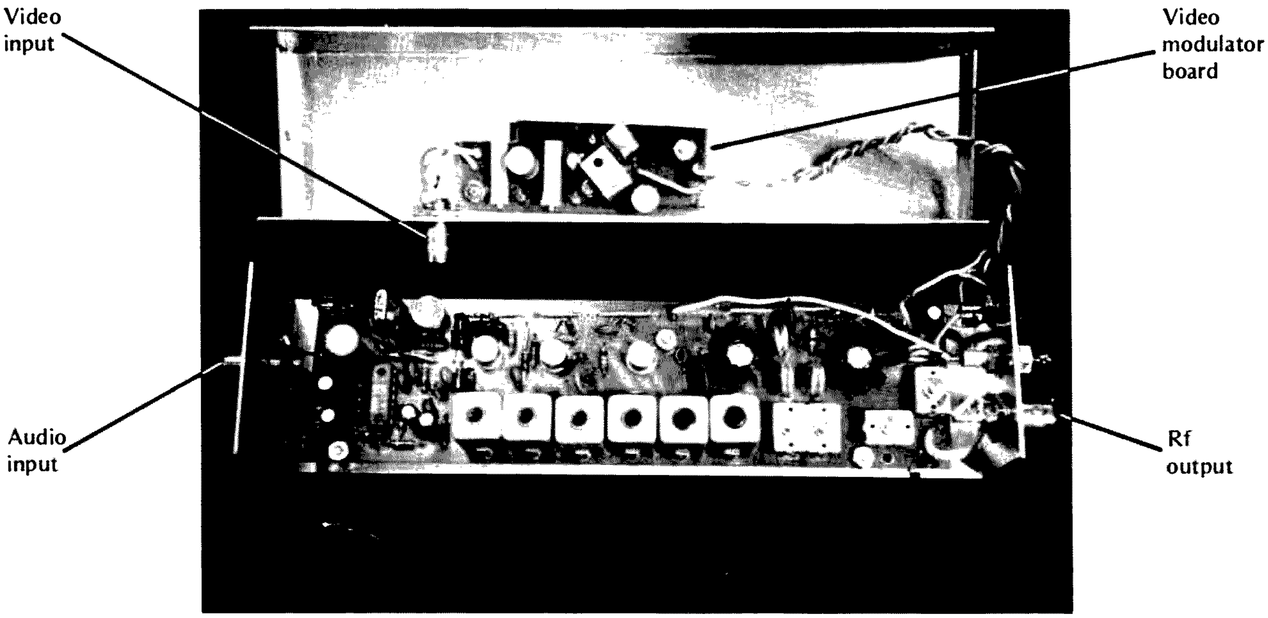
Simple Amateur TV Transmitter

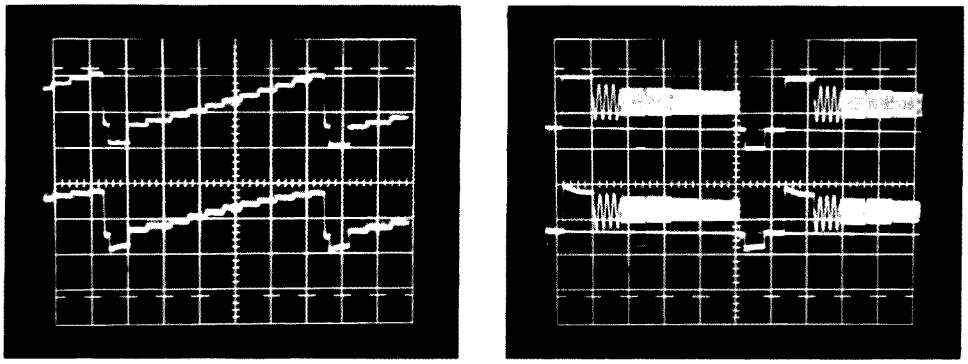
-- at a QRP price



C

Fig. 1. 3/4 Watt ATV transmitter. (a) Mike input side; (b) output side; (c) internal view.

Smaller than a box of spaghetti and costing about $55 to build, this 3/4 Watt 3/4 meter ATV rig can simultaneously transmit AM video and FM audio on the video carrier. The unit is basically a VHF Engineering TX-432 transmitter, which is collector modulated using the HR-440 video modulator described in the Nov/Dec 75 *73* (pp. 42-43). Good linearity and excellent frequency response is achieved as shown in Fig. 2. Power drain is approximately 350 mA at 12 to 14 V dc.



A B

Fig. 2. Performance curves (all vertical scales uncalibrated). (a) Linearity: top scale, video in; bottom scale, detected rf output; 10 usec/div horizontal; 3/4 Watts out (ave.). (b) Frequency response: top scale, video in; bottom scale, detected rf output; 10 usec/div; 3/4 Watts out (ave.); burst order (in MHz) – 0.5, 1.5, 2.0, 3.0, 3.58, 4.2.

Applications

What can you do with a QRP ATV transmitter? Possible applications include:

1. Operating as a primary station rig, it can provide snow-free pictures over a 5 mile line-of-sight path between stations using 10 dBd gain antennas and 2.5 dB noise figure preamps. Better performance can be expected in areas where inversion layers are prevalent, such as Southern California. Especially effective operation results when used in conjunction with an ATV repeater. For example, W3API, located 3 miles from the WR4AAG TV repeater in Alexandria, Va., can send snow-free pictures to W3IRL who is 45 miles away in Baltimore.

2. The rig can be used as an exciter for a 1 Watt in, 10 Watt out linear amplifier such as the quasi-linear Motorola MHW-710 power module. (See Nov/Dec 75 *73*, p. 39, and Motorola MHW-710 data sheet #DS 5522 R2.)

3. It can be mounted inside a portable TV camera to create a self-contained hand-held station. If placed in a large R/C model airplane or rocket, such a system could provide some spectacular pictures.

4. It is ideal for general mobile applications (e.g., auto, aircraft) due to small size and power consumption.

5. Low power consumption also lends itself to solar-powered operation suitable for remote unmanned usage such as hidden transmitter hunts.

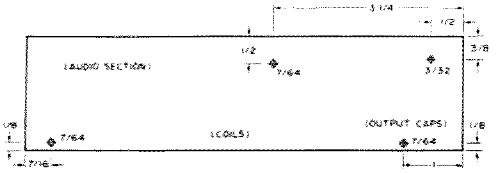


Fig. 3. TX-432 PC board drill guide. All dimensions in inches. Foil side down; component side up.

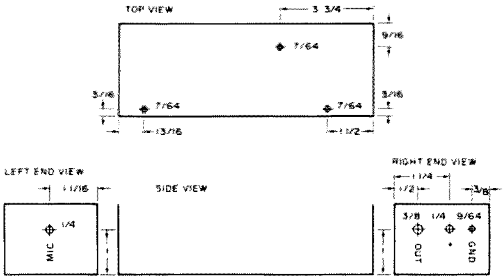

Fig. 4. TX-432 chassis drill guide. All dimensions in inches. All measurements from outside edge of chassis. Chassis is LMB #850. Guide not drawn to scale.

Modification Procedure

1. Drill holes in PC board and chassis using Figs. 3, 4 and 5 drill guides.

2. Construct, tune up and test TX-432 transmitter strip per manufacturer's instructions. Be careful that capacitors soldered to L1-L6 do not touch the coil cans. If necessary, insulate the inside surface of the cans with tape.

3. Locate coil L11. Unsolder the end connected to the +12 V dc line. Mount a miniature insulated terminal in the 3/32" hole provided by Step 1, above. Solder loose end of L11 to terminal (Fig. 6).

4. Mount all components to the video modulator PC board as described in the Nov/Dec 75 *73*, page 42, with the following exceptions:

a) R2 will be 100 Ohms.

b) Do not clip off tabs of D40 and D41 transistors. Instead, bend tabs down as shown in Fig. 1. Bend tab of D41 down and back onto itself to prevent the tab from protruding beyond the edge of the PC board.

5. Solder 6", #22 stranded wires to ground, +, and OUT on the video modulator board. Twist ground and + wires together. Solder 1" long wires to ground and IN at the other end of the board.

6. Solder 2½" length of RG-188 to the output of the transmitter board. The RG-188 shield length, soldered to ground of board, should be as short as possible.

7. Using 3/16" standoffs, #4 screws, lockwashers and nuts, mount the transmitter and modulator boards to the chassis.

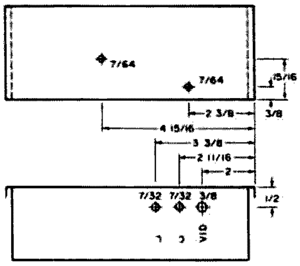
8. Mount VID (video in) and OUT (rf output) BNCs to chassis. Also mount phono jack, feedthrough capacitor and two ground lugs using a #6 screw, lockwasher and nut. One lug is mounted inside the case; the other, outside.

9. Solder shield and center conductor of the RG-188 from the transmitter strip to the OUT BNC. The shield should be soldered directly to the threads of the connector and should be as short as possible.

10. Solder a #22 insulated wire from the feedthrough capacitor to the +12 V dc line on the transmitter board. Solder the ground lug on the chassis to ground on the board. Solder wires from the phono jack to mike input and ground on the board.

11. Solder 1" input and ground wires from the video modulator board to the VID BNC. Solder twisted + and ground wires from the same board directly to the feedthrough cap and ground lug on the chassis, respectively. Solder the wire from OUT on the video modulator to the insulated terminal (one end of L11) on the transmitter board.

Fig. 5. TX-432 chassis cover drill guide. All dimensions in inches. All measurements from outside edge of chassis. Chassis is LMB #850. Guide not drawn to scale.



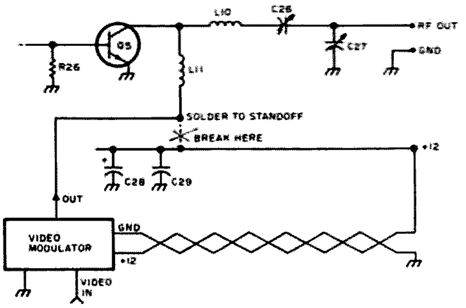


Fig. 6. Modification schematic.

12. Apply stick-on lettering to the case as shown in Figs. 1, 4 and 5.

(Tuneup)

13. Connect the output of the rig to a wattmeter with a dummy load or through-line wattmeter with an antenna. Turn "L" (level) control on video modulator fully clockwise and "C" (contrast) control fully counterclockwise. Connect a 12-14 V dc, ½ A regulated power supply to the + and GND terminals. Connect a composite 1 V P-P video signal to the VID connector. Monitor the rf output on a converted TV receiver.

14. Adjust C24, 25, 26 and 27 on the transmitter for maximum power output. Approximately 1 Watt should be obtainable. Alternately turn "L" counterclockwise and "C" clockwise for best picture on the TV receiver. You may have to readjust C24-27. Do not set the contrast too high or else sync buzzing will occur on the audio channel. (As described in the Nov/Dec 75 *73*, p. 40, a separate FM receiver is required to demodulate the audio.) During this tuneup procedure you will note that the "C" control affects only contrast while the "L" control will affect both output level and contrast. In general, the higher the output level, the lower the contrast. A good picture at 3/4 Watt will be possible.

Parts List

Part #	Description	Qty	Unit Cost	Total Cost	Source of Supply
1	8-1/2 x 2-1/8 x 1-5/8 Chassis; LMB #850	1		2.50	Electronic Supply

TX-432 Transmitter kit is available from VHF Engineering for $39.95 (PO Box 1921-7, Binghamton NY 13902).

Required Tuneup Tools

1. 0.075" plastic hex alignment tool (GC #9304; $0.55)
2. Phenolic screwdriver

Notes:

1. A 0.5 Amp regulated 12 to 14 volt power source is required.
2. The crystal is a commercial standard, 20 pF in an HC-25 package. Frequency is desired rf frequency divided by 24.

Acknowledgements

I am grateful to Charles Spitz W4API, for providing the TX-432 transmitter strip and other needed components. Terry Fox WB4JFI provided valuable suggestions and test equipment used for optimization of the modification design procedure. ■

Amateur TV Receiving System

-- some of what you wanted to know

Because of practical and regulatory considerations, amateur television (ATV) transmitted power levels must be considerably lower than those radiated by commercial broadcast stations. To attain reasonably long operating ranges, the ATV receiver must compensate for what the transmitter cannot do. Thus, it must exhibit a considerably greater sensitivity than that required for broadcast reception.

An increase of only 3 dB in receiver sensitivity can make a noticeable improvement in picture quality. It is therefore important to squeeze every last dB out of a receiver system – and getting those extra dB at 440 MHz is far more difficult than on the lower frequency bands. Nevertheless, through proper component selection, a high performance and reasonably priced receiver is a reality.

Throughout the past two years, the Metrovision Amateur Television Club of Greater Washington D.C. has been examining numerous components and configurations in an effort to engineer an ATV receiving system with the following characteristics:

1. Excellent sensitivity.
2. Reasonably low cost.
3. As many off-the-shelf and readily available components as possible.

These design goals were established at the outset with one overall consideration in mind – that is, to make it as easy as possible for people to receive ATV.

Based upon these goals and after considerable testing, such a system has been developed and has proven to be successful. Fig. 1 shows the configuration and Table 1 lists recommended components, costs and sources of supply. Specific brands are stated in lieu of providing only generic names. This is necessary since performance varies greatly from product to product. For example, a Radio Shack UHF-to-VHF converter, which performs well for commercial broadcast reception, is a bummer for ATV work. It should be emphasized that the Metrovision ATV Club is a non-profit group and has no financial ties to any of the companies mentioned. The recommendations are totally objective and based upon 2 years of comprehensive on-the-air tests. Furthermore, the equipment recommendations pertain only to optimal reception of wideband TV signals in the 3/4 meter band and may not necessarily be the components desired for receiving other signals such as narrowband FM or moonbounce.

In addition to providing a picture, this configuration will allow audio to be heard on the TV receiver only when the receive signal employs 4.5 MHz subcarrier audio (FM audio located 4.5 MHz above the video carrier). Incidentally, this is the output format used by an ATV repeater. When operating simplex and receiving a signal using an audio-on-the-video carrier format, a separate FM receiver must be used to pick up the audio. Low cost receivers for this purpose include the VHF Engineering RX432C kit ($79.95) or surplus Motorola UHF Pocket Pager (under $40). The antenna of these receivers could be a short piece of wire wrapped around the preamp output cable to provide signal coupling from the large antenna.

Keep in mind that your investment in good transmission line and an antenna is doubly worthwhile since these components will also be used when you're ready to transmit ATV. Try to get your antenna up as high as possible and away from nearby obstructions including trees. When conditions are right, don't be surprised if you get some good ATV DX!

ADDENDUM
Blonder-Tongue UHF-to-VHF Converter Modification

A modified commercial UHF-to-VHF converter connected to the antenna terminals of a standard home TV tuned to an unused channel between 2 and 6 is the simplest and most effective means for receiving a fast scan amateur video signal. The lowest frequency normally tuned by a converter is about 460 MHz; therefore, modification is required to enable the converter to tune

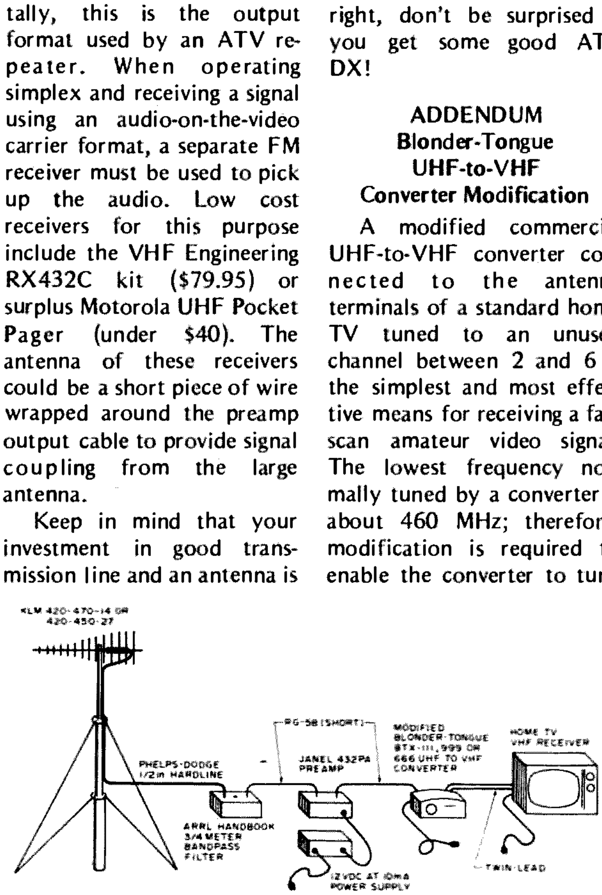

Fig. 1. Recommended ATV Receive Configuration.

Description	1975 Cost (Subject to change)	Source of Supply
I. Antenna

Note: RG-8 cable can be used for runs up to 50 feet. Measured loss ≅ 3 dB/50 feet (2 dB worse than hardline).		

down into the 420-450 MHz amateur band.

Considering sensitivity, stability, and cost, the best converters for amateur use are the Blonder-Tongue BTX-111, 999 and 666. All of these units can be modified using the same procedure as follows (see Fig. 2):

1. Remove six screws from back and pull off channel knob from front.
2. Spreading out top and bottom of plastic case, push out chassis by applying pressure through rear rectangular opening.
3. Locate C1 on top of chassis (see Fig. 3). Gently turn clockwise as far as it will go. You have now changed the tunable frequency of the unit down into the amateur band.
4. From underside of the chassis locate L1 (see Fig. 4). It is a semicircular strip of metal located in the center of three sections along the main tuning control axis. Locate the point where L1 connects to L2. (L2 is two short parallel wires running between the center and rear sections.) Solder a 2-8 pF subminiature variable capacitor (e.g., Erie ceramic) in electrical parallel with L1 — one lead of the cap connected to the L1-L2 junction point and the other

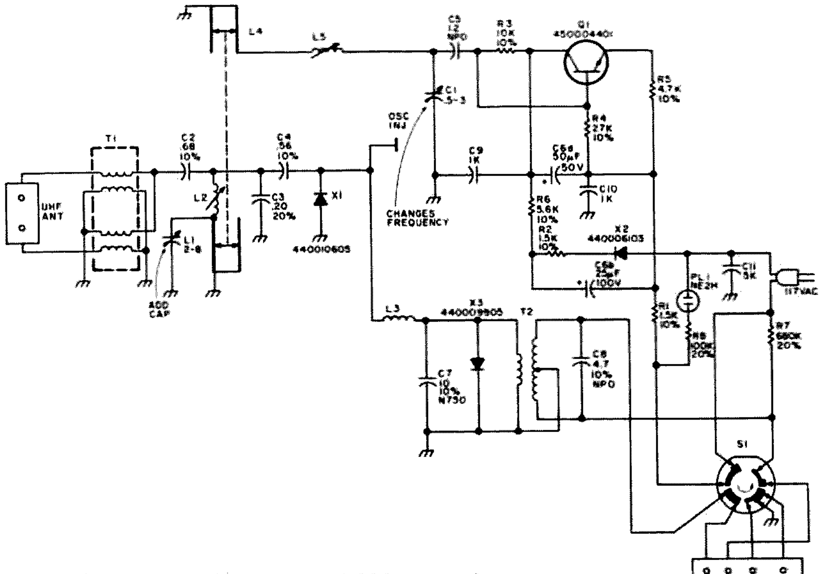

Fig. 2. BTX-999 Schematic. BTX-111 and 666 are similar.

III. Tunable 3/4 meter bandpass filter; Construction details in ARRL *Amateur Radio Handbook* or VHF manual Note: Filter greatly improves receive picture quality through reduction of out-of-band noise including commercial 450-470 MHz service and UHF broadcast TV signals.	About $5.00	Local electronics dist. and hardware store
IV. Preamp; Janel #432PA, comes fully built in chassis with BNC connectors. Requires 12 V dc @ 10 mA filtered power supply (e.g., Lafayette #99F50742, $10.95)	$33.00 postpaid	Janel Labs 260 N.W. Polk Ave. Corvallis OR 97330 (503) 757-1134
V. Modified UHF-to-VHF converter, Blonder-Tongue. Any of the following will work: a. BTX-666 b. BTX-999 (Same as 666 but has fine tuning control and channel light) c. BTX-111 (Same as 999 but has post amp, exhibits slightly better performance than other two if preamp is not used. If preamp is used, as is the case 95% of the time, all give equal performance.) Notes. 1. See Addendum for modification procedure which is identical for all units. 2. Make sure converter has a brown case. Earlier versions which were unstable used ivory cases.	 $20.00 approximately $23.90 $33.70	Lafayette Radio 111 Jericho Turnpike Syosset, L.I., NY 11791 (516) 921-7500 Stocks only BTX-111 (18F18319)
VI. Unmodified Home TV Receiver Notes: 1. Connect output of converter to VHF antenna terminals on TV set. 2. Turn channel selector to any unused channel between 2 and 6.		

Table 1. ATV Receive Configuration Component List.

lead to ground (wall between center and rear sections). Position the capacitor to permit easy access for adjustment.

5. Drill ½" hole in the bottom of plastic case to allow access to the capacitor after the unit has been "buttoned up."

6. Place the chassis back in the case along with the six screws in the rear and the knob in the front.

7. Connect the antenna transmission line (from the T/R relay or preamp) to the UHF ANT terminals of the converter. Connect 300 Ohm twinline between the converter's TV set terminals and the VHF antenna terminals of your TV receiver. Connect your existing commercial broadcast antenna to the VHF ANT terminals on the converter.

8. Tune your TV set to an unused channel between 3 and 6. Place converter front panel switch in UHF position. In general, the amateur band will be found between channel positions 14 and 20. Using a non-metallic screwdriver, adjust the capacitor for best picture. It need only be adjusted once. ■

Glass Arm

--the dreaded CW man's disease

This is the age of the Natterer. SSB, FM via repeater, Teletype, slow scan. And a little bit of Hand Modulation, mostly confined to Novices and old men.

Nearly all the old men use an electronic keyer of some sort, usually a very complex sort. A very few use the mechanical Vibroplex. None use a hand key, so far as I know. Only Novices use them, and in most cases, pretty badly. This is a pity, for the fluent use of a hand key is less a skill than a knack. In any case, the art has long since been lost.

There are any number of books that tell you how to hold and operate a hand key. Every book on learning code does, whether it's the Army Training Manual or those produced by various magazine and book publishers. They tell you everything but how to send, as long as you like, without acquiring Telegrapher's Paralysis, or "Glass Arm." Either they never heard of it, or think it wiser to leave the question alone. While very few of us use keys much, it *is* nevertheless a very useful and important skill.

The QRPP boys climb mountains with their two pound CW transceivers – besides VFO-buffer, FET, four transistors and an IC, the thing has to have a solid state keyer which is even more complex than the unit it serves. How nice if a small mechanical key – homemade – were mounted on the clipboard used for copying. Or even one of those Japanese dollar keys that have been kicking around for the last twenty years. Compared with the "good" solid brass telegraph keys, they never induce a "Glass Arm" – while the "good" ones will. So, the Japanese ones not only save money, weight, battery power and bulk, but they also save arms and improve sending, too.

It helps in your FCC examination if you can send properly. Only one in ten, or so, fail because of sending, but even that is too much. The straight keys are mounted on each desk where candidates sit. They are easily adjustable, and are usually left in some weird setting, such as with a half inch contact spacing.

The receiving exam eliminates many of the applicants, so that the examiner has only a few to watch, as he prepares to listen to each one. As each hopeful adjusts the key to his liking, the examiner makes bets with himself about who will fail and who will pass. He gives each applicant a paragraph out of a manual to send.

It is easy to tell if you passed. The examiner does not congratulate you and shake your hand; he listens to your four or five Vs and the first two or three words, and says, "That's enough." You'd like to finish the paragraph but he won't let you. From the first two or three words he knows that you could send for fifteen minutes without a mistake if allowed. He knows telegraphers; he's one himself. If he lets you send two sentences, you may scrape by. Half a paragraph only if he thinks he can find therein some excuse to pass you.

Receiving, of course, is an entirely different matter, requiring different skills. It is very definitely harder, as any ham knows.

In sending, there are two schools of thought about the management of elbows: on the table and off the table. If you embrace both, the key must be mounted on a board with a non-skid surface, so that it may easily be moved as required.

A hand key requires complete control. The hand must be easy and relaxed, but still in full control of everything the key-lever does. Do not depend on the return-spring; its function is to keep the key open when idle.

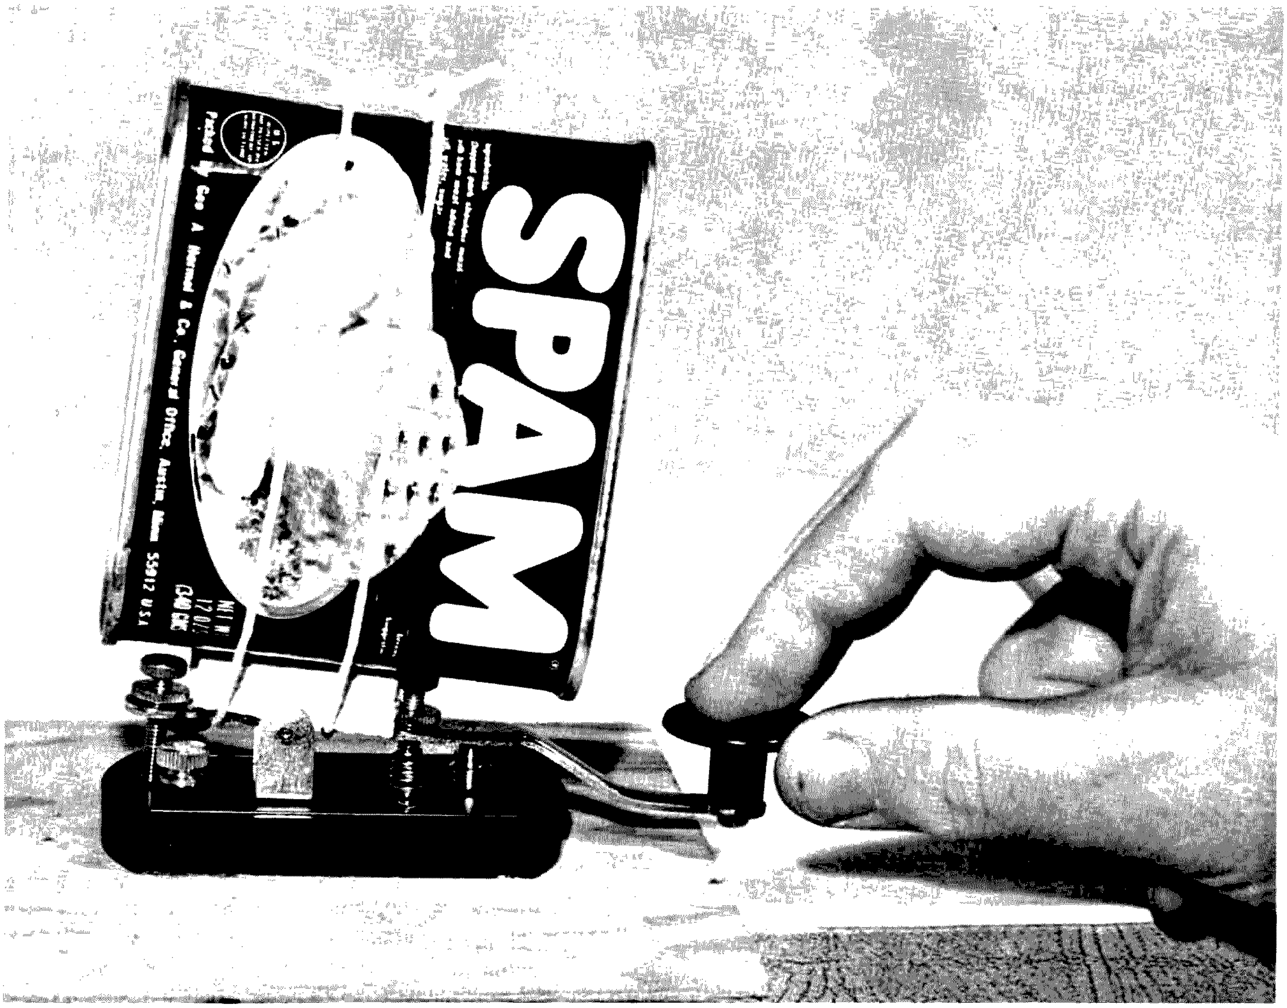
For your first practice session (of *course* you have to practice, but not for long) the key return-spring should be removed entirely. Put the spring in a glass jar so it doesn't get lost.

Now, in order to send, you have to "pump" the key-button up and down, holding it between forefinger and thumb. It is just as important to lift up as to press down.

A very good exercise is a long, slow series of dots. It is even better to time this by saying aloud: "Dot, uh, dot, uh, dot, uh," making the mark (dot) and space (uh) as nearly the same length as you can. When you get into the rhythm of it, it's easy. But don't speed up.

Silly as it sounds, this exercise will do a lot for you. Do it only until you begin to get tired of it, then quit, put the spring back in and send normally for a while. Don't push it. Next day, the same. When the dotting gets easy, then you don't need it any more and can forget it.

You will discover some-



thing: You won't like the spring as stiff and heavy as you did before. Not really light, but not heavy at all.

One precaution: Don't let the family or friends hear you going "Dot, uh, dot, uh," because they'll think you're going dotty.

Only you can tell how much it has helped your sending. It will be less "choppy" and "itchy" than before. And you will develop a sense of timing that helps, not only with hand-sending, but also with many keyers. You won't need any "self-completing" feature, because you will be the boss of the keyer, not its victim. I have seen a keyer shake a man like a dog shakes a rabbit – a nervous phenomenon we'll come back to later. Learn to send even dots. It takes less than half an hour, spread over the week, and your sending – even on a printer keyboard – will improve. *And* be easier and more fun.

After dotting, dashing is even easier. Again you time it with words or syllables: "Da da *dash* uh dot uh dot uh dot ha ha ha da da *dash* uh da da *dash* uh da da *dash* ha ha ha da da *dash* uh dot uh da da *dash* uh da da *dash.*" Boy! – what a way to write it! The da-da-dash is all mark, key down, of course. It times the dash as equal to three dots run together, as it should. The "uh" is the unit space as before.

Now, we need a word space. "Uh uh uh" sounds like admonishing the cat, so I have substituted the friendlier "ha ha ha" as a three-unit space.

Of course, you can substitute French or Japanese or whatever, and in any case you don't have to practice this long. You need the practice only so long as it isn't easy. When it is, you have graduated. Don't make work out of it – do it for fun, and see how fast your sending improves.

I have emphasized slow sending – slow and even, with dots and unit spaces of like weight – because this prevents a jittery, choppy style which is hard to read and murder on the fist. It sounds a little heavy, but your dots never "drop out." And when you take your exam you will find that the black, cast iron Beast from Hell with the oil cup on top of it (which the examiner won't let you look at) is adjusted to send perfect code – not that stuff on tapes and records, and even on the air.

A very good check is to watch your plate milliammeter – you *do* have one, don't you? – or, for practice, send into your ohmmeter. Dotting should read exactly half the key-closed value, if you dot at reasonable speed. In the old days, telegraphers used to adjust their bugs this way, using line current as a guide.

If, in spite of everything (and I won't believe this) you still jitter and suffer from nerves when you send, a good stunt is to weight your key. Now you know what the photograph is about! I used a can of meat because metallic lead is poisonous, hard to handle, and more expensive

than the choicest cuts of meat. Any pound weight will do. A pint of milk, a pound of meat – anything. And it won't be wasted – fasten it on the key temporarily, practice a while, letting it slow and steady you down, and then eat whatever it is for lunch. I did, yesterday.

The British have understood heavy keys for a long time, while we laughed at them. We could send twice as fast with our light telegraph keys, while they used a key you gripped with a fist and – it seemed – pumped water with. We laughed, but did you ever see a Limey Sparks with a glass arm?

Again, try to prevent your friends from seeing the weighted key, but if they do, shrug and laugh along with them. Which of you is learning the most, and who is laughing when he could be learning? You're earning your opinions. Let them have their fun.

So far I haven't mentioned the "tapping" technique. There was once a popular radio organization of "A-1" guys called "I Tappa Key." Do you know who taps keys? Old telegraphers with glass arms and their imitators, that's who.

It seems stilted and pretentious (and inflexible!) to sit down with your feet flat on the floor and send with a hand key, using the edge-grip. This is very much like the Palmer Penmanship Method which we Faithful Old Fellows learned generations ago. And this is no accident. If you write a lot by hand, you either use it, or your hand cramps and you wind up writing an illegible scrawl.

Besides, editors demand typewritten material, and for good reason.

While I write like a doctor, I can send with a hand key as long as I want to – with very few errors. *And* with a Bug, *and* with any solid state keyer.

I had a buddy once, who got himself a glass arm. He could not send even one word with his right hand, so he switched over and relearned to telegraph with his left. It was just a matter of time before the left went too, but he got himself promoted and didn't have to telegraph any more. So there is a remedy, but avoidance is the best policy.

And this is easy. The secret is in the key adjustment – you loosen the "trunnions," or the tightness of the needle-and-cone bearings on each side of the key, until you can shake the key lever from side to side. *There must be as much side-play in the lever as there is up-and-down motion between the key contacts.* That's all there is to it.

You won't believe this. That's all right; I didn't believe it either, until I proved it through experiment. The dollar key I mentioned earlier has *no* side adjustment. Either it has cylindrical ears that poke through holes in the U-shaped mounting bracket, or it has conical ears which should be ground into cylinders. Never mind the sloppy feel; your arm is more important than anyone's opinion. You *need* that slop, whatever key you use.

Probably you have a good solid brass key with side adjustments. Well then, unscrew the side screws and lock them at the point that you can move the lever sideways the same amount that you pump it up and down. It will feel "funny," but send a few minutes – at least a paragraph. If you can keep going, do so.

Now adjust the key up snug. Not to binding, or with noticeable friction; just barely enough to prevent side-motion. Now send, and see how your arm feels. Does it begin to tighten up, and do you begin to make errors?

Loosen the key. You may need a couple of sessions to convince you, if you are on the stubborn side, so there is no need to risk your arm while you decide. But the arm, and how it feels, tells the story. Stubborn or no, I know how that key adjustment will wind up! You will never send with a tight key again!

So much for the practice, now for the theory: Our grandparents used to explain any number of things as being the result of "nerves." The trouble with one word explanations is that they don't lay it out for you. In this case, though telegraphers and doctors alike knew perfectly well that Telegrapher's Paralysis was a nervous condition, only the more observing saw any connection between a tight key and a glass arm. And even *they* hadn't the least notion how such a connection might work.

The first clue came from the work of H. S. Black, of the Bell Telephone Labs, who invented negative feedback amplifiers in the thirties. To him the invention meant stable telephone repeaters, and high fidelity at less cost. But to physiologists, experimental psychologists, and other researchers into the living body and its operation, it offered an explanation that had been lacking before. When you put your hand out to touch something, how did the hand stop where you wanted it to? Feedback, by various paths, was a concept that fitted all the observed facts. It simplified explanations; it predicted results. The idea that something caused by the original action that opposed and controlled it was new and exciting.

I have two pocket calculators. One has a keyboard that clicks under finger pressure, like a typewriter key. The other keyboard has keys of the conductive plastic foam type. And be it ever so bounceless, I don't like it, because it feels just like stepping in a cow-clap. It is just mushy; the other keyboard lets my fingers know when to stop pressing, with a click that is felt as a vibration. Expecting this, I actually cracked the circuit board on which the mushy keys were mounted, trying to make them react as expected. I had to cement another board onto it to prevent breaking the printed connections.

Also, I worked for a time at a broadcasting station as a transmitter operator. The on-off buttons controlling the circuit breaker for the high voltage were of the industrial type. They were spring-loaded and all that, but had absolutely *no* follow at all. Everybody hated them – you couldn't tell anything by feel. They gave a disconcerting impression of *anticipating* you, as if they operated while you were only *thinking* about pushing them.

Ask any target shooter what a bad trigger pull will do to his scores.

The fact is that most of us are confused and uneasy when something doesn't "feel right." This applies to telegraph keys, too. The rigidity of the side-adjustment, the absence of side-play, dulls and reduces the feedback that monitors what flows out of our brain, down the arm to the fingers, and into the key. This is my theory. No one else has ever said that this is true, so far as I can find out – and I've tried! – if only because telegrapher's paralysis is as dead as its victims, for the most part. It is one of the rarest of diseases, *so far as telegraphing goes,* but it has other manifestations, and should, by all means, be understood.

We have to have feedback, lest the nerves rebel through confusion. I have seen a man

standing, back arched, face contorted, arm stiff, trying to telegraph by tapping. I didn't laugh. Telegraphing was part of his job, and for him it was torture. Of course, he could send like a streak with a bug. If you check the old ads, you will see that they claimed "ease" and "speed" as selling points. But bugs were and are very expensive – aside from a few broker operators, most sales were to telegraphers who had glass arms. They were as helpless without their bugs as a present day grammar school student without his pocket calculator.

Lyall Watson, in his book *Super Nature,* has some interesting things to say. He tells of experiments in 1946 in which Grey Walter and his colleagues used flashing lights during brain wave tests and their patients went into convulsions. Other workers have had similar results when the rate of flashing coincided with certain brain wave patterns. The most consistent seizures occurred when the brain waves themselves were made to trigger the light, something like a buzzer or multivibrator action. Under this arrangement, half of the patients had spasms. And they had no history of epilepsy! Watson also mentions a bicyclist who blacked out while riding down a lane with trees along its sides. When the sun was low enough, the flickering produced by riding past the line of trees was enough to cause blackout – not just once but several times. How many mysterious automobile accidents, do you suppose, are caused by something like this?

In 1927 I went to work for AT&T. I knew a little International Morse, not much, and I discovered that Morse was quite a lot different. It was faster, too, once you learned to read spaces between clicks instead of tone pulses.

There was a full telegraph department with a few printer circuits, but mostly hand-operated Morse. In the test room, where I worked, there were at least a dozen "test wires." These were simple Morse circuits with a sounder mounted high, well above the jack-fields, next to the carvings of "Nekkid Wimmen" which were standard decoration in those days. Now we got plastic strips. Down on the keyshelf in a clutter of switch-keys and cord-circuits and such, dwelt the telegraph keys. The clutter was not conducive to good sending, but we had men who could do it. For one thing, telephony was just something added to their Morse experience. They were operators; that is how they got their jobs. They learned how to operate a Wheatstone Bridge, and gain a repeater, and that was about it. The test wires were used for communication between offices.

In those days, a telephone route between cities was likely to have just one standard 40 wire line. Open wire, not cable. That meant 20 side circuits, ten phantoms, thirty phone circuits in all. The side circuits were all composited (a composite set was a low pass filter) and a telegraph wire – nearly always half-duplex – could be connected to each wire, giving forty telegraph wires, two way. That is where the name "and Telegraph" comes from. These did not carry public messages, by agreement with Western Union; they were all either leased wires, or test wires.

You had to be conscious of your own office call; when you heard it, you interrupted the circuit to "break" the distant operator. When you heard the wire close, you said "I" and listened to his first words. Invariably he wanted something simple, and, while he was telling you, you walked away and did the job, listening all the while. Then you came back a few seconds later and said OK. The most convenient system you ever saw; it took a lot of effort and determination for the High Brass to kill it. We liked it. Radio Traffic men are aiming at such operation with their "break-in."

I was just a kid then; my co-workers were 30 to 60 years old. The older men got bored when work was light and they weren't kidding me. Then they resorted to horseplay. A favorite gambit was to loosen the trunnions to the critical point so that when the key was touched, the lever would explode out of it like a mousetrap and the spring would be lost. The victim had to try sending with the switch-lever, by which the circuit was kept closed while idle. This is like telegraphing with a knife-switch, and he would swear loudly to the delight of the perpetrators.

As I say, I was young. This did not suit my sense of propriety. Besides, I had noticed that, even when in working condition, the adjustment was very sloppy. So to be helpful I would tighten them to what I thought was the "proper" adjustment. In other words, I was a wise guy, just as the kids are today, and for the same reason: ignorance.

My "adjustment" never lasted long, so one day I took a pair of gas-pliers and tightened all the lock nuts. And then it really hit the fan. Grown men running up and down and cursing and threatening mayhem and worse for the unspeakable scoundrel who not only messed up all the key adjustments but had the unutterable gall to LOCK them that way! I watched them searching behind the test-board and under the duplex tables and even up on the cable racks for the dastard, whoever he might be, while I was in plain sight and feeling a little exposed. I knew who it was, all right. It was me. I was dimly aware that I was being taught something, and with more tact and good humor than I deserved. Later I, too, put on a show of rage and incipient insanity when, as a chief, I had to make a point! You can't do it often, but it works, it works! The difficulty is in keeping your face straight.

I asked one of the older men, who had been patient with me, what it was all about. "Don't you know? Send on a key without side-play and you get a glass arm!"

My informant was one of the few, even in that office at that time, who knew what caused Telegrapher's Paralysis; he knew that it was due to bad key adjustment and "nerves," and that was as much as anyone knew. In the years since, I have asked questions at every opportunity and so far have had not one answer that means anything. I have puzzled over it for those same years, and the work of Norbert Weiner and others gave me my first clue. It is entirely possible that I am the only man alive who actually does know; I hope not, and would be delighted to hear from anyone else who does. But I am afraid that, until now, I have been a torch bearer.

This story will undoubtedly be classified under Dewey Decimal System in some library or other, and will still be obscure. However, it will be in print, and not locked up in the heads of dead men. The knowledge, aside from help to key men, might even furnish an important clue to the psychologists and other workers in the field.

Be that as it may, you have no excuse for acquiring a glass arm. You know better. ■

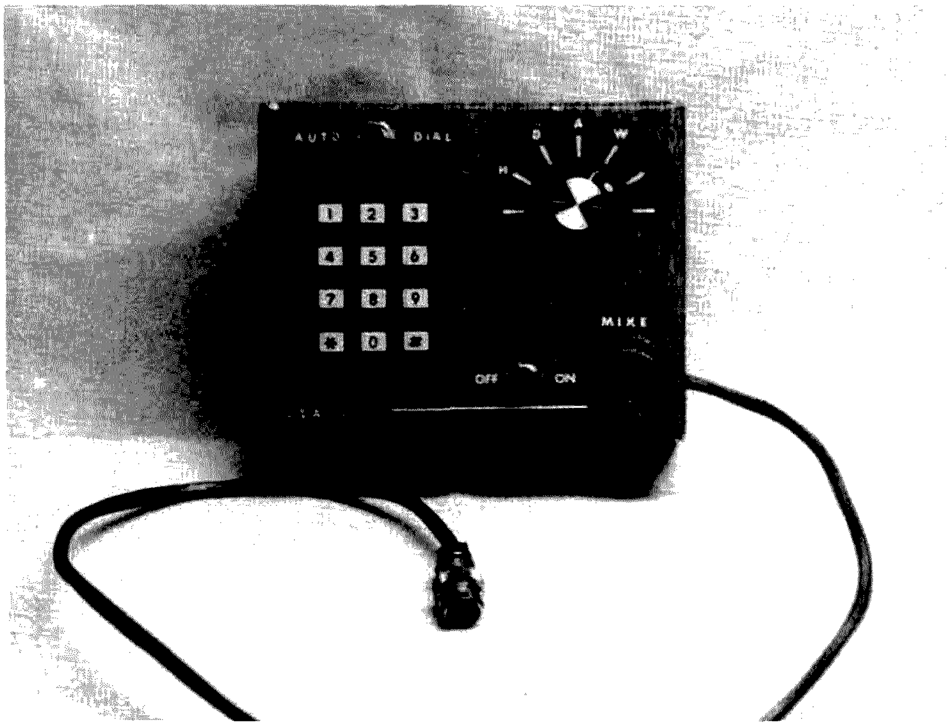
Mobile Autodialer

-- six preprogrammed numbers

Most of us seem to dial 4 or 5 numbers most often when using autopatch. And it always seems you decide to make that important call when you're up to your ... ah ... bumper ... in traffic. This situation, and a near miss on the expressway, is why I felt the need for the WB9LTA autodialer — and, of course, the never ending "need" for a new gimmick.

The features of this autodialer are: rapid, error-free dialing of any one of 6 preprogrammed phone numbers; automatic transmitter keying; simple operation — set the rotary switch and push the activation button; optional keyboard for unprogrammed numbers; optional acoustic coupling; and rock stable touchtone generator, requiring no tuning.

The heart of the autodialer is a new McMos® chip from Motorola, the MC14410P. This is a 2 of 8 tone encoder, specifically designed for touchtone applications. It uses a 1 MHz crystal divided internally to generate the basic tones. It is accurate to ±½%, well within the specs required to key Bell TT



Front panel; PC board, top view.

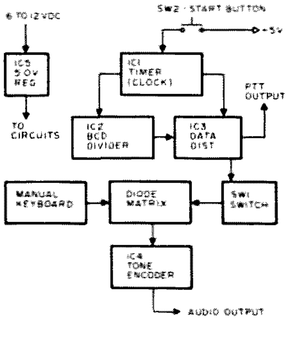


Fig. 1. Block diagram.

circuits. To achieve the sequential dialing necessary to dial a phone number, a 1 of 16 data distributor stepped by a BCD decimal counter was chosen. A NE555 timer was chosen to provide the clocking for the circuit.

The only really critical parts of the circuit are the tone frequencies, which are controlled by the MC14410 and the crystal; the digit pulsing rate, which is controlled by the 555 and R2; and the interdigit time, which is controlled by the programming of the outputs of the 74154. A note regarding the digit and interdigit timing: Bell specs call for a 75 msec tone pulse, separated by a 25 msec interdigit space (worst case specs), to reliably access Bell equipment. Some offices may respond to faster pulsing, but not all will. This circuit is designed to fit these specs, with some "security hedge" built in.

How It Works

First, a word of explanation: I am not an engineer. I look on ICs as "little black boxes." I don't understand how many of them work, or what's in them. All I care about is what can be done with them, and how to wire them together to make them do the job you want done. Don Lancaster's book, "The TTL Cookbook," has been a great help here. But just plain "trial and error" has been my best teacher. With that, here goes an explanation of how this device works (refer to Fig. 1).

When you push the start button, IC1 starts. IC1 is wired as an astable multivibrator, with the frequency controlled by R2 and C2. The output of IC1 is fed to IC2. IC2 is a decimal divider which puts out a BCD sequencing code at the rate dictated by IC1. The BCD outputs of IC2 are applied to the inputs of IC3, a 1 of 16 data distributor. The outputs of IC3 will be brought to logic 0, one at a time, then will go back to logic 1. The rate at which this happens is controlled by the clock (IC1). Which outputs change is controlled by IC2. The outputs of IC3 are routed through switch 1 to control which digit tones are applied to the audio output at any given time. Note that only every other output of IC3 is used; this provides for the interdigit timing (which is equal to the digit timing). Switch 1 is the programming device. It controls the sequence in which the numbers are dialed, and which numbers are dialed. The diodes on the inputs of IC4 and the outputs of IC3 connect (by jumpers) to switch 1, and form the programming matrix. IC4 is the tone generator. It has seven inputs, which correspond to the seven basic touchtones. When a low tone input and a high tone input are brought to ground simultaneously, a TT digit is generated. See Table 1 for which inputs generate which digits.

The high group and low group outputs are combined through isolating resistors to give the digit output. The digit output is coupled to the rig through the coupling cap, C7. R6 controls the output level. If acoustic coupling is desired, the optional amplifier consisting of Q2 and Q3 is used, and is direct fed from the level control pot (R6). C7 is not used in this application.

PTT control is achieved by applying the pulse at IC3, pin 16 to the base of switching transistor Q1. The collector of Q1 provides a ground path to activate the PTT circuit in most rigs when Q1 is biased on. If your rig uses a positive voltage, or diode switching to activate the PTT, then you will have to use the optional circuit shown.

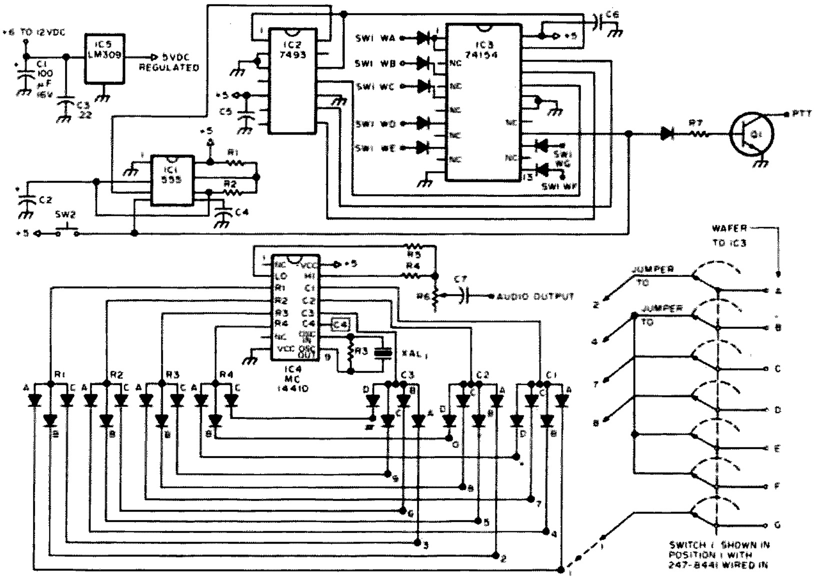

Fig. 2. Schematic.

Construction

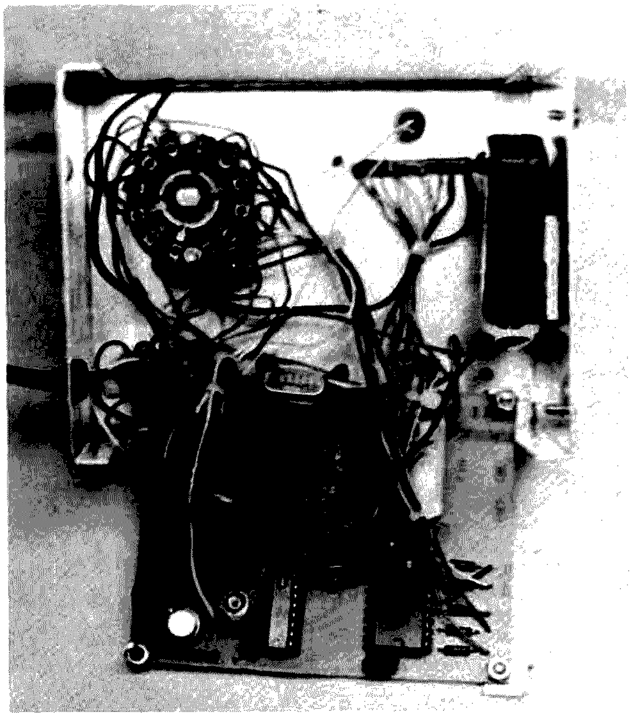
Parts procurement may be a problem in some cases, especially in obtaining IC4, its associated crystal and SW1. Sources for these parts are provided in the parts list. The optional tone pad is also a problem, and again, sources are in the parts list.

A PC board is the most desirable way to build this project, and a layout is provided. Etched boards are also available. A vectorboard could be used, but the number of diodes in the matrix may make the final device unreliable unless you epoxy the diodes to avoid movement.

Assembly is straightforward, with no special precautions needed except in handling IC4. Since it is a CMOS device, it is subject to damage from static electricity. Do not remove it from its carrier until you are ready to insert it into the circuit. At that time, you should run a strap from your wrist to an earth ground, to bleed off any static buildup on your hand. DO NOT touch anything electrical in your shack while you are grounded. If you work on a wood, concrete, or tile floor and wear rubbersoled shoes and cotton clothes, static buildup is unlikely, and you needn't ground yourself.

Wiring the jumpers in the diode matrix requires some care, to be sure the correct digit tones will be generated. Refer to Table 2 for these connections.

To simplify construction, program the individual phone



PC board, bottom view; internal wiring view.

Table 2. Diode Matrix Jumpering.

numbers on switch 1 before wiring the jumpers from IC3 and from the diode matrix to it. When programming SW1, avoid confusion by labeling the various wafers of the switch with A through G. "A" corresponds to the first digit of the phone number and to the point on the diode matrix to which it will be attached. "B" corresponds to the second, etc. The wiper for wafer "A" will connect to diode "A" on the board, etc. Position 1 on each wafer will be used to program the first phone number, position 2, the second, and so on. Refer to Table 3 for an example of programming. Note that any digit is only brought from the diode matrix to the switch once. Whenever that digit is needed in programming again, simply jumper it from another point on the switch which represents the same digit. In the example shown in Table 3, the digit "4" was brought to switch 1, wafer B, position 1 from the diode matrix. Then jumpers were used from wafer B, position 1 to wafer E, position 1, and from wafer E, position 1 to wafer F, position 1 to wafer G, position 2.

After the phone numbers are programmed on the switch, then bring the jumpers from the diode matrix to the necessary digit and wiper points on SW1. Now, recheck the programming for errors. Trace from the R positions on IC4 to the C positions to verify the correct tones as shown in Table 2, then trace the wiring through SW1 to verify that the correct phone numbers exist in each position. This should complete the switch programming.

If a keyboard is used, jumper from each digit on the diode matrix to the correct pin on the keyboard, referring to Fig. 3 for the pinout on the specified keyboard. Other keyboards may be used, but they should provide a common contact on each digit, and an isolated contact for each digit. A multiplexed board will work, but it still must have a common contact for ground in each digit. A 16 digit keyboard may be used, but diodes are not included in the matrix, and would have to be added.

It is suggested that sockets or molex type pins be used on all ICs. Also, use a good grade capacitor for C1 and C2, and a 5% resistor for R2, 4, and 5. Other part values are not critical.

Testing

Prior to testing, double-check all wiring — ICs are great till you apply voltage to the wrong point! Also recheck the PC board for hairline trace bridges, or solder bridges; I had 3 solder bridges on my prototype.

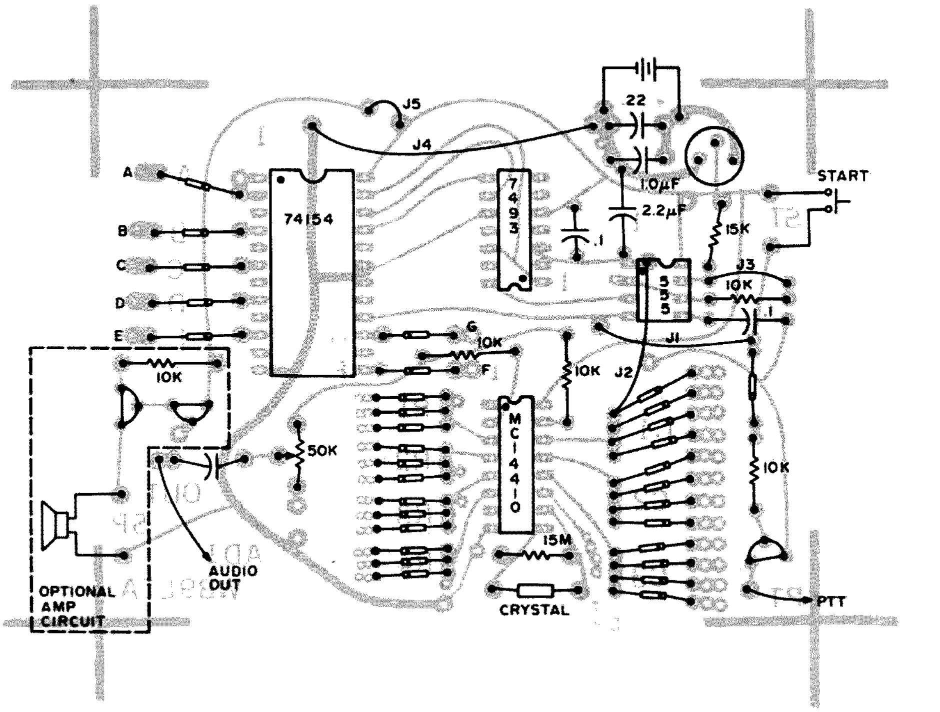

Fig. 6. Component layout (full size).

Once satisfied with the wiring, apply voltage, using a 9 volt transistor battery or a 12 volt power supply. Attach a voltmeter to the output of the LM309H and check for 4.5 – 5.5 V dc. If voltage is above or below these limits, remove power and recheck wiring; if the voltage was more than 1 volt above the 5.5 volt level, you may have damaged one or more of the chips. If the voltage was too low, check the LED, then the chips. Of course, don't overlook the LM309H. If it was inserted incorrectly, it will probably be damaged. One other word of caution: NOTE that the 7493 is inserted with pin 1 down toward the MC14410, just opposite of the rest of the chips.

Assuming that the voltages are OK, the next step is to check the tones. I used a small transistor amplifier, connected to the output capacitor, to listen to the tones. When you push the start button, you should hear a burst of tones. If not, you may have a wiring error, or poor connection. Next, test the tone chip by attaching a jumper to ground, then touching the unattached clip to each of the R and C pins on IC4. If you get tones, next touch the clip to the TT digit output (the outputs that go to SW1). Again, you should hear tones. One way to verify the accuracy of the tones is to use a touchtone phone. Listen in the earpiece while pressing the same digit on the telephone and the autodialer – you should hear a beat effect, which tells you that the two are close.

If all of this testing proves the unit is working, you should check the PTT transistor Q1. Clip an ohmmeter between ground and the collector: When the start button is pushed, the ohmmeter should show a low resistance reading (10-60 Ohms). If all of this works, your autodialer should work. Attach it to your rig and try it!

If the unit does not give a tone burst when the start button is pushed, but the tone generator is working, the problem most likely is in the 555. Recheck the wiring around it, and the timing components, C2 and R2. If a scope is available, check pin 3 for an output pulse. I have encountered a few defective 555s obtained surplus, so this may be a consideration.

If the unit dials too fast or too slow, C2 or R2 are of incorrect value. Cheap capaci-

Table 3. Example of SW1 Wiring.

tors are rarely close to the stated value, so if you bought an inexpensive unit, that may be your problem.

One helpful test fact: The current draw of this circuit is about 100 mA. If trouble occurs, this would be an important thing to check. Higher current indicates a potential short (probably on the board), while lower current indicates a potential open (probably a poor solder joint).

The final item to check is the numbers your autodialer is dialing. If it dials an incorrect number, you've made a mistake in your switch programming.

Operation

Operation is simple: Apply the power, select the number to be dialed with SW1, and push the start button. Presto, you have your party!

A few notes are in order. When power is applied to the unit, the dialer will sequence, then stop, so avoid turning the unit on where it might interfere with a QSO. If you choose a 9 volt transistor battery as your power source, use a mercury or nicad cell, as an alkaline or carbon-zinc cell will cease to operate in extremely low or high temperature. The best source of power is your car battery. If your dialer malfunctions, it is most likely the power supply. If you get unreliable dialing, the problem is probably one of excessive speed. Adjust R2 upward in value. If the audio output is too low, it may be necessary to adjust the value of R4 and R5. Do not go below 1k Ohm for these resistors, however. If you still don't have enough audio to drive your rig, you may need to add the optional amplifier. Another problem area was recently brought to my attention: Some rigs are using audio circuits which provide base attenuation. In these circuits, it may be necessary to juggle the values of R4 and R5, maybe such as 1.5k for R5 and 1.0k for R4. DO NOT juggle these values unless you find (with a scope) that the high and low tone groups are more than 4 dB apart in level.

Finally, select an enclosure for your autodialer. I used a 3 x 4 x 5 inch minibox because it is inexpensive. I covered it with contact paper, then marked it with Datak dri-transfers. You may wish to go with a more deluxe enclosure, such as a LMB442 or a sloped panel box. I do recommend a metal enclosure.

Hookup to your rig may be accomplished any number of ways. In my unit, I used a jack identical to that used on my TR-22, mounted on the front panel of my autodialer. I attached a short length of 3 conductor cable from the common, audio-output, and PTT outputs of the autodialer, to a plug to match the jack. I then plugged my mike into the autodialer, and plugged the autodialer into my rig. You could put an accessory plug (some rigs already have one) on the back, and feed the PTT, common, and audio to the rig this way.

I would like to give credit to K9OMS, who spurred this idea by building an autodialer some time ago, proving to me that the basic idea was sound. I would also like to thank WB9SFF, WB9PAR and K9JRI for their technical assistance in developing the final product. Finally, the XYL deserves a lot of praise for her tolerance of my time spent in the shack working on this project. ■

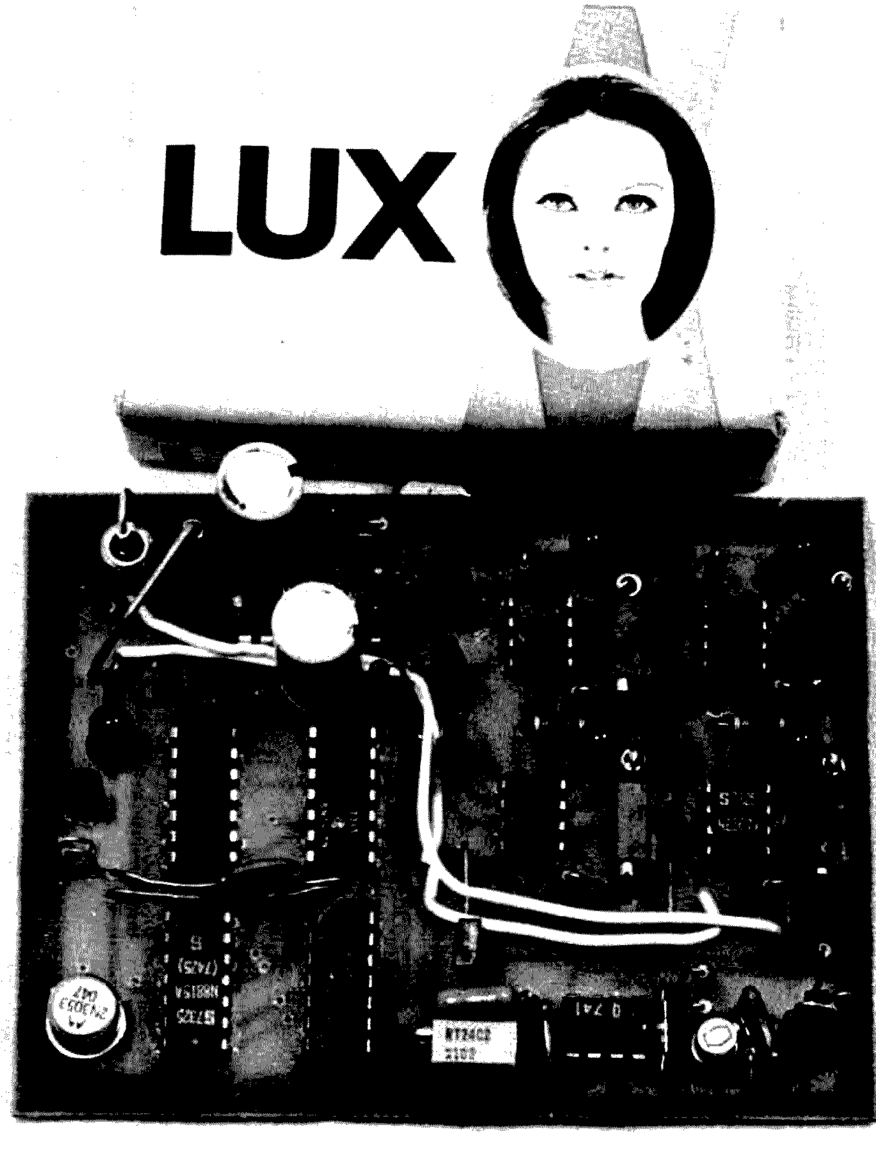
Autocall '76

--using a touchtone decoder

C. W. Andreasen WA6JMM
PO Box 8306
Van Nuys CA 91406



The purpose of this circuit is to allow the user to monitor a radio channel without having to listen to constant chatter, and yet be available for call. This unit may be used with any radio, and will work on any simplex or repeater channel the radio is tuned to. The circuit uses no special hard to get coils, or other rare parts, and is easy to tune and set up. As shown, the unit will respond to a three digit Touchtone code, but with minor changes the unit can be made to respond to any number of digits.

When the operator wishes to use the device, the audio input plug is inserted into the external speaker jack provided on most radios. The unit will monitor the channel for the programmed series of Touchtone numbers in the proper order, during a predetermined "window" of

The Touchtone sequence decoder. A zener diode and resistor may be used in place of LM309. Zener type 1N751 and resistor value of 68Ω, 2 Watts are suggested. Undrilled PC boards are available from the author for \$3.50 each.

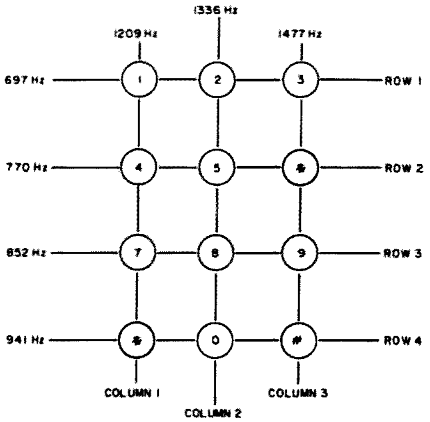


Fig. 1. Touchtone pad frequencies.

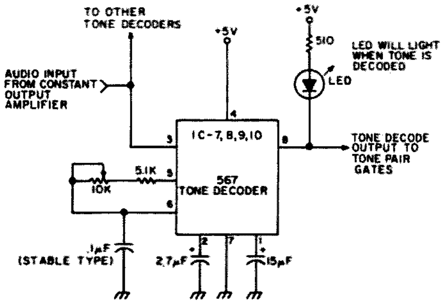

Fig. 3. Tone decoder using 567. Circuit repeated four times.

time (all three digits must be received during a measured time period). When the proper three digit code is detected, a latch will set, enabling a light which shows that the unit has been paged, and also enables a transistor which can key a buzzer, fire a cannon, or even key a relay turning on a speaker letting you hear the channel and your call. This key will time out after five to ten seconds, depending on values used, while the light will remain lit until reset manually.

Circuit Description

The audio goes into a constant output amplifier (Fig. 2). This amplifier will provide a constant output level to the tone encoders even though the input level may vary over a range of 50 mV to more than 6 volts. This constant level audio is distributed to four 567 tone decoders (more could be added). Each tone decoder is tuned to detect one tone in the Touchtone matrix, which has seven tones, of which we only use four. Under normal conditions, two decoders would be tuned to the columns, and two to the rows (refer to Fig. 1). The output of each decoder is fed into gating (IC1) where the tone pairs are determined. The output of each tone pair gate is a digit decode (example, column 1 and row 1 = digit 1). These four decoded numbers go both to the sequence logic and an "OR" gate which triggers a oneshot (Fig. 4). This oneshot will trigger any time a number is decoded, and will enable the sequence logic for a time period, forming a window, which resets the logic when time-out occurs.

The sequence logic is simply three flip flops which can be set only in the wired, predetermined order. This may be wired by using three of the four decoded numbers connected to the proper gate in the desired order. An example would be: if I decode columns 1 and 3, and rows 1 and 4, my four decoded tone pairs, or digits, would be 1,3,*, and #. If I were to wire the decoded number 1 to pin 9 of IC2, the decoded number 3 to pin 9 of IC3, and the decoded symbol

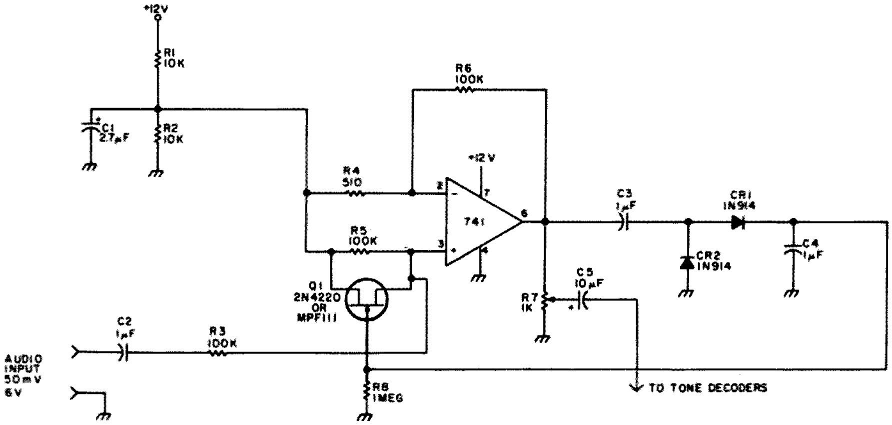

Fig. 2. Constant level audio amplifier.

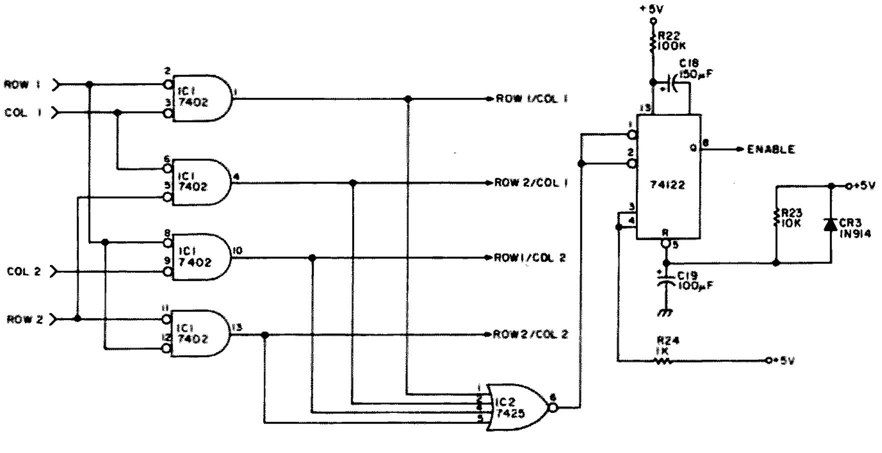

Fig. 4. Tone pair decode, window enable.

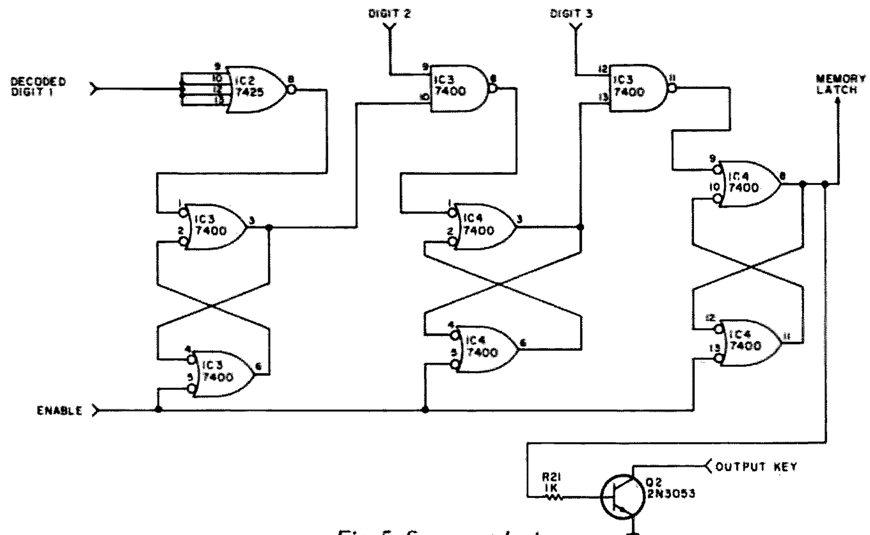

Fig. 5. Sequence logic.

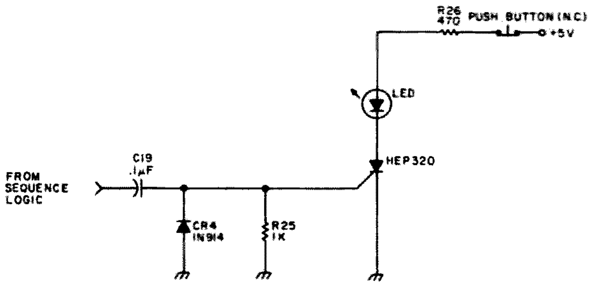

Fig. 6. Memory latch.

to pin 12 of IC3 (Fig. 5), my unit would respond to the call of 1-3-#. As you can see, the fourth decoded digit is not used. If the builder wishes to expand his call to four digits, this can be done by the addition of another flip flop and gate wired onto the end of the sequence logic chain.

When the proper code is received, the memory latch (Fig. 6) will set, until reset by the user, and the output key will turn on for a period of time which will end when the window times out and the unit resets, in about five seconds with the values shown.

Tuning

To set the tone decoders for the desired decode, connect the input of the sequence decoder to a Touchtone signal source. After adjusting R7, the output of the constant level amplifier, so as to drive the tone decoders with about 100 mV of audio, pick the first column to be decoded and generate this tone (if using a Touchtone pad, hold two keys in desired column simultaneously, and this will provide the tone for that column; the same holds true for the rows). Adjust the tuning resistor on the 567 tone decoder desired, until the LED in its output lights. Move to another 567 decoder and repeat this same procedure with the second column, and then repeat again for each row. With the outputs of the tone decoders wired to the pair gates as shown, each of the four gates will have a HIGH output corresponding to its tone pair input. The unit is now set up to recognize four tone pairs, of which the order of recognition is determined by the wired order to the sequence logic.

The unit built by the author has been in use for some time and is constantly connected to the audio output of the receiver. The unit has proved to be stable and reliable, decoding the tones even while the incoming signal is noisy or the person sending is talking on top of the tones. My unit has *never* falsely gone off due to voice or noise on the channel. ■

Build This Lab Type Bridge

-- and measure transformer impedances

Arny Cain WB4FDQ
2306 So. Ruffner Rd.
Melbourne FL 32901

Hold it! Don't let the title scare you away. This is not an article written strictly for engineer types, but just the opposite. Considering the fact that I have been playing with electronics (we used to call it just plain radio) since 1933 and only just discovered Ohm's Law about eight years ago, you may understand that I am far from academic-minded. As a matter of fact, I was never graduated from high school and only got a college degree in 1973, but that is another story. Truth to tell, I have always been one of that vast army of cut and try chaps who are scared silly at anything that even remotely resembles an algebraic formula. This is also the reason, indirectly, that I built this valuable tool and worked out my own cut and try method of solving a nagging, typical ham problem.

It all started back in the mid-60's when I was building the modulator for a two meter rig. I needed a transformer of a specific input and output impedance, in Ohms of course. Since I had (and still have) about a hundred transformers (all unmarked, of course) lying around, and since at that period of history I was working at the Space Center at Cape Canaveral, it

was no trick at all to take a few likely-looking prospects into one of the many electronic labs. Telling my problem to a group of sympathetic, highly trained, and highly paid engineers brought instant cooperation. Unfortunately, sophisticated labs not withstanding, several hours later we still did not know the impedance of any of the transformers. Greatly disappointed, I gathered up my "boat anchors" and decided that there must be an easier way. I finally bought the proper modulation transformer and got the rig on the air, but in the back of my mind the determination to find an easy way out of this dilemma remained.

Well guys, after an interval of about ten years, here is the simple solution. Three pieces of equipment are needed, two of which you probably have. The first is a signal source at about a thousand cycles (you can use sixty cycles in a pinch), since I understand that most audio transformers are measured at this frequency. The source should have an output of about five to ten volts, although it can be less if you use a sensitive oscilloscope for the null detector, which is the next piece of gear that you need. You can use a VTVM, a scope, a simple old 6E5 magic eye null detector, or (if you have enough signal) an ac micro-ammeter (not recommended). The third and last thing that you will need is (the reason for this article) an instrument improperly called a Wheatstone Bridge.

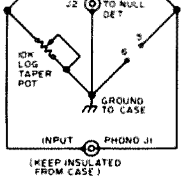

Fig. 1. Schematic.

Please don't rush for your pen to defend old Sir Charles Wheatstone. I'm not trying to deprive him of his place in history, but the fact is that he just didn't invent the darn thing. True, he publicized it, but the device was invented by an English scientist named Samuel H. Christie in 1833. At any rate, this simple piece of gear is the solution (I'll explain how I used it to beat the unknown transformer problem in a moment) to not only the above problem, but to so many others on the workbench that I now wonder how I ever survived in this hobby without it. Considering its simplicity (see schematic), it is perhaps the most valuable instrument that I own.

Now for the construction data, which will be meager because no one will build a carbon copy anyway. First, don't use a standard volume control for your calibrated pot. They are just too small to permit any degree of accuracy and/or resettability. As you will observe in the photos, the potentiometer that I used is a 5½" diameter, wire wound, 10k Ohm log taper job made by the Muter Company and, I believe, long since discontinued. I've had mine for about 6 or 8 years and I think that I bought it by mail from one of the surplus houses that advertise in *73*. I do remember that I paid $3.95 for it and it's probably worth ten times that. You don't have to have one that big, but try to get a pot over two inches in diameter.

Wire with heavy leads, the heavier the better (I used number 14 wire), and make sure that you use well-insulated binding posts. One more thing, before I forget: Be sure that your signal input connector is well insulated from the chassis. As you can see in the photos, my plug-in

Table 1. Resistance Measurements.

resistor jacks are made using banana plugs on pieces of Lucite. The reason for the funny shape (the Lucite) is that I had a bunch of three prong connectors from a long since defunct grid dipper. All I had to do was to remove one banana plug; ergo, funny looking jacks. The only other components that you will need are some precision resistors and capacitors, preferably 1% (see list). The accuracy of the instrument depends on two things: the precision with which you calibrate your dial, and the accuracy of the standard resistors and capacitors that you use.

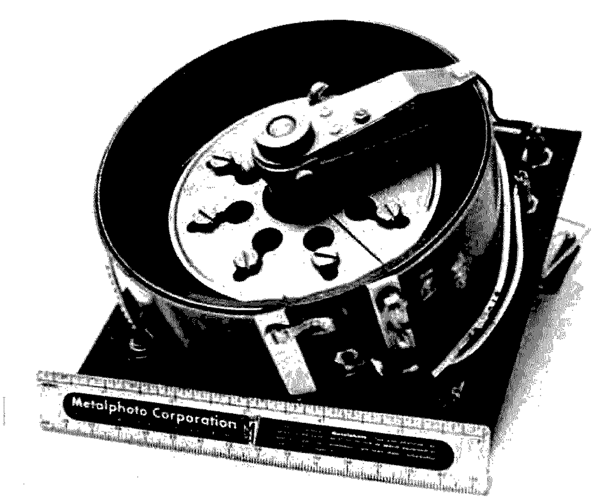
I made my dial six inches in diameter using a large skirt knob and a flange from a daylight load spool from 16mm movie film. I filed a flat on the shaft of the pot so that the dial would never slip and would retain its calibration if it should ever have to be removed. After the instrument was assembled I sat down with a handful of precision resistors and my VOM

to calibrate. I hooked my ohmmeter across terminals #1 and #6 and marked the dial carefully with a pencil, checking every reading against a known 1% precision resistor wherever possible. Later I applied white press-on numbers and dots and sprayed them with clear lacquer to protect them. The calibration procedure is not difficult, just tedious. Calibrate the major 1k Ohm points first and then the 100 or 200 points in between. The more careful you are, the more accurate your bridge will be.

As you will note in the photographs, I used standard RCA phono jacks for input and output. I use them whenever possible on my projects because of the wide variety of shielded cables available that match them. The case is 6"x6"x6", formerly black crackle finished, salvaged from my junk box (the whole garage), and resprayed red to cover the chips and rust spots.

Just one more thing on construction before we get to the good part. If I were to rebuild mine I would space my banana plug posts a standard ¾" apart; that way I could use standard dual banana jack instrument plugs. It doesn't affect anything; it's just a matter of looks. My Lucite plugs look rotten and it bugs me.

After I had completed the bridge I spent a couple of hours playing with it. I found it difficult to believe that such a simple device really worked so well. Finally I picked up an audio transformer with known impedances, and hooking one winding across the bridge and the output of my audio oscillator (set at 1 kHz) to the input, I adjusted the scope for a nice one inch trace. Try as I might, I could not get a reading anywhere near the impedance marked (in this case 10k Ohms). It suddenly occurred to me that the other winding should be loaded to its proper impedance in order to get an accurate reading on the winding under test. I quickly hooked up a four Ohm resistor to the output winding and, lo and behold, measured 10k Ohms on the primary. I then got myself a cup of coffee and sat down to do a little skull work.



As I sat sipping and pondering, it suddenly occurred to me that since four Ohms is a pretty low resistance, what would happen to the impedance of the other winding if I were to short the four Ohm winding? To think is to act, and I now measured approximately 1800 Ohms across the primary. Could it be that shorting the low impedance winding gives you a reading of about one fifth of the true impedance? Subsequent tests with other transformers show that, although this is not one hundred percent accurate, as a general rule of thumb you might use this as a ball park figure to start. Here is the procedure that I finally worked out.

Start by measuring the dc resistance of all windings with an ohmmeter (or with the bridge using the described procedure for dc resistance measurements) and marking them. If you are sure that it is an output transformer, hook a 4 or 5 Ohm resistor across the lowest resistance output winding. Connect the high resistance winding across the #5 and #6 terminals of the bridge, a 1 kHz signal to the input, and a suitable detector to the output. Measure the resistance and hook a carbon resistor of *this* value across the winding you have just measured. Reverse the transformer and measure the previously shunted low impedance winding. If it was an output transformer and you had used the 4-5 Ohm shunt, you will probably find that you are within 5-7% of the true value of the transformer. Close enough for all practical purposes.

If you are not sure of the type of transformer you are working with, proceed as follows. Short the leads of the lowest resistance winding together and connect the highest resistance winding across the bridge. Measure and multiply the reading you get by six and connect a resistance of that value across the winding that you just measured. Now reverse the transformer, measure the previously shorted winding, connect a resistor of that value across it, and repeat the procedure on the high impedance winding. It doesn't take but about two or three measurements, going back and forth from one winding to another, to achieve a remarkable degree of accuracy. Practice on a few transformers of known value and if you find your readings coming out wrong, look for shorted clip leads or open connections. With a little practice and care you can solve your unknown transformer problems.

Table 3. Capacitance Measurements.

It will interest you to know that you can also measure carbon and wire wound resistors to a very high degree of accuracy using dc current. First connect a source of dc, a battery or other supply of from 1½ to 4½ volts to the input jack with a push-button in series, and a 0-50 or 0-100 dc center scale micro-ammeter to the output jack. Hook the standards and the unknown up in accordance with the resistance chart. Using the push-button for momentary contact, start rotating the dial until you start to get a null, after which you can hold the button down to finalize the null.

Using an audio oscillator you can also measure capacitance and inductance as well as resistance. I've included the charts for these measurements also. Just remember to keep all test leads as short as possible, make tight connections, and be careful of shorts and open connections. For those of you who want to get involved in the more esoteric and/or mathematical use of this instrument, your public library has more than one engineering manual that will give you the dope on such elegant things as finding the power factor of capacitors, etc.

As for me, I just hook 'em up using the charts, tune for the best null I can get, and I'm happy with the results; but of course I'm just an old cut and try type. Try it; you'll like it. ■

How Those Triangle Things Work

--a sort of op amp handbook

Definition of operational amplifier: one that works, as opposed to a non-operational amplifier; also known as that "triangle thing" on a schematic.

While not strictly accurate, the above definition is as good as any. While most of you have the idea that this triangular symbol represents some kind of amplifier, you may not be aware of how this thing called an op amp does its job. While, like any other amplifier, the function of an op amp is to create a large signal from a small one, the op amp has some special characteristics that need to be known in order to use it. With proper connections the op amp can become an amplifier of stable gain, an integrator, a voltage comparator, or function in almost any other way you can imagine (or glean from the application notes). The heart of all these things is an almost perfect, slightly temperamental but versatile building block.

Before we take a look at the real device, it might be interesting to look at a perfect amplifier. We'll start at the input. One of the most versatile input structures for an amplifier is the differential input. This has the ability to select those signals which appear different at each input while rejecting those signals that appear the same at each input. So the perfect amplifier has two inputs. Also, since the amplifier shouldn't load the preceding stage, the input impedance must be high. Since this is an imaginary amplifier we might as well make input impedance infinite.

Next, what about gain? Since we never know how much gain will be needed in a given application, an infinite gain amplifier should cover all possibilities. You might think that infinite gain would be difficult to control but, as you will see later, the gain can easily be modified by external circuitry. The next item to be considered is output impedance. In order to make sure the amplifier can drive any load, output impedance should be zero. And lastly, the amplifier output should respond instantaneously to any change in the input signal. This means that the bandwidth has to be infinite and the phase shift through the amplifier has to be zero. Our perfect amplifier is shown in Fig. 1.

As you have probably figured, real life operational amplifiers are not quite as perfect. Let's take as an example the UA709. Like our perfect amplifier, the 709 has two differential inputs: inverting and non-inverting. Input impedance is not quite infinite. In fact it is only about 250k Ohms. The voltage gain of this amplifier is quite high – somewhere around 50,000. To get 1 volt of signal output only 20 uV of input signal is needed. Output Z is in the order of 150 Ohms. The bandwidth of the amplifier is limited by internal circuit reactance to 1 to 2 MHz (Fig. 1).

It almost seems a little disappointing that the 709 turns out to be so far from ideal. Actually, the 709 is a fairly average op amp. Some devices approach the ideal more closely and some are worse. The reason the perfect amplifier was introduced was not to make all the real ones look bad, but to serve as a design model for all amplifiers. In most cases a real (imperfect) amplifier is treated as if it were perfect (see later).

Operational Amplifier Specifications

There are several specifications that are important to operational amplifiers. The first, A_{VOL}, has already been mentioned. This refers to the open loop or unmodified voltage gain of the amplifier. If you're looking over the specs of several amplifiers, you'll find that this specification usually is around 90 to 100 dB (30,000 to 100,000). In most applications the exact value is not important. What is important is that the gain is high.

Another important characteristic of op amps is their ability to reject signals that appear at both inputs at once. Remember with differential inputs the idea is to amplify the *difference* between the signals present at the two inputs. Any equal signals such as

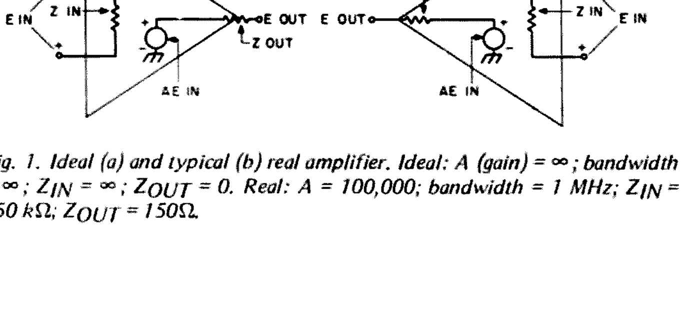

Fig. 1. Ideal (a) and typical (b) real amplifier. Ideal: A (gain) = ∞; bandwidth = ∞; Z_{IN} = ∞; Z_{OUT} = 0. Real: A = 100,000; bandwidth = 1 MHz; Z_{IN} = 250 kΩ; Z_{OUT} = 150Ω.

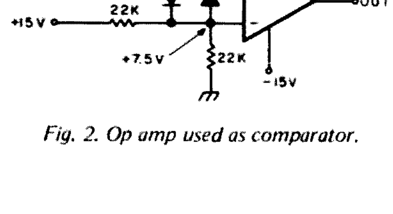

Fig. 2. Op amp used as comparator.

noise, hum or dc bias should have no effect on the output. The ability to reject these common signals is known as the common mode rejection ratio (CMRR) and is usually expressed in dB. It is simply the ratio of common signal to differential signal required to give the same output in either case. Most IC op amps achieve a CMRR of about 90 dB. This means that, in an open loop condition, if A_{VOL} is also 90 dB, differential signals will be amplified by 90 dB while common signals will be effectively amplified by only 0 dB (1). Like A_{VOL}, CMRR is very high in the typical op amp and can be treated in most cases as if it were perfect.

Let's shift away from the entire amplifier and take a look at the inputs of the common operational amplifier. Remember that the inputs of the mythical perfect amplifier were of infinite impedance. Of course the real amplifier doesn't quite make it. What's worse, the inputs are the bases of 2 separate (and therefore slightly different) transistors. A small but finite current must be injected into the bases of these transistors in order to turn them on. This current is, of course, called input bias current. And since the input transistors are slightly different, differing amounts of current are needed by each transistor to give the same effect. This current difference is known as offset current. Another type of offset occurs because of a slightly different reference level at each input. This is a voltage offset and in many op amps provision is made to adjust this out. In any case these offsets are small (typically 100 mA and 2 mV respectively) and are only of consequence when the amplifier is used in low input level situations. In situations where the input level is high in relation to the offsets, their effect is insignificant. But it should be recognized that those offsets exist and if the amplifier is to be expected to respond to low level signals, they must be dealt with.

As you probably are aware, not too many IC op amps perform well as 432 MHz amplifiers. As a matter of fact, most operational amplifiers are limited to an absolute maximum frequency of around 1 MHz. Some are not even good for high gain use as a hi-fi audio amplifier. This limitation is generally due to parasitic capacitance between circuit elements on the IC chip. Another more severe limitation is due to internal frequency compensation (see later).

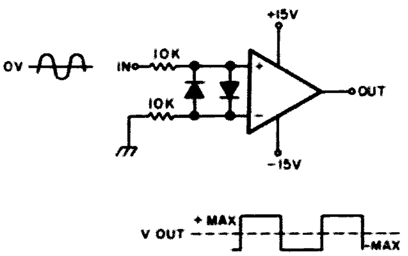

Fig. 3. 0 crossing detector.

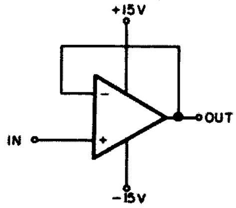

Fig. 4. Voltage follower.

$V_{IN} = V_{OUT}$.

Whatever the cause, op amps do not make good rf amplifiers, so their use is limited to the high audio range.

There are two bandwidth-related specifications that concern these amplifiers. The first is usually given in a graph as device gain versus frequency. The gain is usually flat from dc to some frequency at which point it starts to fall. The frequency at which the gain has dropped to 0 dB is called the unity gain crossover. At frequencies above this point the op amp becomes a very complicated and not too predictable resistor. The range between the start of fall off and the unity gain crossover is important to the stability of the amplifier and will be covered more fully later.

The other bandwidth-related specification deals with the ability of the output to change level rapidly. This is termed the slew rate and is given in V/uS. The higher the value of this specification, the faster the output voltage can change. You can see that since higher frequency signals change faster than those of low frequencies, the amplifier is less able to reproduce the high frequencies at high amplitude. The effect of slew rate is to make the bandwidth appear higher at low output levels than at high levels. This is not too great a problem unless you're trying to use the op amp as a power amplifier near its upper frequency limit.

How To Use 'Em

After going through the preceding section and learning how non-perfect IC op amps are, we are going to turn around and use them as if they were perfect. The why of the matter is two-fold. First (and most important), the IC is so close to perfect that the difference doesn't matter much. As an example, if we construct a voltage follower with a perfect amplifier (infinite gain) we would get 1.00000 . . . V out with 1.00000 . . . V input. With our non-perfect amplifier (gain = 100,000) 1.00000 . . . V input gives 0.999990 V out. That is only .001% error. Not bad, I would say. The second reason for calling our amplifier perfect is that circuit analysis becomes dirt simple.

Enough of this theoretical stuff. Let's see how these plastic (and/or metal) packages can be used.

One of the simplest ways to use the op amp is as a voltage comparator. With its high gain, a difference at the input of only a few millivolts produces full output. As shown in Fig. 2, a voltage divider (or a zener diode or

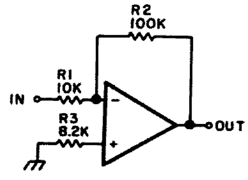

Fig. 5. Inverting amplifier.

$$\frac{V_{OUT}}{V_{IN}} = \frac{R2}{R1} = \frac{100k}{10k} = 10$$

some other stable voltage reference) places a fixed 7.5 V at the inverting input of the amplifier. Whenever the input voltage exceeds 7.5 V, the output swings to the positive limit. Whenever it is less than 7.5 V, the output swings to the negative limit. Of course the inverting and non-inverting inputs may be swapped if opposite output swings are desired. The only thing to remember is that the impedance seen by the two inputs should be about the same to minimize the effects of input bias current. This is desirable in any op amp circuit. The two diodes across the input only serve to limit the differential input. Some amplifiers behave strangely when their input becomes too great (like the inputs may self-destruct or the output may become the opposite of what it's supposed to or the output may latch in one state and forever thereafter ignore the input).

Another circuit (really the same circuit but used differently) is the squarer or 0 crossing detector (Fig. 3). Whenever the input waveform exceeds ground potential, the output swings giving a rectangular wave output no matter what kind of input signal is present.

That is about all that can be done with the operational amplifier without some form of feedback. By adding appropriate feedback, the amplifier can be made to do many chores. The main advantage of feedback amplifiers is that the characteristics are controlled by the feedback network – the characteristics of the amplifier itself have little effect. That's why the real life amplifier can be regarded as perfect – the differences are almost completely cancelled by feedback.

Feedback Amplifiers

The first circuit to be introduced in this group is known as a voltage follower (see Fig. 4). The actual function of this circuit is of an impedance transformer. It will take a signal from a high Z source and duplicate it at a much lower impedance. Since there are no components other than the operational amplifier, the design procedure is quite simple. Simply connect the output back to the inverting input. To find out approximately what those input and output impedances are, a couple of simple formulas are used.

For input impedance find the values for A_{VOL} and differential Z_{IN} in the spec sheet and stick them in this formula: $Z_{IN} = (Z_{IN,DIFF})(A_{VOL})$. For the 709 this works

out to about 11 G Ohms. (Yes, gigaohms!)

For Z_{OUT} find output resistance and A_{VOL} in the spec sheet and use this formula:

$$Z_{OUT} = \frac{R_{out}}{A_{VOL}}$$

Again, for the 709, this works out to 3 milliohms. Do not be misled by this figure. This low output impedance is only apparent if the current driving capabilities of the amplifier are not exceeded. If high current outputs are required, a power amplifier should be connected to the output *within* the feedback loop.

The best figures for the above occur where the gain is highest (0 Hz). Note that as the frequency goes up and A_{VOL} drops off, both Z_{IN} and Z_{OUT} become less ideal. But for only one component and thousands of megohms of input impedance it's a pretty good circuit.

The principle used in designing this and other feedback amplifiers is to regard the amplifier as perfect — that is, having infinite gain and infinite input impedance. If the amplifier has infinite gain the only way we can get a finite voltage at the output is with

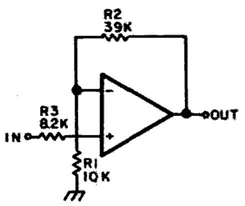

Fig. 6. Non-inverting amplifier.

$$\frac{V_{OUT}}{V_{IN}} = \frac{R1+R2}{R1} = \frac{10k+39k}{10k} = \frac{49k}{10k} = 4.9.$$

0 volts differential input. With the amplifier connected in a negative feedback configuration, the output will increase until its effects become equal to, and effectively cancel, the input voltage (at the non-inverting input). The principle of the feedback cancelling the input is used to design all feedback amplifiers using high gain op amps — the output stabilizes at a level that reduces the differential input to zero.

If you really want to do more with the signal than duplicate it, you can place some resistors in the feedback loop and give the amplifier any gain desired. The first of two amplifier circuits is shown in Fig. 5. This circuit inverts all signals applied to its input. The gain of this circuit can be computed:

$$A_V = -\frac{R2}{R1}$$

(the — indicates an inversion has taken place). Mathematically, this works out very simply. Since the inverting (−) input is held at 0 V (or some other constant set by the voltage at the non-inverting input), R1 and R2 form a voltage divider whose center

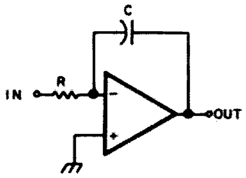

Fig. 7. Op amp integrator (see text).

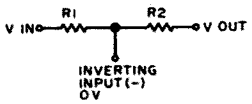
point is at 0 V. Also since the input impedance is supposed to be infinite, the current through R1 is equal to the current through R2:

$$I_{R1} = -I_{R2}$$

or $$\frac{V_{IN}}{R1} = -\frac{V_{OUT}}{R2}$$

or $$\frac{V_{OUT}}{V_{IN}} \text{ (voltage gain)} = -\frac{R2}{R1}$$



Remember that this simple math is only for the perfect amplifier: infinite gain and zero current injected into or sunk from the inputs. R3, I'm sorry to say, is used to compensate for one of the amplifier's imperfections — the current used by the inputs to bias themselves on. Its value (R3) is usually equal to the parallel value of R1 and R2. The idea is that both inputs should see the same impedance to minimize the effect of input bias current. If the input bias current is much less (less than 5%) than the feedback network current, R3 is not really necessary.

The second type of feedback amplifier is the non-inverting type (the voltage follower is a special case of this type; see Fig. 6). Once again, by placing resistors in the feedback loop and input we can tailor the gain to any value. In this circuit R3 has the same function as in the inverting amplifier . . . R1 and R2 are the gain control elements, and by making the same assumptions as for the inverting amplifier, we can see that the currents are equal in both resistors and their common point is held at V_{IN}. The math goes like this:

$$I_{R_2} = I_{R_1}$$

or $$\frac{V_{OUT} - V_{IN}}{R_2} = \frac{V_{IN}}{R_1}$$

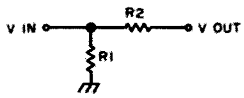
or $R_1 V_{OUT} - R_1 V_{IN} = V_{IN} R_2$

or $R_1 V_{OUT} = V_{IN} R_2 + V_{IN} R_1$

or $R_1 V_{OUT} = V_{IN} (R_1 + R_2)$

Finally, $$\frac{V_{OUT}^{*}}{V_{IN}} = \frac{R_1 + R_2}{R_1}$$

*Voltage Gain.



Input and output impedances of these last two circuits are fairly easy to estimate. The method is nearly the same as for the voltage follower circuit. The only difference is that these impedances are not improved by the full A_{VOL}. Since we "used" some of the gain of the amplifier to increase the amplitude of the input signal, that "used" portion must be deleted from the total A_{VOL}. What's left is referred to as loop gain:

$$\frac{A_{VOL}}{A_{FB}} = A_{LOOP}$$

A_{LOOP} is used just like A_{VOL} was previously:

$$Z_{IN} = (Z_{DIFF})\,(A_{LOOP}) \text{ and } Z_{out} = \frac{R_{out}}{A_{LOOP}}$$

Any impedances in series with the amplifier terminals have to be added to the computed impedance. This usually makes no difference to the input but can change the output considerably.

Non-Linear Feedback

You have seen how placing resistors in the feedback path can affect amplifier characteristics. Now what would be the effect of a capacitor stuck in the feedback path? Let's start with the circuit shown in Fig. 7. This, as you notice, is very similar to the inverting amplifier shown previously, except for the substitution of C for R2. And also the gain formula originates in the same way. This is going to be a little more complicated since putting a capacitor in there tells us there is going to be a time factor. Let's give it a try: The currents through C and R must be equal since their junction is at a high Z fixed voltage point. So: $I_C = -I_R$

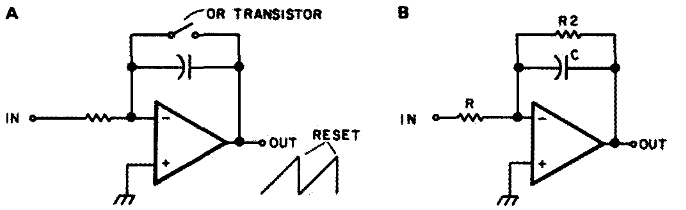


Fig. 8. Integrator modification to correct for offset drift. (a) Ramp generator application. (b) AC application — leaky integrator.

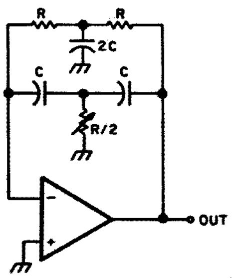

Fig. 9. Twin T sine wave oscillator. $f_{OUT} = \frac{1}{2\pi RC}$. *R/2 adjusted until circuit just oscillates.*

We seem to have run into trouble right away since it's hard to give a resistance value to a capacitor. But luckily:

$$I_C = \frac{C \cdot E}{t} \quad \text{(C in farads, E in volts, t in seconds)}$$

Sticking that in the formula,

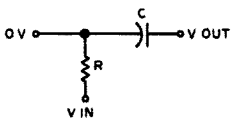
$$\frac{C \cdot V_{OUT}}{t} = -I_R = -\frac{-V_{IN}}{R}$$

Now we're getting somewhere. The gain is then:

$$\frac{V_{OUT}}{-V_{IN}} = \frac{t}{RC}$$

You may be wondering what that's supposed to mean. Not much as it stands, but change a few terms around and:

$$V_{OUT} = \frac{t(-V_{IN})}{RC}$$



With any given components (R and C) and with a given input (V_{IN})(hold them all constant), V_{OUT} will increase linearly with time (a ramp generator!). Increasing the RC product will lower V_{OUT} in a given time or will increase time for a given V_{OUT}. By reversing the polarity or amplitude of V_{IN} the direction and slope of the output can easily be controlled.

This circuit is generally known as an integrator and functions the same as an RC integrator except that the circuit (with the op amp) has the advantage of linear operation, higher Z_{IN}, low output impedance and voltage gain.

If the gain of this circuit is plotted versus frequency, it will be seen that the gain is infinite (or A_{VOL}) at dc and then begins to drop off 6 dB per octave starting at a point determined by R and C. The frequency is actually:

$$\frac{1}{2\pi RC}$$

Looking at it this way, this circuit turns out to be a low pass filter. By placing appropriately frequency sensitive components in the feedback network almost any response can be generated. This is the basis of active filters which have been adequately covered in a previous article[1]. Anyone interested in active filters should read that article.

If you want to try an op amp integrator there is a practical problem that should be mentioned. If the circuit of Fig. 7 is used as is, the output will tend to drift toward maximum in one direction or the other. This is because the circuit will continue to integrate any offset error at the input even with the input grounded. This problem can be eliminated when using the circuit as a ramp generator by resetting the circuit at the end of each ramp with a switch or transistor across the capacitor (Fig. 8a). Closing the switch causes the output to return to whatever input appears at the non-inverting input (in this case zero). The switch is then opened when you want to start integrating again.

When integrating an ac signal, special arrangements must be made since integration must be continuous. One thing you could do is to synchronize the input to the integrator output. When the output reaches some maximum level, the input should change to run the integrator output in the opposite direction. The only use for this method I've seen is for a type of oscillator.

The most practical method of using an op amp integrator with an ac input signal is shown in Fig. 8b. An extra resistor, R2, is added. This resistor provides enough feedback current to cancel any error at the input. Of course, this simple solution does have its problems. The gain and frequency range of integration are reduced by some degree and the operation performed by the circuit is not a true integration. But these effects are relatively minor so this circuit should work well in most situations. The circuit is known, appropriately, as a leaky integrator.

Another area of non-linear feedback circuits is that of oscillators. Oscillators differ from the previously described amplifiers in that they use *positive* feedback. How that feedback is handled determines the type of oscillator and the type of output. Actually, any type of oscillator can be implemented using op amps. The trick is to combine a gain element (the op amp) and some sort of frequency sensitive phase shift element. A few examples follow with not much math.

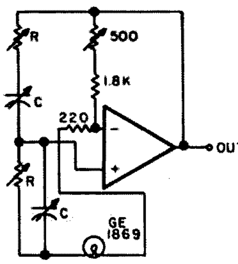


Fig. 10. Wein bridge oscillator.

$$f_{OUT} = \frac{1}{2\pi RC}$$

Sine Oscillators: Sine wave oscillators using operational amplifiers are very similar to discrete oscillators except that the op amp is the active element. The first shown is known as a twin T or double integrator Oscillator. [Note: An integrator provides a 90° phase shift to a signal at the frequency:

$$f = \frac{1}{2\pi RC}$$

The double integrator ought to (and does) provide a 180° phase shift at that frequency. The RC network provides 180° phase shift at the oscillation frequency (see Fig. 9). An interesting feature of this circuit is that if R/2 is adjusted so that the circuit just does *not* oscillate, you have a narrow bandpass filter. Apply the input through a resistor to the (−) input.

Another sine oscillator is the famous Wein Bridge, shown in Fig. 10. The output is a very low distortion sine wave.

Square Wave Oscillators: A simple multivibrator type circuit which generates a

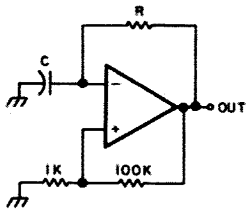

Fig. 11. Square wave oscillator.

$$f_{OUT} = \frac{1}{2\pi RC}$$

square wave is shown in Fig. 11. The output will alternately switch from full positive output to full negative output.

Another oscillator that produces a square wave also generates a linear ramp triangle wave. It consists of one op amp wired as an integrator while the other is wired as a comparator whose reference changes according to the slope of the integrator output. This circuit is commonly used as the basic oscillator in function generators[2]. See Fig. 12.

In this section I've tried to show in a general way how the operational amplifier functions in a circuit. These examples are by no means all that can be done with these amplifiers. Manufacturers' data books and application notes are full of additional information. With a little experimenting and simple design work it shouldn't be too difficult to think of a few applications of your own. Before you start, there is one more thing you should be aware of.

Compensation

While most operational amplifiers used today have no need for compensation (they are already internally compensated), there

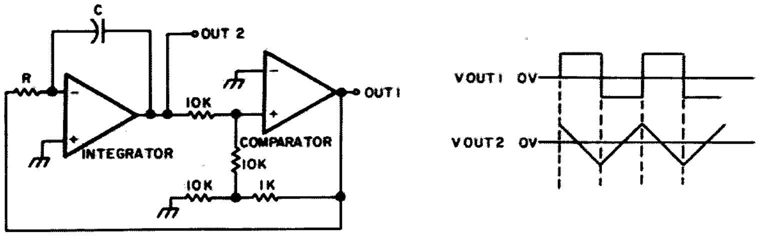

Fig. 12. Simultaneous square and triangle wave generator. $f_{OUT} \approx \frac{0.55}{RC}$

are some applications where it is necessary to use an uncompensated amplifier and do the compensation yourself.

First we must determine what compensation is and why it is necessary. Unlike the perfect amplifier, our op amp has a limited bandwidth. At some high frequency point the response (gain) tends to fall off. Without compensation the rate of fall off is usually quite fast. When the op amp is used as a feedback amplifier, there is a point where the open loop gain equals the closed loop gain. If the open loop gain at this point falls off too fast, the circuit may oscillate at that frequency. The only way to avoid instability or oscillation is to make sure that the rate of open loop gain fall off is 6 dB/octave or less at the crossover point. That is the function of compensation – causing the gain of an amplifier to fall off in a predictable way to prevent instability.

An internally compensated amplifier is adjusted so that the gain starts falling off at 6 dB/octave (20 dB/decade) at about 2 Hz. The voltage gain drops to 0 dB at 1 MHz (for the 741). While this guarantees that the amplifier will be stable under any conditions, it limits the gain severely at high frequencies. To obtain high gain at high frequencies an uncompensated amplifier has to be custom compensated to begin the 6 dB/octave fall off at some higher frequency. The instructions for compensation are usually contained in the manufacturer's specification sheet. For example, a UA709 can be compensated for 60 dB gain up to 500 kHz while the internally compensated UA741 would only be good for a marginal 10 dB voltage gain at that frequency. Internal compensation is only there for convenience; there are some advantages to non-compensated op amps. Some common uncompensated types are UA709, LM301 and LM308. Compensated types include UA741, 5558 and LM307.

Some Other Amplifiers

This entire discussion so far has concerned common op amps of the 709-741 variety. These have bipolar transistor input and are voltage controlled voltage output devices and usually require a balanced power supply. But the IC industry has definitely not stopped there. There are amplifiers with high slew rate outputs (531), Darlington transistor inputs (LM316), FET inputs (536), single supply requirements (LM324 – this device also boasts four amplifiers in one package), and even some that require very low power (533). While some of these have some fairly special characteristics, they operate much the same as the old 709.

There are other type amplifiers that don't operate exactly like an op amp. RCA has a family of devices called transconductance amplifiers. This means they are voltage controlled, *current* output devices. What they've come up with is a high gain, differential input, solid state vacuum tube (or FET). Regretfully, I have no information about them so I can't give any definite applications.

Another interesting device (which I happen to know something about) is the LM3900. These would be called operational amplifiers except that this device amplifies the difference in the *currents* into the inputs. The currents required are fairly small (usually around 10 uA), so large value resistors in series with the inputs can turn this into a voltage amplifier if that is necessary. Positive features of this device (according to National Semiconductor) include its ability to operate with either single or bipolar supplies, a large output voltage swing, a fairly wide bandwidth even with internal compensation and its low cost (there are four amplifiers to a package for less than 60¢).

A few typical applications are shown in Fig. 13. For more information contact National Semiconductor[3]. Their data sheet includes several pages of applications for this device. The spec sheet says these devices are designed primarily to produce ac amplifiers, RC active filters, low frequency waveform generators, tachometers, or low frequency, high voltage logic elements. Try your hand at some of them or adapt some regular op amp circuits. Remember, this device can also be treated as a perfect amplifier except that the inputs are controlled by current, not by voltage as in a normal op amp.

In this article I've tried to give a broad outline of the whys and wherefores of operational amplifiers. While this is nowhere near all there is to say about op amps, it is hoped that those triangular symbols are now less of a mystery. Go through this magazine and see if you can analyze the operation of any op amps used in other articles (my luck, this is an antenna issue or something). For more information Motorola[4] publishes several application notes: AN-204 – "High performance Integrated Operational Amplifiers," AN439 – "MC1539 Op Amp and its Applications," and AN-522 – "The MC1556 Operational Amplifier." If you have access to a technical library, Burr-Brown (a well established op amp manufacturer) publishes a book (*Operational Amplifiers*) that contains all the information you would want. Manufacturers' spec sheets will also contain a great deal of information. The more information you have and use (and hopefully this article was of some help), the less mysterious those "triangle things" can become. ■

Phone Patching '76

--automatic single frequency patch

Phone patches have been popular for many years, and the advent of repeater systems spawned a new age of phone-in-the-car enthusiasts. Many VHF and UHF repeaters have automatic telephone patches, i.e., autopatches. The telephone service is an easily added system feature and renders hours of enjoyment and a potential for substantial public service.

There are those among us who have become so fascinated with the autopatches that they are an end in themselves. That is, the underlying motivation for building a repeater is the promise of mobile telephone service. We all know about not being allowed to use these systems for commercial purposes, but there are many non-commercial applications that are both fun and of significant public service. Applications range from receiving shopping lists from home to reporting traffic mishaps, fallen power lines, etc.

The conventional autopatches, so frequently an integral part of repeaters, are characteristically half-duplex devices. This means you can either talk or listen, but not both at the same time. The common HF phone patches are typical of this mode of communication. For a full-duplex patch you would need to simultaneously receive and transmit. This would require the mobile transmitter and receiver to be operating at the same time. For most amateurs, this would pose significant technical problems, not the least of which would include an additional antenna or some type of diplexer to use a single mobile antenna. The telephone company has already perfected this mode of operation. Of course, the full-duplex approach uses two radio frequencies (one for transmit and one for receive) and provides "realistic" telephone service — you can do all the things characteristic of telephone conversations — butt in, insert lots of "uh-huhs," etc!

For casual amateur purposes, it may not be necessary or practical to worry about full-duplex service. But if half-duplex service is adequate, then why utilize two valuable radio channels? Why not use repeaters to extend the range of reliable communications and single frequency telephone systems to provide half-duplex telephone service? At least this is a nice technical thing to think about even if telephone-only systems might cause the FCC to experience a new set of amateur problems. After all, what is a fully automatic base station that renders telephone service? It's certainly not a repeater for it doesn't repeat. It's not a remote base for it never functions as a base for the mobile user — or does it? Well, anyway, let's continue the technical considerations.

Types of Single Frequency Phone Patch Systems

Several types of single frequency phone patch systems can be considered and then discussed in turn:

1. Manual phone patch
2. Manual-VOX phone patch
3. Automanual phone patch
4. Autovox phone patch
5. Time division phone patch

The following discussion will demonstrate that all of these systems are practical and that the last three are capable of providing fully automatic (autopatch) service on a single radio channel.

Manual Phone Patch

A manual phone patch is typified by the many phone patches operated on the HF bands. The phone patch is manually attached to the telephone line by the base station operator and the transmitting and receiving periods are likewise controlled by the base station operator. Typically, the operator responds to the keyword "OVER" which causes him to reverse the transmit/receive mode. If you've ever run such a patch for people not speaking your native language, you know the confusion that can result if you don't hear "OVER." The manual patch provides half-duplex service and uses only one radio frequency (assuming the two stations are "netted). Fig. 1 shows a typical activity sequence.

Manual-VOX Phone Patch

The manual-VOX phone patch is a relatively simple extension of the manual patch. Again, the base station operator manually

attaches the phone patch to the telephone line. In this system, a VOX circuit detects the telephone party's speech and in turn, keys the transmitter. Again, the keyword "OVER" is sometimes valuable to enhance coordination between the telephone party and the distant radio user. At least in this system, the radio operator is not needed to accomplish the individual transmit/receive actions – a level of automation has been accomplished. This patch provides half-duplex service and uses only one radio frequency. Fig. 2 shows a typical activity sequence.

Automanual Phone Patch

An automanual phone patch does not require a base station operator. The phone patch is attached to the telephone line upon receipt of a command from the radio user. The user simply transmits a special audio tone which is detected at the base station receiver. Once the patch is attached, the radio party transmits additional tones which are used to accomplish the number dialing (previously done by the base station operator). The base station control circuitry causes an identifying tone to be applied to the telephone line so that when the called party answers he can identify the fact that he is receiving a call from a radio user. This causes the called party (assuming he's been so instructed) to request use of the transmitter by sending a control tone – e.g., Touchtone "1". He likewise marks the end of his transmit period with a control character – e.g., Touchtone "2". When the telephone call has been completed, the patch is disconnected from the telephone line in one of two ways:

1. A circuit detecting the fact that the called party has placed his handset "on-hook" generates a disconnect signal; or
2. A control tone is sent by the radio user.

This system is semiautomatic – the phone patch is attached and released without a base station operator intervening. However, the switching between transmit

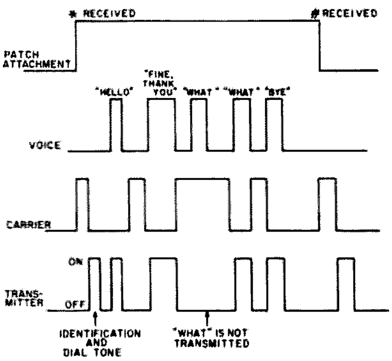

Fig. 4. Base station equipped with autovox patch. Note how first "What?" isn't transmitted – VOX is inhibited when a carrier is present.

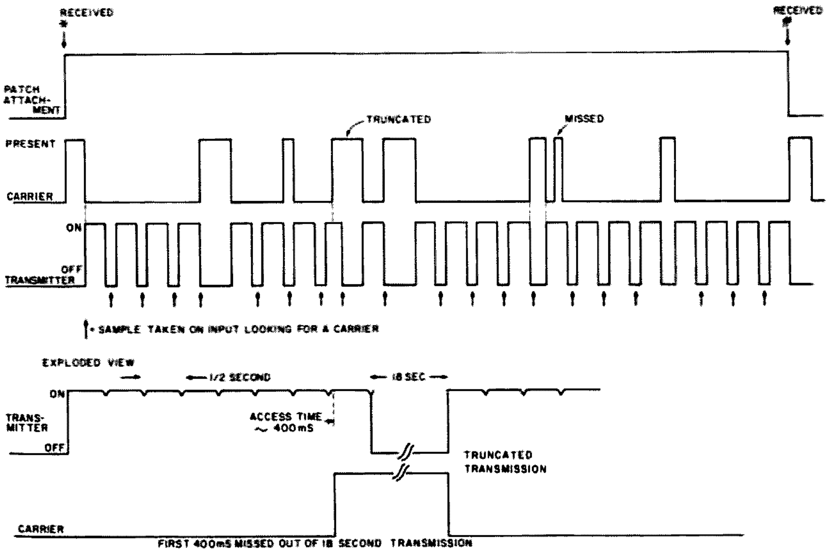

Fig. 5. Time division patch.

and receive is controlled by the telephone party – a less than ideal situation since many people called may not be trained or equipped to perform this function. If you intended to always call telephones manned by appropriately trained people and equipped for this type of operation, then this simple system would render a pseudo-autopatch service in a reasonable way. It is automatic, half-duplex, and uses a single frequency. Fig. 3 shows a typical activity sequence.

This system poses very interesting legal questions. The typically unlicensed telephone party controls the transmitter via special actions – namely transmitting control tones. Think for a moment about a telephone handset equipped with a PTT button (such things exist). Now consider a "beeper" circuit that generates one audio signal when the button is depressed and another when the button is released. The called party now looks very similar to a normal radio operator. Who's really in control of the transmitter? At least *at times* it's probably the telephone party with the transceiver functioning as his remote base station! Other systems exhibit this same problem – the time division patch (to be described later) solves this problem.

Autovox Phone Patch

An autovox phone patch is the logical extension to the automanual phone patch. Again, control tones from the radio user are used to attach and release the phone patch. However, the periods of transmit and receive are basically controlled by the telephone party's speech. This system allows the radio party to render all of the significant control functions while enabling the called party to initiate the transmit and receive periods without needing special equipment or instructions. This patch is fully automatic and renders half-duplex telephone service on a single frequency. Fig. 4 shows a typical activity sequence.

Time Division Phone Patch

The time division phone patch derives its name from the fact that the base station control logic divides the transmit time into periods of transmission *and* reception. During very brief receive periods that take place during interruptions to the normal transmit activity, the system receiver is able to detect the user's incident carrier and therefore cease transmitting and enter a prolonged receive period. This patch introduces additional technical complexities to the base station (no changes to mobile users), but renders better service in that the radio

user is in full control of the system (unlike *any* of the other systems wherein the user is at the mercy of the base station operator, a telephone user, or a VOX circuit). The time division phone patch is fully automatic, renders half-duplex telephone service, and uses a single frequency while enabling total radio party control. Fig. 5 shows a typical activity sequence.

Practical Considerations

Each of these systems has its strong and weak points – some require a base station operator, some do not, some require sophisticated control logic and some do not. You can't have your cake and eat it too! However, all of these systems will work. Most of us are quite familiar with the first two systems having either built patches, used patches, or been served by patches. The others are less well known. The automanual patch, while relatively simple, has extremely limited usefulness, and so it's not very interesting for general application. The autovox patch and time division patch are quite workable and worthy of further study.

State Diagrams

State diagrams are a popular graphic convention used in the fields of electrical engineering and computer language processing. State diagrams are a helpful aid to understanding complex event sequences. Following a brief description of state diagrams, each of the patch systems will be described and discussed using this graphic convention. It is then possible to build appropriate control circuits to in effect "implement" the state diagrams.

The idea of a "state" needs to be understood before continuing. A state is representative of a particular *condition.* For example, a 2 digit binary counter has four states – 00, 01, 10, 11. The counter can be in any one of these "states"; i.e., the counter's "condition" is that it contains 00, 01, 10 or 11 as the count. A state diagram consists of a series of circles containing numbers indicative of a particular state. The circles are connected by lines showing what stimulus causes a *transition* from one state to another state. Fig. 6 shows a simple state diagram that describes the operation of a typical mobile transceiver.

The system has three states – named state 0, state 1 and state 2. State 0 is characterized by no activity, state 1 is the receive state, and state 2 is the transmit state. Note that the state diagram shows what happens to the system as a function of various actions. Note that the amount of detail shown is a function of the clarity you wish to show. Fig. 7 shows a further enhancement of the transceiver state diagram. Note how this completely describes the system – there are *four* states – 0 through 3. There are two primary controls: the power switch and the PTT button. Both of these switches have two positions – ON and OFF. A truth table shows these combinations:

STATE	PTT	POWER	
0	0	0	0 means switch "off"
1	0	1	1 means switch "on"
2	1	1	
3	1	0	

Specific State Diagrams and System Descriptions

Figs. 8(a), 8(b) and 8(c) show state diagrams for the first three phone patch systems discussed. Figs. 9(a) through 9(c) show state diagrams for an autovox patch.

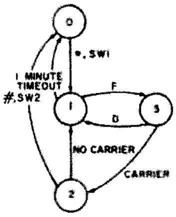

Fig. 10(c). A practical time division patch system.

patch system. A user transmits a "*" to activate the system. The system immediately responds by attaching the patch and keying the transmitter to broadcast the dial tone. A normal VOX circuit would continue to key the transmitter due to the presence of the dial tone. The control logic includes a five second timeout to keep this from happening. State 2 is a receive only state and during this period the user transmits number dialing information — either via a rotary dial or Touchtone pad. The user marks the end of the dialing activity by sending a *. State 3 is a general receive state. If the user transmits a signal, the control logic goes to state 5 where voice on the phone line is ignored (the radio user has control). If voice is detected during state 3, then state 4 is entered and the transmitter is keyed to broadcast the telephone party's voice. When there is no more voice present, state 3 is reentered. The patch is disconnected when a # is received in state 5 — user is in control and transmits a #. Note that the user cannot get control when the system is in state 4. The base station transceiver is not receiving! Several improvements can be made to this system.

Fig. 9(b) describes a better autovox patch system. In this system, three additional states have been added to allow the mobile an opportunity to gain periodic control.

If voice persists for 10 seconds (system stays in state 4 for 10 seconds), then state 5 is entered. State 5 causes the transmitter to be turned on and an "alerting audio tone" is applied to the transmitter's input. After 500 ms of this tone, state 6 is entered for a maximum of 1 second. If the mobile user keys his transmitter, the resulting carrier will cause state 7 to be entered wherein the user can talk to the telephone party and/or transmit a control character such as # to disconnect the patch. This type of control logic enables the system to accommodate situations such as an over-sensitive VOX circuit, a long-winded telephone party, or a call to a telephone located in a very noisy area. The voice and carrier signals are mutually exclusive in that the presence of a radio signal causes the voice signal to be ignored and a voice signal causes a radio signal to be ignored — in fact "missed" since the transmitter is then on and the receiver is then off.

Additional improvements can be made through the addition of timers and escape paths. Fig. 9(c) shows the state diagram of a good, workable autovox patch system. (This logic has been fully implemented using T^2L logic to control a 2 meter autovox system.) Several significant features have been added to the system shown in Fig. 9(b). A minor improvement consists of introducing a state to keep the autopatch system from QRMing the user at start-up time (state 2 is not entered until the carrier that presented the * has ceased). States are also included to "block" toll calls. When the dialing state is entered (state 3), an initial 0 or 1 will abort the control sequence. Note also that the system only provides 10 seconds for the first valid digit. The user may also deliberately abort the control sequence by sending a #. It is thus possible to "test" the system by transmitting a * and then a #. Receipt of a valid first digit (2, 3, 4, 5, 6, 7, 8 or 9) causes state 4 to be entered. In this state the additional digits composing the telephone number are "dialed." If an error is made, a # may be used to exit the control sequence. If the user is too slow, or if his signal fades out, a 10 second timer aborts the control sequence. The end of dialing information is indicated by the user transmitting a * which moves control to state 5. States 5, 6, 7, 8 and 9 function the same as states 3, 4, 5, 6 and 7 in Fig. 9(b). State 10 is added to serve as a terminal state which initiates an identification sequence. In fact, in the actual implementation, an identification sequence was initiated upon entry into state 3, at periodic intervals during use, and upon entry into state 10. State 11 can be entered by sending a "D" to "kill" the system — theoretically "pulling the plug." The 1 minute timer associated with state 5 causes the system to abort if there is no activity for a period of 1 minute — no activity being no signal received and no voice on the telephone line. In addition, a call length timer is associated with the system being in any state other than state 0; to allow for longer telephone calls, the user can reset this timer by sending a "D" character.

There are two significant weaknesses in the autovox patch system. First, the radio user can only grab control in particular states — 5 and 8 in Fig. 9(c). This limits the user's ability to inhibit a runaway system or censor an over-excited telephone user. The second weakness is in the use of a VOX circuit. Reliable VOX circuits are a rarity unless they become rather sophisticated electronically. On the other hand, the system is fully automatic, uses only a single frequency, and provides reliable service when properly adjusted.

Fig. 10(a) describes a simple time division patch system. While the state diagram is simple, the system is quite impressive in terms of its operational characteristics. Upon receipt of the access control

character, a *, the system attaches the patch. The transmitter is keyed whenever the system is in state 1. For the sake of simplifying the discussion, assume for the moment that a carrier is not received. In this situation, state 3 is entered after the system has been in state 1 for 990 ms. State 3 is left after 10 ms. The system thus cycles between states 1 and 3 – staying in state 1 most of the time – in fact 99% of the time. (Note: Time is divided between transmitting and receiving – thus the term time division.) In state 1, the patch is attached and the transmitter is keyed; in state 3 the receiver is on and the transmitter is off. Consequently 99% of the telephone party's audio signal will be transmitted. Now, consider the effect of an incident carrier. If a signal is detected during the 10 ms time period that the receiver is active (via state 3), then state 2 is entered and the receiver remains activated (and the transmitter disabled) until the incident signal ceases, thereby causing state 1 to be entered. Since the receive state is entered approximately once every second, the *average* time needed for the system to detect a mobile user's signal is ½ second. From the user's point of view, this means that when he starts to transmit, his voice will be heard on the phone line within a maximum of 1 second – ½ second on the average. Actually, his signal will be detected within 0 to 990 ms; sometimes it will be detected immediately, other times not nearly so quickly.

The radio user will not receive all of the telephone audio – only 99% of it. Careful studies have been made to determine the effect of "missing audio" on the listener's ability to understand the information being transmitted. There are three principle factors:

1. How often the signal is interrupted;
2. How long the interruption lasts;
3. What replaces the missing signal.

Fig. 10(b) summarizes the author's subjective evaluation of an experiment performed by Chuck Fenwick WØFTM. The interruption rate and interrupt duration were varied while the same speaker read the same text at the same rate. The missing sections were replaced with silence.

In an operational time division autopatch system, the missing information would probably not be replaced with a zero signal. If VHF-FM is used, the lack of a signal produces a hissing sound; if AM is used, the lack of a signal is generally quiet, but certainly not totally quiet; other modes would have other characteristics.

Several practical considerations must be made in a time division patch system. The frequency of entering the receive state and the duration within the receive state must be carefully chosen. Ideally, you want to enter the receive state frequently and stay as short a time as possible. Entering frequently enables the user to gain access quickly; staying a short time minimizes the loss of information transmitted from the phone line

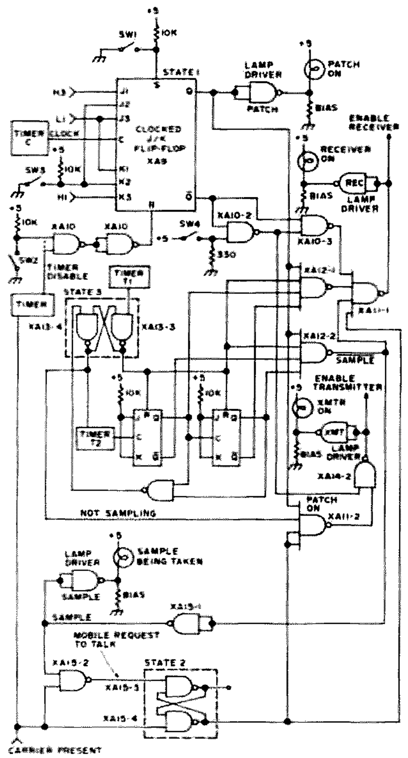

Fig. 11. Control logic.

due to the deactivated transmitter. A practical limit results from the inability to stop transmitting instantly and start receiving instantly. Even if this were possible, the speed of the carrier detection circuit must be considered. The operation is smooth when the frequency of interruption is a second or less and the duration is limited to a few milliseconds.

Fig. 10(c) describes a practical time division patch system which I have built and operated. The patch is activated by the * character or a depression of switch SW1. The system is deactivated by the #, or a 1 minute timeout (no carrier for 1 minute), or a depression of switch SW2.

An Operational Autovox System on 2 Meter FM

The autovox system described in Fig. 9(c) was implemented on a series of circuit cards using surplus T^2L logic components. One significant comment can be made about the implementation: It could have been better! The initial temptation is to view each state on the state diagram as a memory element – i.e., a flip flop. This approach results in 12 flip flops – one for each of the states 0-11. However, each flip flop has two states – either set or reset. If there are twelve flip flops, each of which can have two states, the system can theoretically assume any one of 2^{12} states! (Two flip flops can assume four states – 00, 01, 10 and 11, three flip flops can assume eight states, and twelve flip flops can assume 4096 states!) But, out of these, only twelve states are valid. A better implementation can be made by using a four-bit counter which can assume 16 states – 0 through 15. The logic that one builds then in effect says, "If the counter's value is V and action A occurs, then set the counter to M." Simple logic can detect the illegal states (entered perhaps via a noise pulse) and cause the counter to be set to some specific value. The counter's value is then indicative of the system's state. The counter is set to a particular value (system state) in response to detecting particular conditions in conjunction with a specific counter value. Fig. 12 shows in a general block diagram manner how logic for Fig. 9(a) would be implemented. Figs. 13(a) and 13(b) illustrate two approaches to implementing the set logic and state counter (actually a register). Fig. 13(b) is preferred since it isolates the setting logic from the state register itself. The practical implementation did not follow these guidelines but was a piecemeal project built up as a series of small logic modules. The actual logic details are not all that important, providing that the state diagram is faithfully implemented in the hardware.

A system diagram is shown in Fig. 14 to illustrate the component parts of the system – above and beyond the control logic.

While the heart of the system is the control logic, the most sensitive component is the VOX unit. The VOX unit employed was an adaptation of the solid state unit appearing in the 1972 edition of the ARRL Handbook. Minor modifications were made in the anti-VOX circuit to adapt its operation to this application.

The most difficult problem that had to be overcome was false tripping of the VOX circuit each time the transceiver (a Motorola W43GGV) switched from transmit to receive. The problem caused cycling – the unit would switch from transmit to receive to transmit to receive, etc. The problem was traced to the fact that dc microphone bias was being switched on and off. Removing

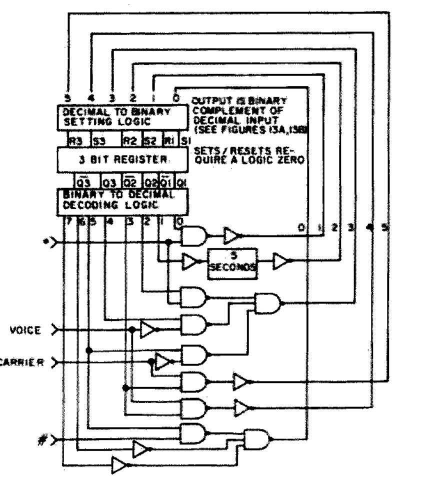

Fig. 12. Block diagram of recommended autovox system logic.

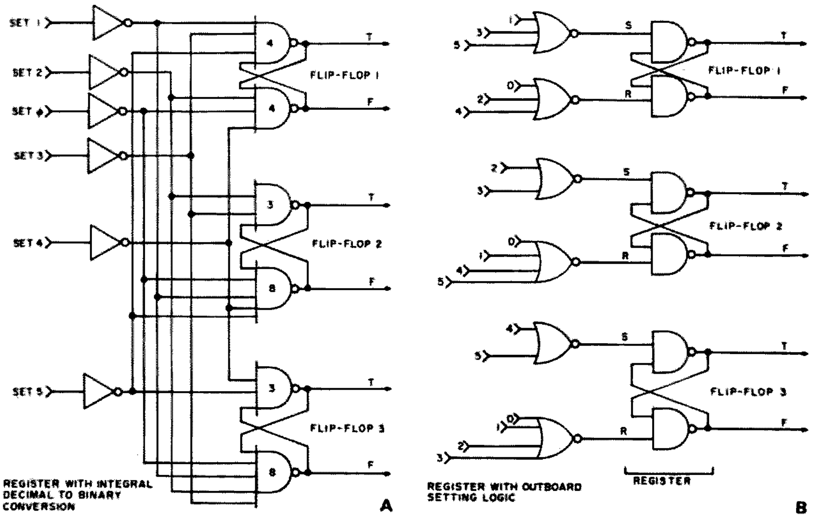

Figs. 13(a) and 13(b) illustrate two ways to implement the set logic and state counter.

the bias circuit, intended for carbon microphones, cured the problem.

The VOX circuit should have fast attack and slow release to be most effective. Employing some agc ahead of the VOX unit can be helpful in accommodating various speaking levels and telephone circuit conditions. The most serious operational characteristic occurs when the telephone party responds to questions too quickly, resulting in a missed or partial transmission – the result of the VOX attack time and transmitter keying time. The same problem occurs on conventional two frequency autopatch systems as well when the telephone party responds before the mobile user has had time to switch from transmit to receive.

The autovox patch is easy to use and can render service if a good VOX circuit is employed. The system's primary weaknesses include the variability inherent to VOX circuits and the fact that the mobile user doesn't have absolute control of the system (he must wait to grab control).

An Operational Time Division Autopatch on 27 MHz AM

To help in the investigation of a time division autopatch, the control logic shown in Fig. 11 was constructed using T^2L components derived from discarded computer circuit boards. Flip flop XA9 is the mode control flip flop and is representative of state 1. This flip flop is set either by a push-button switch, SW1, or upon receipt of the * character (tone detector outputs H_3 and L_1); it is reset by a push-button switch, SW2, upon expiration (momentary logic 0) of the 1 minute timer, or upon receipt of the # character (tone detector outputs H_1 and L_1).

The sampling process, i.e., looking for an incident signal, is accomplished by use of a 2-bit binary counter. The sampling process is actually sub-divided into four periods. Fig. 15 shows the actual sampling process. A unijunction timer is used to determine how frequently this process is performed – in the experimental system, several time periods were switch selectable between approximately two times per second and once every five seconds (the basic timer circuit is shown in Fig. 16). The rate at which the 2-bit counter was cycled was controlled by a separate UJT clock circuit controlled by a variable resistor to provide widely variable sample durations. Fig. 11 shows the frequency control timer as T_1 and the sample clock as T_2. The flip flop composed of gates XA13-3 and XA13-4 is representative of state 3. The flip flop composed of gates XA15-3 and XA15-4 is representative of state 2. Gates XA12-1 and XA12-2 decode the counter to determine when the receiver should be enabled. Gate XA12-2 decodes the second "receiver-on" period and thus generates the "SAMPLE" signal as well.

Gate XA11-1 produces an enable for the receiver under four conditions:

1. Sample period 1 or 2;
2. Carrier present on input;
3. Patch off;
4. Local mode and PTT button not pressed (gates XA10-2 and XA10-3).

Gate XA15-2 causes the flip flop composed of gates XA15-3 and XA15-4 to be set when a carrier is detected during the sample period. Gates XA11-2 and XA14-2 compose the transmitter keying logic – providing an enable under two conditions:

1. Local mode and PTT button pressed;
2. No sampling in progress and no incident carrier.

This logic was interfaced with modified Radio Shack Model TRC-4 100 mW CB transceivers that were interconnected with a simple phone patch. Reliable operation was obtained while wandering around the house carrying an unmodified TRC-4. For simplicity, one transceiver was used as the receiver and the other one, with PTT button wedged "on", was used as the transmitter.

Lots of experimental work was done to get reasonable response times. The transmitter was not modified – simply keyed on and off with a transistor switch in the power lead. The receiver required modification in the agc circuit to speed it up. Because of capacitor charge conditions, the receiver came on most *insensitive* and gradually increased its sensitivity. A transistor switch was added to remove the capacitor until a signal was detected and then replace it to control the amplification process and reduce distortion. A carrier detector was added to produce a dc voltage when a signal was detected. This signal was in turn amplified by op amps, passed through a Schmitt trigger, then to a monostable, for delayed dropout. The output of the monostable was the signal named CARRIER appearing in Fig. 11. This simple account over-simplifies the matter somewhat because receiver sensitivity was still somewhat deficient. This may have resulted from transmitter turn-off problems. Having no equipment other than a VOM, it was difficult to really study what was happening. Adequate equipment and a better electronic engineer could have no doubt worked wonders! But, the circuit did work – so well, in fact that on several occasions, I talked with my father over long distance circuits and he was totally unaware of the radio system's operation.

The radio party hears a "tick" each time the base station ceases transmission to look for a carrier; the telephone party hears only the received audio since audio gating is enabled only when a signal is present.

Just for the sake of proving it could be done, the control unit was connected to a stock Motorola W43GGV tube-type transceiver. By making the sample period very long, even a unit with PTT *relays* worked acceptably. While this is certainly not recommended, it would be interesting to attach a fully solid state unit employing solid state antenna and power switching (such as the Varitronics IC-2F). A suitably designed transceiver could no doubt vastly improve overall system performance by rapidly getting the transmitter squelched and the

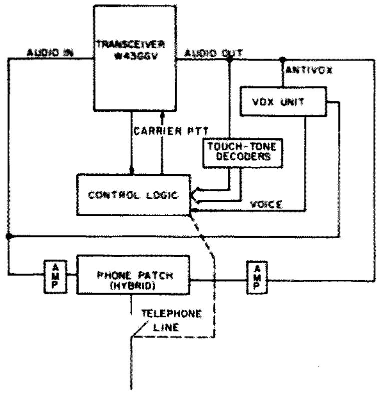

Fig. 14. Component parts of a practical autovox system.

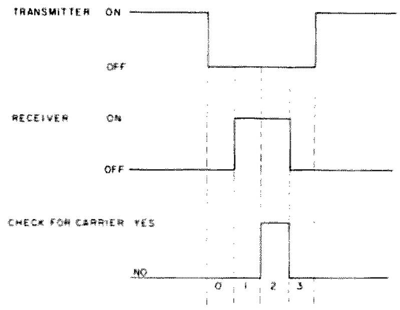

SAMPLE PERIOD COUNTER VALUE	ACTION
0	Transmitter off
1	Receiver on
2	Check for carrier
3	Receiver off

Fig. 15. Detailed carrier sampling process.

receiver up to maximum sensitivity.

The time division autopatch has many significant positive characteristics:

1. It is fully automatic;
2. Control is in the hands of the radio party;
3. It uses a single frequency;
4. It uses a single antenna with no need for a diplexer;
5. It requires no special phone line quality or telephone party conduct.

It also exhibits one significant negative characteristic – the base station must be

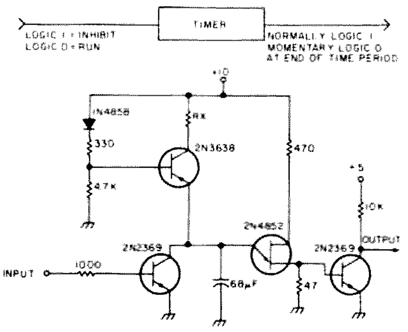

Fig. 16. Basic timer circuit.

able to switch from transmit to receive very quickly.

Conclusions

All of this thinking and work with single frequency autopatches came about because one Florida amateur, after reviewing my repeater system equipped with an autopatch, said to me, "It's too bad you can't build a single frequency autopatch." To Hank Bach, I say "Thank You." The thinking and researching have been rewarding. Maybe one of these autopatches, perhaps the time division autopatch, will be just what is needed to provide reliable half-duplex telephone service on a single frequency to thousands of mobiles already equipped with various types of standard transceivers.

Legality Considerations

The FCC's revised repeater rules are known to us all. This experimental system was designed to be fully automatic and reliable so that the need for a base station operator could be totally eliminated, while at the same time it halved the amount of frequency spectrum used (compared to conventional autopatch systems). The FCC has taken a dim view of "telephone only" repeaters, yet many repeaters exist mainly to support everyday telephone communications. So far as I know, a system such as the automatic VOX patch might be legal for the land mobile service although not for the amateur service. My interest has been in advancing the technology – not quibbling over rules and regulations. My goal has been met – it would, however, be enjoyable and encouraging to learn that the operation of such a telephone system for strictly non-commercial purposes and emergency communications was in fact permissible. There are many times each week that I would like to make a personal phone call to check on the family "milk" needs, and at the same time prove that the system is ready to render valuable community service in the event of an emergency. We can only hope that the FCC will recognize the merits of systems such as this one. Can you imagine the potential impact of a national single frequency autopatch system? In the meantime, 10-4 y'all! ■

EDITORIAL BY WAYNE GREEN

from page 24

Considering how things are going, it would seem prudent for all of us not yet active on CB to start looking around for a rig. We'll not only get the smokey clues which CBers are enjoying, but also get to meet some nice people who are solid gold prospects for ham licenses. You'll also find a lot more traffic information available to you while driving than you get through the local repeater . . . CBers outnumber the hams about 100 to 1 these days.

Remember back, you older timers, to when CB was first introduced. At that time a lot of us thought that this would be a great start for getting people interested in ham radio. The illegal type of operation, which the old rules promoted, made the 11m band a playground for the type of people we didn't need . . . and which would never be much interested in amateur radio where they would have to actually work to get a license. The present CB gang has engulfed the old high power bad language creeps and are, for the most part, quite decent people. Now, as the FCC manages to get licenses into CB hands, you even hear actual call letters beginning to replace handles!

We don't have to try to lick 'em . . . just join 'em and sneakily winnow out the best of the CBers and get them into our ham classes. It will be a painless . . . fun . . . missionary job.

Yes, I know . . . I can hear the old curmudgeons now . . . *73 Magazine* . . . the amateur radio and CB magazine. Go soak your heads . . . right after listening to CB 1976 and finding out what it is really like. My apologies if you find CB to be rotten . . . it isn't most places, but there are exceptions.

NEW 220 MHz CB BAND?

Despite the ads by NRI in *QST* and *HR* for their new 220 MHz CB synthesized rig, the FCC assures me that plans for this ham band to go CB are dead. Several readers wrote me about this obviously deceptive advertising, wondering how these magazines could run such an ad. Beats me!

While most of my past prejudices against CB have been overcome by recent developments, I'm not yet ready to cope with CBers on 220 MHz who are convinced that their NRI 500 channel digitally synthesized rig is perfectly legal.

We, as amateurs, do have to come to grips with CB as it is today. We need to understand what it is and how we can best relate with this. Letters are pouring in from all over the country telling me that ham clubs are having more and more success in converting the more intelligent and decent CBers into licensed hams. Bravo.

We also need to be wary. The renegade element which has moved above the 23 channels gets a wild hair every now and then and ventures above 28 MHz. This sort of trip should be stopped with every tool at your disposal. It will be a lot easier to stop now than when the sunspots start perking again and all sorts of rare DX become available.

One of the last things we need is an open invitation for CBers to jump unlicensed into a ham band. Hopefully *QST* and *HR* will correct the idea that there now is a 220 MHz CB band . . . and perhaps take a firmer stand with advertisers who try to run deceptive ads.

My thanks to the many readers who dropped notes to the offending magazines . . . WB2LEI, K7DBU, etc.

BOOK MAGIC

Have you ever started to get into some new phase of amateur radio, only to find that getting the information you want is a bear? You look through your back issues and find some info, but key articles are missing, and you end up spending enormous amounts of time trying to get what you need . . . and kicking yourself for not being more careful of those back issues.

One obvious solution to this misery is to go out and buy a book or two on said new interest so you'll have everything in one place. This is okay if you are into RTTY or SSTV, but a lot of other phases of amateur radio are not covered adequately by books . . . as yet. We're working on this problem at *73*, but we need help.

Publishing specialized books for amateur radio is not one of the all time lucrative efforts . . . which explains why there are not all that many books available. Yet, for the amateur who can write . . . and has a field of expertise . . . there is interesting spare time money to be made. If you are into any amateur specialty . . . say certificate hunting, for example . . . you could work this into one or two thousand extra dollars by contacting me and proposing a book on the subject.

The book series we are working on will all be around 100 pages of 8½" x 11" and sell for $1.95 through the stores. A good book will sell at least 10,000 copies, with some going up to over 50,000 . . . though that is unusual. While most publishers pay royalties on the order of 5%, we will be paying 15% . . . since we don't want to disturb our long-standing nonprofit way of life . . . ARRL is not the only outfit that can lose money year after year and grow nicely in the process. That means there would be a royalty of about 19.5¢ on each copy (wholesale price would be $1.30) . . . *or about $1950 on 10,000 copies.* It isn't a lot these days, but a little bit here and a little there . . . right?

If you can't think of any books to write, it is because you have been riding on the coattails of others. Books would be welcome on things like 160 meters, 75 DXing, contests, traffic nets, low noise circuit design, circuits of commercial amateur rigs (royalties on non-expert material have to be negotiated), buyer's guide to ham gear available, buyer's guide to microcomputer equipment and peripherals, updated index to surplus conversion articles, microwave equipment, getting on 450 MHz, ATV, FAX, intro to microcomputers, intro to common programming languages, mobile handbook, introduction to amateur radio, license manual, how to become a radio amateur, understanding amateur radio, radio fundamentals, amateur operating manual, learning the code, VHF manual, CB equipment guide, getting the most out of CB, things like that.

If you like the idea of some extra money and think you can turn out a good and interesting book, make an outline and send it in for an okay. Proven authors will get preference, of course . . . but this is an opportunity to get your feet wet . . . if you can hack it.

CASH BONANZA

Every now and then I get a letter from some reader sniveling about not being able to afford this or that piece of ham gear. The sniveling is getting even worse with the cost of computer systems running around $2000. My answer is simple . . . you have plenty of good training to make a lot of money in your spare time, so why sit around writing complaining letters to me when you could be out there raking it in?

The CB explosion is a case in point. It is getting tougher and tougher to make a buck selling CB equipment . . . you're in competition with discount stores and truck stops . . . outfits with relatively low overhead and enormous buying power. But remember that these days the big money is in service, not in selling . . . and service is one thing that CBers need . . . desperately.

You could set yourself up installing and servicing CB rigs and do very well in many areas. It is a business you could get started in your evenings and weekends. You'll be able to work in a good deal of accessory sales as part of your business, too . . . for most CBers will be willing to pay quite a bit to get rid of all that car noise . . . and you should be able to sell car security systems like crazy.

How do you get customers? Over the CB channels . . . with business cards at all sales outlets (offer a little kickback to the salesman if you get the installation job . . . make that a "commission") . . . ads in the newspaper . . . etc.

Speaking of car noise, I'm still hoping that somewhere out there at least one *73* reader has discovered how to quiet the deafening noise in a Datsun! Please give me a hint. My 280Z has to be heard to be believed and the local dealer says nothing can be done.

EDITOR NEEDED

73 has an urgent need for a ham in the editorial department. A background in both the technical and operating ends of the hobby will be advantageous . . . as will the ability to read and write. Fun job . . . fantastic area for living . . . reasonable pay . . . lots of hamming . . . excellent opportunity.

BYTE TROPHY

The Southern California Computer Society awarded a beautiful trophy cup to *Byte Magazine*. Here is Wayne Green, the originator of the idea for the magazine and the publisher who got *Byte* started, admiring the trophy.

be my guest

visiting views from around the world

from page 9

of the mode or special interest directly involved. I suspect that it is reasonable to say that those involved in a given mode are the closest we will have to experts in that mode, and therefore they should be the people to work out solutions, unless a specific problem arises between adjacent users of two or more different modes. Even then, it should only be those involved who work toward a solution. However, all findings on any problem should be disseminated to all representatives of all groups, so that meaningful dialogue between various special interest groups can be developed.

Another important input at this level would be that of our international neighboring nations: Mexico to the south and Canada to the north. Let's face the fact that transmitted rf energy rarely if ever observes international, or even state, boundaries. Since rf originating in our country affects them, and vice versa, we must develop the same lines of interaction and intercommunication with them in order to protect their rights and, in the end, thereby protect our own. Then too, we may very well gain from their technology — and that never hurts anyone. Most of all, we gain a good deal of international fellowship and good will by extending the hand of friendship to our neighbors, and this fellowship can only benefit us at the '79 WARC in Geneva. The friends we make now will be of definite benefit then, and in times to come thereafter

By this time I hope you have noted that the arrows connecting the different tiers and organizations in the diagram are all two way. I feel that this is extremely important in that all communication and interaction must be two way; all must work for each other and information disseminated at any level must be made available to all interested. The same holds true for all areas of the country, in that east can learn from west, north from south, neighbor nation from neighbor nation, etc. We must pool what we have already learned and what we will learn in the future so as to avoid repeating costly mistakes — the kind that make enemies out of amateurs who in reality should all be friends working arm in arm toward one specific goal: the future survival and growth of the amateur radio community worldwide. On each level we must break down the walls that now divide us, such as things like "license class bigotry," wherein amateurs of one license class profess superiority over others simply because they have passed a harder test. Or the walls of isolationism between amateurs due to the specialization of the mode in which they operate. I have always believed that it's not the license class you hold or what you are a specialist in that counts, but rather what you as an individual do with these assets and how you use them to benefit the entire amateur community. Though some may not like the realization, the times have changed swiftly for us and are everchanging. Unless he or she wakes up soon, the isolationist and the bigot will very soon be left out in the cold with no home and, even worse, no one to QSO with. It is for this reason that every special interest group must be represented, from the local council and/or workshop level to the statewide level. Now, where to from here?

Logically, one would think that from here we should go national and, while I agree, there are too many pitfalls. While on a local level it is fairly easy to hold meetings, as you progress up the scale distances between given points becomes a significant factor in both time and cost. On a statewide level things would still be quite tolerable, in that such statewide meetings could be held in conjunction with a major amateur radio convention. While admittedly it's an assumption on my part, I really feel that the kind of person who is politically motivated enough to garner election from his particular local council is the same amateur who rarely if ever misses a major amateur get-together such as a Division Convention or other major area happening. Therefore, scheduling meetings of a statewide organization to coincide with a major event such as a Division Convention would probably attract the necessary attendance.

When you speak of a national get-together perhaps twice yearly or even quarterly, you speak of big travel and time expense. This was brought home graphically to me just yesterday, when I learned that a trip Sharon and I are planning to New York later this spring will cost almost $700 for two round trip (coach) airline tickets. No one amateur or group of amateurs could be expected to cough up perhaps two grand per head per year travel expenses. Even if a group did, could you see trying to accomplish anything of value with 100 delegates, plus who knows how many advisors to each (figuring two delegates per state plus one alternate), crammed into one room in Newington? Why Newington? Well, aside from the ARRL, I know of no other organization capable of undertaking as large a job as this.

Therefore, some semblance of order must be achieved before chaos is permitted to develop. Here enters the areawide or regionwide council. Let's say that four such councils were established along time zone or other boundary lines, and that quarterly or semiannual meetings for these councils were established. Now you have quartered the numbers of people attending and minimized as much as possible the travel necessary — and thereby the associated costs. To areas such as Hawaii, Alaska and Puerto Rico, this would be a definite expense benefit.

This level would have two prime purposes aside from the aforementioned. First, it would act to develop lines of communication between its three peer organizations — to collect and disseminate information, and to solve problems between statewide organizations. It would not involve itself in local procedures and policies, as these would be left to the local and state bodies. In fact, its main purpose other than those already stated would be to act as a clearinghouse for information that would be presented from a given area to the heart of the entire body: the National VHF/UHF Spectrum Advisory Committee.

Let us now elect two delegates and one alternate from each Regional Area Council (and fund them with money prorated from dues collected at the lower levels), place them aboard their favorite mode of transportation, and send them off twice a year to the city of Newington, Connecticut. Their job would be the hardest: to analyze all aspects of VHF/UHF amateur operation on an ongoing basis and recommend changes that would benefit all spectrum users. To do this, they would need all forms of inputs and, as the chart notes, as many as possible are provided. First, the people whom they directly and indirectly represent will have given them basic direction as to what is needed. Second, the needs of neighboring nations must also be

More from the Son of a Gun

One of our more strung-out QRPers came up the hill last week, his voice ringing across the ridges, joy in his smile and happiness everywhere. A couple of us were just sitting around and we braced for the worst. "I did it," the QRPer was yelling, "I did it, I did it! This time I got one for sure and it has to be a real blockbuster for sure." We calmed him down to get the story out of him. "This morning, on the dawn path, I worked this AC8BT/AJ4. There was this big pileup of JAs fighting to work the station and I knew that it must be a real rare one. So I jumped in and worked him . . . got a five-eight-nine out of him, too. I don't know where it might be but with Sikkim gone I'm wondering if it might be one of those other Himalayan kingdoms, something around Tibet. It might even be China. What do you think?" Son of a gun, what could one say to something like this on a warm day, the sky blue and the flowering trees all in early bloom? We finally said, "We'll have to research this one and try to get a line on things," and the QRPer was off, jogging his way down the hill. The two of us sat in silence for a bit and finally the other spoke. "Why didn't you tell him that AC8BT/AJ4 is Al Hix from Charleston down in Puerto Rico to warm up a bit?" We were long in answering for there are enough of the dark days and this for now was a happy one for the QRPer. And at the end all we could say was, "Take from no man his dream." And there are yet those happy days in DXing and there will be more to come.

* * * * *

One of our more recent QRPers came by last week and he had a question. "Why are the older DXers always sitting around and talking about the good old days?" he asked. "Were things really all that good and were they really the Big Guns that they say they were?" We have often been troubled by this question ourselves, so we hauled the QRPer over to the Old Timer who listened to the question. "A man must preserve his self-esteem," the Old Timer said, "and some may tend to rewrite the remembrance of other days and other years. The years that are gone will always be the golden years. It comes to most everyone." Son of a Gun, you would have thought that the QRPer had all the answers he needed, but he persisted. "But did all those things really happen? Are all the things they say true?" And the QRPer waited for his answer until the Old Timer spoke again. "It may not be, but they believe. And what does it really matter?" And we had to leave it there, for nostalgia is the warmth of the old ones and the years will bring to everyone, eventually, the recollection of the good days that were, and a thought of some things that might have been, but never were. Always somewhere there will be someone whistling "Roses are Blooming in Picardy." And always next year will be the Big DX Year. ■

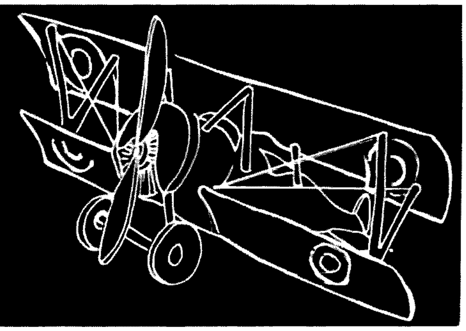
Autobiography of an Ancient Aviator



W. Sanger Green
1379 E. 15 Street
Brooklyn NY 11230

For a couple of months now I've been promising to tell you about an outstanding hunting trip that it was my privilege to be on. So here's the story.

In early November, 1928, Belin DuPont of Wilmington, Delaware, invited Bob Hewitt, (manager of the Ludington Philadelphia Flying Service), Victor Dallin (aerial photographer), Jack Thropp (manager of Trenton Airport), John Steffin (Philadelphia businessman) and myself for a week of hunting at the DuPont Combahee Plantation in South Carolina. As I remember it, the plantation consisted of about 10,000 acres situated near the mouth of the Combahee river, about halfway between Charleston (of horse diaper fame) and Savannah. Bob Hewitt made arrangements with Townsend Ludington for the use of his flying service's new six passenger Travelair for the trip. We were scheduled to depart on Saturday, November 24th, but, due to my late arrival that day from my trip to Wichita, our departure was postponed to Monday. So Monday morning we loaded our gear and cut cards to see who would drive to Raleigh on the first leg of our 600 mile trip. I cut the high card so we got under way. The weather was cold with rain and sleet, but the weather report was for warmer temperatures to the south. However, a few minutes after takeoff we began to take on quite a little ice. By that time we were nearer Bellanca Field (near New Castle, Delaware) than Philadelphia, so I set the ship down there. We had so much ice onboard that I had to land at about half throttle. The Bellanca boys put our ship in their heated hangar, so in about an hour the ice melted off. Also, weather had improved considerably, so we were on our way again. The rest of the trip was routine. The plantation had its own landing strip, which was well marked. We made it just before dark.

Combahee Plantation was beautifully organized for hunting parties. There was a choice of deer, duck, quail or pheasant hunting. In the evening, after dinner, the guests would meet with the plantation manager and each plan his next day's hunting. Breakfast was at 0500, so the duck hunters could be in their blinds with their live decoys in place well before daylight and the deer and bird hunters could be in position. There were plenty of guides. One went out with each duck hunter, taking him to his alloted blind by boat, anchoring his live decoys in the proper places, retrieving the birds he shot, and bringing the hunter, bag and decoys back to the big house when the morning flight was finished. The deer hunters were posted along a trail, and beaters with whistles, horns and bells would form a chain and drive the deer toward the hunters. The field hunters each had a guide and a retriever. Gold plated hunting – What? The meals, of course, were marvelous. We were there for five days and arrived back at the Philadelphia airport on 1 December with some 18 quail and pheasants, 35 ducks, one small deer, and an unrepayable debt to Belin DuPont.

When I got to my week's accumulation of mail the next Monday, I found one letter from Washington giving me a $400 a year raise, and another one advising me that I was transferred to Kansas City as of 1 January 1929, to be in charge of the Central Region. I didn't like the idea of moving so far away from our farm in Bethlehem, New Hampshire and from all my friends in the East.

When the Ludingtons learned of my pending transfer, they offered me the job of building and managing an airport on land they owned near Camden, New Jersey. The salary they offered me was about double my Dept. of Commerce pay. In addition they offered to rent me a house they owned in Pennsauken, N.J. (near the airport site) for about half the going rate. So who could refuse? The frosting on the cake was that they would like to have me pinch hit as a pilot for the Ludington Philadelphia Flying Service when needed. I took my resignation to Washington as soon as I could get it off the typewriter.

Washington offered to let me stay at Philadelphia at the new salary, but I had to refuse. After all, the reason I joined them in the first place was to find a worthwhile job in commercial aviation.

First thing Ludington wanted me to do was to make an inspection tour of the more active airports in the U.S. and see how they were doing things, their problems, and get any ideas that would be of value in building Central Airport at Camden.

I was already familiar with the airports in my old territory and around New York, so I started my itinerary with a visit to Lt. Duffy at Buffalo Airport. Then, next day, on to Major Berry and his Cleveland Airport. Then I traveled by train at night and made one day stops at Detroit (Ford Airport), Chicago's Midway, and St. Paul Airport. While in Detroit I contacted a friend who was a "revenue agent." He very kindly drove me around and, before I left, gave me six bottles of very fine confiscated (he called it "liberated") Scotch. Those were prohibition years. Remember? I spent the weekend on the choo choo from St. Paul to Salt Lake City. Time to relax and get caught up on my reports. Not much to see at Salt Lake, so I caught the midday train for Oakland, California. Ed Mouton met me at the Oakland Airport and ferried me over to the San Francisco Airport at San Bruno in his "Deep de Com" plane. Roy Francis showed me around his 'port, bought me dinner, and put me on the train for Los Angeles. I spent the weekend looking in on C. C. Mosley at Grand Central, Maj. Barnitz at Inglewood and the L.A. Metropolitan Airport at Van Nuys. I only had two bottles of Scotch left by then, so I climbed on the rattler for Kansas City. A couple of days enroute and another two in K.C. and I was ready to go on to St. Louis.

While I was in K.C. I heard that air transportation to St. Louis was available the next morning. I can't remember the name of the carrier but I remember buying a ticket and being the only passenger in a 4 passenger Ryan. The ship had dual controls so I sat up front with the driver. He told me he had just started work for the line and that this was his first trip over that route. I told him that I had been over the route a couple of times the month before under similar conditions and I thought that, between us, we should have no trouble. I suggested that he take a 100° course until we came to the Missouri river then, if it was still snowing and the visibility wasn't too good we could follow the river right down to Lambert Field. That's what we did – and arrived a few minutes ahead of schedule.

I had a nice weekend in St. Louis. Those people certainly know how to entertain visiting firemen. In Cincinnati I caught up with a couple of old friends at Lunken Field: Ed Conerton and John Paul Riddle. Paul was running the airport and the Embry-Riddle Airline. Ed had landed the "Voice From The Sky" Fokker trimotor there the day before and the heavy sound equipment it carried was enough to break its back in landing. So I spent an extra day with them before climbing on the night sleeper for Philadelphia.

Next month: Building Central Airport and small airline flying.

Hunters' arrival back at Philadelphia Airport, 1 December 1928. Left to right: Vic Dallin, John Steffin, Bob Hewitt, Jack Thropp, Sanger Green. Photo by Dallin Aerial Surveys.

I/O EDITORIAL

BILLIONS ... BILLIONS!

It isn't often that we can see quite so clearly a new market that is inevitably going to burgeon. Usually, when you can see something like this coming, you can use the information to make some money ... like investing in Haloid just before it became Xerox. The coming explosion in computers ... which will dwarf the already well-known computer growth ... does not give us any clear insights into turning a fast buck, but it certainly can be used to advantage.

I've already suggested that amateurs, by virtue of their head start in electronics, will have a decided advantage if they want to get into the sales or service of small computer systems. This is still a bit in the future, despite the opening within the last few months of a couple dozen computer stores around the country. Right now most computer stores are serving hobbyists rather than small businesses. This is primarily because to date there are really no practical small business systems available, only hobby systems. But business systems will be along ... and shortly.

How much of a business will there be? I would think we could expect at least a $50 billion a year volume ... and that probably is conservative. When computers get down to the $250 to $500 range, and they will soon, you will be seeing them everywhere ... on every desk at school ... every desk in every office ... in every small business or store ... in every home. They will be used for writing letters (most of which will eventually go via cable or satellite), keeping records, ordering from the store, billing, keeping bank records, teaching, games, art, music composition, newspaper replacement, etc.

If you are not really interested in getting into manufacturing or sales, you may want to look for investment in firms which are getting into these fields. While it is still too soon to get even a faint idea of how the pioneers in the field are going to do, you could do worse than keep a good eye peeled for up and coming firms.

uP AND AMATEUR RADIO

For some reason I've had a lot less static about the coverage of computers in *73* than I expected ... less than when I got started on FM and repeaters some years ago. While I recognize that a great many readers understand the impact that computers are going to have on amateur radio, still I also realize that despite our efforts to keep the readership of *73* confined to active and progressive amateurs, some spark-forever types are bound to have infiltrated.

Just as many amateurs reacted violently to transistors, refusing for years to accept that they were here to stay (see the *QST* George Grammar editorials in the mid-60s). I expect this same reaction to the revolution microprocessors are bringing us. The idea of a small PC board with a few chips being able to replace very complex electronic systems is going to take some getting used to.

How can an old timer (of any age) get used to a tiny computer system which can be used to change typing into Morse code, into RTTY, for editing text to be typeset, for playing games, for teaching almost anything, for keeping a mailing list, for running a repeater, or for just about anything the mind can imagine? It is almost too big a step to really comprehend. Just by changing the programs in their computers, two amateurs can use their systems to communicate by Morse, RTTY with Baudot code, RTTY with ASCII code, or any other agreeable system. With a slightly different program the system will see what code is being received and cope with it automatically. Pity the old timer.

Since I'm as new at all this as you are, I'll be trying to bring you articles which will help us to learn ... and as I begin to understand more of what is going on I'll try to keep you in touch. These new, relatively inexpensive, computer systems are a quantum jump for us, so we've got our work ... and fun ... cut out for us.

CONVENTIONS

The computer hobby field is getting big enough so they are already starting to hold conventions. An unusually high percentage of the computer hobbyists seem to also be radio amateurs, so you might find an event like this fun.

The first such convention, run by MITS at their plant in Albuquerque, is scheduled for the end of March ... as this issue goes to press. I'm planning to be there and report on this convention. The next one is May 2nd in Trenton, New Jersey and is being organized by Al Katz K2UYH, a well known UHF pioneer and Oscar addict. I'll try to be there and report on that meeting, too. More than a thousand hobbyists are expected to attend. There will be manufacturers' exhibits, prizes, demonstrations of hobby systems, plenty of technical talks and a flea market. Write Trenton Computer Festival, Trenton State College, Trenton NJ 08625 for details.

THOSE BUGBOOKS

It would take two or three years to publish as much really good info on TTL circuits as is covered in the *Bugbook* series. The real pity of it is that all of the information in these fat books is utterly fascinating and *should* be published in *73*. This is just exactly the kind of material that every ham either wants to have or else should want to have.

Bugbook I starts right out with the basics of TTL circuits and chips, explaining how they work and how more complicated circuits are put together with the IC building blocks. The books are split about half and half ... theory and practical experiments which you can hook together and see work. The experiments use inexpensive test jigs and commonly available (and inexpensive) ICs.

Look, I can't tell you what to do ... if I could I would flatly insist that you get this series of books immediately and stop horsing around trying to avoid keeping up with progress ... and trying to save a buck by making do with a couple chintzy magazine subscriptions. Oh, I do the best I can to bring you stuff like this in *73*, but there is just too much and you need it now, not in the two or three years it would take for me to get the material separated into articles and published ... by which time it would probably be out of date.

Let me put it this way ... the whole series of four *Bugbooks (I-II-IIa-III)*, which costs $36.85, will take you from beginner through microcomputers, complete with the fundamentals of programming ... something you are going to have to learn eventually. This is a fun way to get into this, since it takes you step by step all the way through with experiments you can make.

If you want to be a cheapskate about this you can start out with the first two books for $16.95 and cover the TTL part of the digital experience. But be warned that I have no intention of letting up on you until you have the whole set and are able to read relatively sophisticated articles on microprocessors in *73* ... and know what you are reading.

The drops in hardware costs will come from a combination of the benefits of mass production ... note that you can buy a brand new black and white television set for under $100 as compared to a far simpler slow scan television monitor at $250 ... and further IC developments. One IC video generator will undoubtedly replace the 50 IC generators of today ... and soon.

Teleprinters probably won't be coming down as rapidly as TVTs, due to the mechanical complexity. They will be about as expensive as typewriters in all probability. However, it is quite possible that they will become obsolete if a simple system of developing hard copy directly from the TVT tube is worked out. Some TVT units already have a Xerox type of copy system, though they are not cheap.

When some sort of direct computer-to-computer communications system does develop ... possibly based upon the ultra-cheap late night telephone rates which would permit a computer to call any other and leave a "letter" which could be read at the recipient's convenience ... this might be the salvation of the forgotten consumer as far as mail delivery is concerned. It would at least get us away from those big thick envolopes full of brightly colored gasoline company offers of overpriced junk ... or would it? We may well have full color TVT systems and still find those darned junk mail offers filling our morning TVT screens. The more things change, the more they stay the same, to coin a phrase.

And will the chap with the "Plaid Box" of the future be able to dump mail into a hundred thousand homes in one night via Ma Bell's lines? ... and for free?

POSTAL DISASTER

With first class mail looking to go to 17¢ by next year and to around 25¢ in a couple of years beyond that, some viable alternative is a must. The post office is already spending money (though not in *73*) to try and get people to send letters as a result of the drastic drop in mail use brought on by the 13¢ letter. There is also talk of a three day postal week.

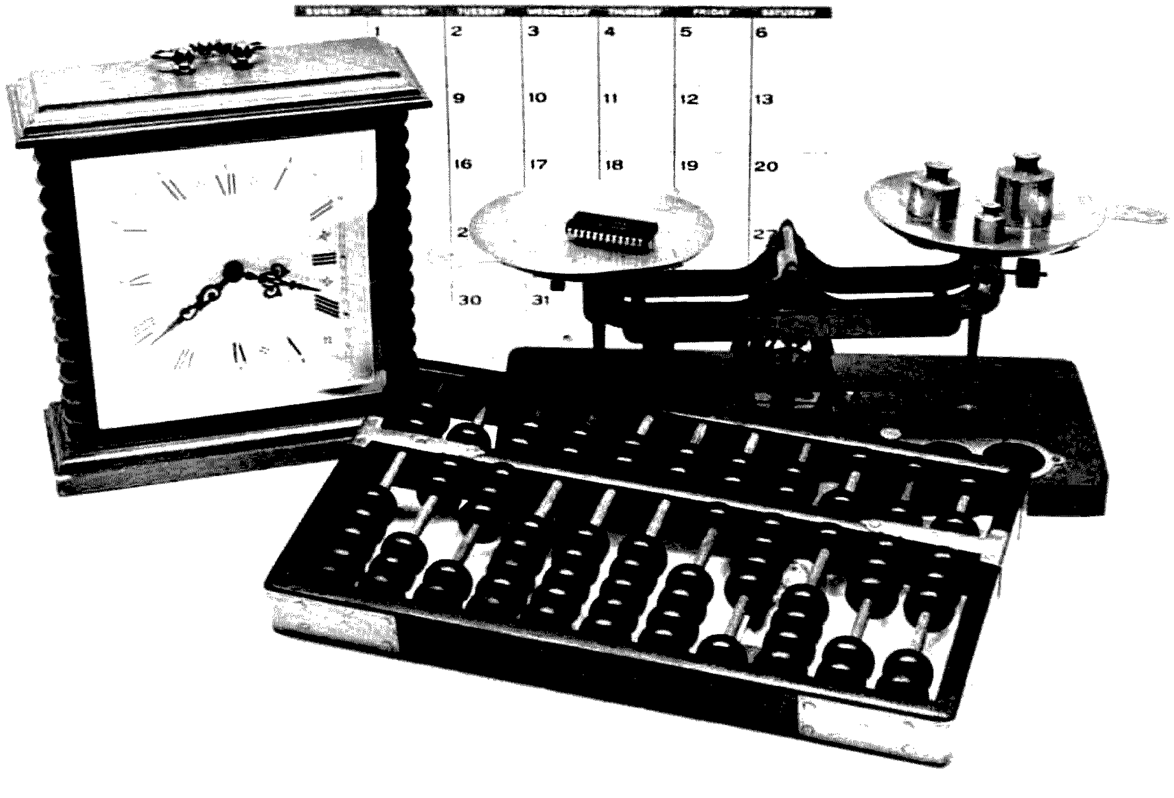
Two Finger Arithmetic

-- how computers figure



We are not aware of all the number systems we use daily, as represented by the items shown here.

The first caveman, when he learned how to count on his fingers, gave us the decimal number system which we use today. While this number system is second nature to us, it is not the only number system with which we come into contact every day. Timekeeping, for example, uses a unique numbering system which is based on the numbers 60 and 24. There are 60 seconds in a minute, 60 minutes in an hour, and 24 hours in a day. And of course, the English have blessed us with unique number systems for weights and measures — who can forget that 4 gills = 1 pint, 2 pints = 1 quart, and 4 quarts = 1 gallon? If you stop to think about it, you can see that we are involved with many number systems other than the decimal system.

The advent of the computer age has ushered in an additional number system, the binary system based on the number two. This system has come into common use since digital computers can represent information in one of two states — "on" and "off." These two states are called "binary" states and are the basis for the binary system which we use in digital computers.

Man commonly works with the decimal system, computers operate with the binary system, and the obvious questions are "How do we get from one system to the other?" And, "How do I represent information in a computer?" This article answers these questions and in addition explains how to do simple arithmetic in the binary system.

The Decimal System

We are constantly thinking numbers, adding numbers, and writing down numbers; but, do we really have an understanding of what we are doing? When we write down a number such as the number 3187, what does it really mean?

All numbers are made up of a series of digits. A number can have as few as 1 digit and is not limited to any maximum number of digits. In the decimal system, each place occupied by a digit has a power of ten associated with that place. For example, in the number 3187, we have four places. The powers of 10 associated with the four places are as follows:

digit	3	1	8	7
power of 10	10^3	10^2	10^1	10^0

The number 3187 could be written as the following sum:

$$3187 = 3\times10^3 + 1\times10^2 + 8\times10^1 + 7\times10^0$$

and if we remember our basic mathematics we will recall that

$$10^3 = 10\times10\times10 = 1000$$

$$10^2 = 10\times10 = 100$$

$$10^1 = 10$$

$$10^0 = 1$$

(By definition, *any* number to the zero power = 1.)

When we write the number 3187 we are saying that we have 3 thousands plus 1 hundred plus 8 tens plus seven units (or ones). Similarly, larger numbers such as 5197283 may be represented as

$$5\times10^6 + 1\times10^5 + 9\times10^4 + 7\times10^3 + 2\times10^2 + 8\times10^1 + 3\times10^0$$

The Binary System

Computers operate with the binary system because each digit can have only one of two states — "on" and "off." Numbers are represented in a computer by a string of binary digits called "bits." Consider a number represented by 4 binary digits (bits) when off = 0 and on = 1. Four lights may be used to display the "on" and "off," or one and zero respectively:

number	on	off	on	on
numerically	1×2^3 +	0×2^2 +	1×2^1 +	1×2^0

We know that

$$2^3 = 8 \qquad 2^1 = 2$$

$$2^2 = 4 \qquad 2^0 = 1$$

Our number represented by the lights above would be

$$1\times8 + 0\times4 + 1\times2 + 1 = 11_{10}$$

Instead of actually writing down lights to indicate the "on" and "off" states, we use the binary numerals 0 and 1. Thus in base 2 our number is written as 1011_2. If it is very clear that you are working with binary numbers, you may omit the subscript 2.

Conversion from Decimal to Any Base

Conversions from a given base to the decimal system can be made by expanding a number to the powers of its base (as shown in the previous section). But, how do we take a decimal number and convert that number to another base? The technique used for this type of conversion is the technique of successive remainders. As an example, convert the decimal value 43 to base two:

$2\overline{)43}$ = 21; 42; remainder 1 is the multiplier for 2^0

$2\overline{)21}$ = 10; 20; remainder 1 is the multiplier for 2^1

$2\overline{)10}$ = 5; 10; remainder 0 is the multiplier for 2^2

$2\overline{)5}$ = 2; 4; remainder 1 is the multiplier for 2^3

$2\overline{)2}$ = 1; 2; remainder 0 is the multiplier for 2^4

$2\overline{)1}$ (doesn't go) remainder 1 is the multiplier for 2^5

Our number expressed as powers of two is $1\times2^5 + 0\times2^4 + 1\times2^3 + 0\times2^2 + 1\times2^1 + 1\times2^0$ or 101011_2. Checking ourselves and converting back to decimal, $1\times2^5 + 0\times2^4 + 1\times2^3 + 0\times2^2 + 1\times2^1 + 1\times2^0 = 32 + 0 + 8 + 0 + 2 + 1 = 43$.

Binary Arithmetic

Arithmetic in the base two is very simple. You don't have to remember a lot of arithmetic facts; all you have to remember is zero + zero = zero, one + zero = one, and one + one = ten. As an example:

$$\begin{array}{r}1\\+0\\\hline 1\end{array} \quad \begin{array}{r}0\\+1\\\hline 1\end{array} \quad \begin{array}{r}0\\+0\\\hline 0\end{array} \quad \begin{array}{r}1\\+1\\\hline 10\end{array}$$

With binary arithmetic, whenever two or more ones appear in a column to be added there will be at least one carry bit added to the next left digit. For example, in adding

$$\begin{array}{r}11\\+\ 1\\\hline\end{array} \quad \text{right digit} \quad \begin{array}{r}1\\+1\\\hline 10\end{array}$$

carry bit

we get

carry → 1

$$\begin{array}{r}11\\+1\\\hline 0\end{array} \quad \text{and then} \quad \begin{array}{r}11\\+1\\\hline 100\end{array}$$

Storing Numbers in a Computer

When we talk about numbers stored in a computer, we don't normally speak of them in terms of bits (binary digits); we usually speak of them in terms of bytes or

words. A byte by definition is a collection of sequential bits. A byte can be any number of bits but is most commonly 8 sequential bits. A computer word is a collection of bytes and is defined as the number of bytes pointed to by one addressing operation in a computer. Words and bytes tell us about the organization of the computer. As an example, assume the standard definition of byte, where byte = 8 bits:

> The XDS Sigma 6 computer is a "32 bit" computer; it has 32 bits per word. 32/8 = 4, thus there are 4 bytes per word.
>
> The DEC PDP 11 series of computers have "16 bits" per word. It has two bytes per word.
>
> The INTEL 8080 microprocessor is an 8 bit microprocessor; it has 8 bits per word. Thus it has one byte per word.

The term byte is used very frequently as the definition for a unit of information. Alphanumeric characters (letters, punctuation, printable characters, etc.) are usually stored in coded form in "one byte."

Numbers written on paper are stored in visual form and for all practical purposes there is no limit to the size of the number on paper. In a computer, there are limits set, due to the "word size" and due to the arithmetic capabilities of the computer. In large scale computers, it is possible to work with very large numbers such as those which can be represented in 64 bits or more. In microprocessors, however, the limit is very small, usually being 8 bits but in some cases being 4 bits. The arithmetic capability that we are talking about is the type of arithmetic which can be performed in one computer instruction. It is possible to string instructions together and thus handle larger numbers. This is usually done by "software."

Computer Arithmetic

As previously mentioned, computers have limits set on their arithmetic capabilities. They cannot in a single instruction perform simple arithmetic on all size numbers; they are limited to performing arithmetic on some given number of bits. Because of these limitations, computer arithmetic is somewhat different from binary arithmetic. Computer arithmetic is binary arithmetic within limits.

A typical microprocessor, such as the Intel 8080, has 8 bit arithmetic capability. It can perform arithmetic on 8 bit numbers. It cannot in a single instruction operate on a 32 bit number.

The largest number that can be expressed in "8 bit arithmetic" can be determined as follows: Consider an eight bit binary number such as 11111111_2, all one bits in the eight bits. The number can be expanded as $1x2^7 + 1x2^6 + 1x2^5 + 1x2^4 + 1x2^3 + 1x2^2 + 1x2^1 + 1x2^0$, which is the same as $128 + 64 + 32 + 16 + 8 + 4 + 2 + 1 = 255_{10}$. This is the largest number that can be stored in a single 8 bit word (or byte) and also the largest *sum* that can be accumulated from the addition of two numbers. We can add $250_{10} + 5_{10}$ and get a sum of 255, but we cannot add 250_{10} and 6_{10} to give 256_{10}, since that sum is beyond the arithmetic capabilities of 8 bit arithmetic. Of course this arithmetic restriction only applies to a computer with 8 bit arithmetic. If the computer used 4 bit arithmetic or 32 bit arithmetic, then the actual largest number would be different. In a four bit arithmetic microprocessor, the largest number would be $1111_2 = 1x2^3 + 1x2^2 + 1x2^1 + 1x2^0 = 15$.

In order to simplify the examples, all discussion in this section will pertain to a microprocessor or computer with 8 bit arithmetic capability.

If our microprocessor can handle eight bit arithmetic and can also store sums up to 255, then what is to prevent us from attempting to add two numbers that will produce a sum greater than 255? The computer doesn't know what the sum will be before the addition, so we can at least make an attempt. The answer is, "Yes, you can instruct the computer to perform the addition, but the results will be wrong." An *overflow* condition will result. The storage capabilities and the arithmetic capabilities of 8 bit arithmetic will be exceeded. What happens is analagous to trying to pour 3 quarts of water and 4 quarts of water into a five quart container. The container will overflow.

Subtraction and Negative Numbers

Most microprocessors available today have subtraction capabilities; however, the microprocessor user may or may not wish to use those subtraction capabilities, depending on the capabilities available. The user may wish to "complement" the number to be subtracted and then perform an addition, so that the arithmetic techniques may be simplified. Two types of computer arithmetic will be discussed in this article – ones complement arithmetic and twos complement arithmetic.

Both negative numbers and subtraction are used in a computer, but not necessarily in the same manner as with pencil and paper. In order to indicate a negative, instead of writing down a minus sign on paper a "sign bit" is set to "one" somewhere in the computer. This "sign bit" may be stored in a word by itself or it may be stored in the same word in which the number is stored. Most commonly, the "sign bit," which indicates a negative number, is stored with the number itself in the leftmost bit position of the word. In an eight bit word, the sign bit would be as shown:

Sign bit x x x x x x x x

In a sixteen bit word the sign bit would still be the leftmost bit as:

Sign bit
↓
x x x x x x x x   x x x x x x x x

If the sign bit is a "0", then the number stored in the word is positive. If the sign bit is a "1", then the number stored in the word is negative.

The maximum range of numbers which can be represented in an eight bit computer would be as follows:

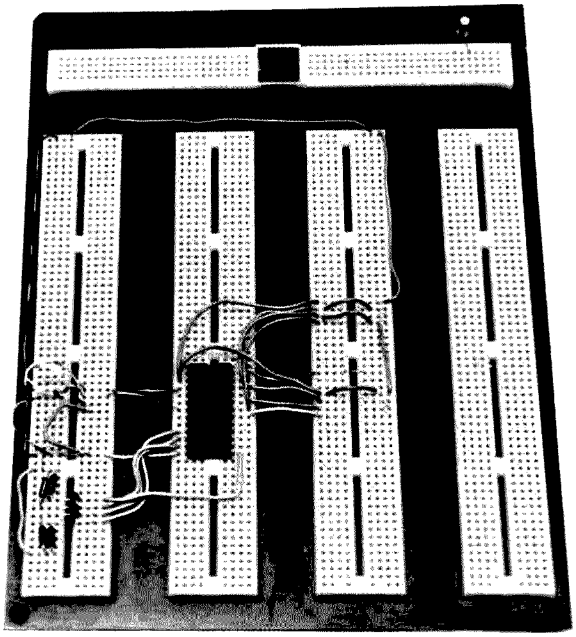
Sign bit
↓
0 1 1 1 1 1 1 1 = 127_{10}
(Most positive value)
0 1 1 1 1 1 1 0 = 126_{10}
.
.
.
0 0 0 0 0 0 1 0 = 2
0 0 0 0 0 0 0 1 = 1

0 0 0 0 0 0 0 0 = ZERO

1 1 1 1 1 1 1 1 = -1
1 1 1 1 1 1 1 0 = -2
.
.
.
1 0 0 0 0 0 0 1 = -127_{10}
1 0 0 0 0 0 0 0 = -128_{10}
(Most negative value)

In an 8 bit word we have defined one bit as the sign bit, leaving 7 bits for the data. This means that the largest number including sign that can be stored in an 8 bit word is 127_{10}. This puts a further restriction on arithmetic operations as can be seen by the example, 64 + 64.

	64 in binary	= 01000000
+	64	= 01000000
		10000000



"Hands on" experience in computer arithmetic using a 74182 IC will be the subject of the next article.

By definition, we now have a negative number! We have changed the sign of our number. As can be seen, the right combination of numbers added together will not produce overflow, but will change the sign. Thus, it is also important to test to see if the sign is changed when performing addition on numbers of like sign. If the sign has changed, the 7 bit capability has been exceeded.

In computer logic, it is easy to complement a word such that all ones become zeros and all zeros become ones. This capability is usually a standard feature within the arithmetic-logical unit of a microprocessor. The complement of the eight bit binary number 01001101 would be 10110010. The number 3 represented in 8 bits is 00000011, and the complement of three would then be 11111100. This type of complement where zeros are exchanged for ones and ones are exchanged for zeros is called "ones complement."

By complementing a number using the "ones complement," we have placed a 1 bit or a sign bit in the leftmost bit of the word, indicating that the number stored in the word is a negative number. A typical ALU will complement a word internally, and then perform addition in order to effect subtraction. This might happen as follows, for the operation 7-4:

7 in binary = 00000111

4 in binary = 00000100

The ones complement of 4 (negative 4) = 11111011. Adding the two together,

```
    00000111
    11111011
  1 00000010₂ = 2₁₀
  ↑
carry bit
(overflow)
```

But the answer is off by one and overflow has occurred. We got an answer of 2; the answer should have been three. This is the shortcoming of ones complement arithmetic, and is the reason all modern computers use twos complement for arithmetic operations and representing negative numbers.

Twos Complement Arithmetic

Twos complement arithmetic operations can be found in all present-day computers, from the lowly 4 bit microprocessor all the way up to the giant large scale systems. The reasons will become evident as we go on and see how effectively negative numbers can be represented in this form.

To find the twos complement of a number, take the ones complement of the number and *add 1*. For example, find the twos complement of 6:

6 in binary	= 00000110
ones complement of 6	= 11111001
add 1	1
twos complement	= 11111010

This value (11111010) represents a *negative six*. Therefore, we can say that when we take the twos complement of a positive number we are changing it to a negative value. To best illustrate that this value is in fact a negative six, let us increment it *six* times (up to zero):

11111010	Negative six
+ 1	
11111011	Negative five
+ 1	
11111100	Negative four
+ 1	
11111101	Negative three
+ 1	
11111110	Negative two
+ 1	
11111111	Negative one
+ 1	
1 00000000	ZERO

Carry discarded

Following are some examples of *subtraction* in twos complement arithmetic:

1. 6-5

5 in binary	= 00000101
ones complement of 5	= 11111010
add 1	1
twos complement	= 11111011

Summing,

6 in binary	= 00000110
twos complement of 5	= 11111011
	1 00000001

A carry is produced, but is discarded. The sign (most significant bit) is zero, indicating the result is positive.

2. 3-3

3 in binary	= 00000011
ones complement of 3	= 11111100
add 1	1
twos complement	= 11111101

Summing,

3 in binary	= 00000011
twos complement of 3	= 11111101
	1 00000000

And, the correct answer is, of course, zero.

3. 3-4

4 in binary	= 00000100
ones complement of 4	= 11111011
add 1	1
twos complement	= 11111100

Summing,

3 in binary	= 00000011
twos complement of 4	= 11111100
	11111111

The result is negative one in twos complement (no carry produced).

In twos complement arithmetic, the addition of two numbers of opposite sign will always produce the correct result. It may or may not produce a carry. The carry or overflow may be ignored.

Notice that, in both ones complement arithmetic and twos complement arithmetic, addition stays the same. The only thing that is changed is the way in which the complement is taken in order to effect subtraction. Some ALUs will compensate automatically for subtraction in ones complement arithmetic, while some won't.

In twos complement arithmetic, the programmer should test for overflow. In any addition of like signed numbers where there is a possibility that the maximum sum could be exceeded, a test must be made for overflow. If the test is not made, there is a danger that erroneous results could occur and that the user might not be aware of that fact. In reality, any addition could produce overflow. While the user may never expect overflow to occur, if his data were erroneous, then an erroneous sum could result. By making the test for overflow under all conditions, those errors "which couldn't possibly happen" would be detected.

All of the examples given here used 8 bit arithmetic to simplify the examples, but the principles and concepts discussed hold true regardless of the arithmetic word length used. On a 32 bit machine, larger numbers can be handled, but the test for overflow (carry) and change of sign must still be made.

Arithmetic Software

Binary arithmetic within a computer is not difficult or mysterious; however, care must be given to making sure that the results obtained from an arithmetic operation are correct. The care required can add additional steps to a program and can conceivably make a simple problem into a lot of work. One way in which some of the work can be eliminated is to choose a microprocessor which provides an automatic "hardware" scheme for testing for overflow or change of sign. Another solution is to choose a microprocessor which provides the same capabilities by software. Software in this case is a program furnished by the manufacturer to do the proper testing for you. This software may also offer the capability to work with 16 or 32 bit numbers and may in addition offer other capabilities such as multiplication and division.

The Next Step

This article avoided some of the more difficult arithmetic operations, such as multiply and divide, in order to dwell on some of the fundamental concepts needed to get "on the air." Multiply and divide can wait for later. If they are needed now, the user can perform successive additions or subtractions as required, or he can use software provided by the manufacturer. These functions will be covered in a later article. It is important at this time to give the experimenter "hands on" experience with computer arithmetic so that experience and confidence can be built up. For this reason, the next article will describe simple experiments with computer arithmetic using a 74181 Arithmetic Logic Unit. These simple experiments will use the concepts discussed in this article and will help the experimenter to better grasp computer arithmetic. ■

Those Exciting

Assistant Editor

Data processing systems have revolutionized our world, allowing vast amounts of information to be stored, exchanged, updated, and utilized in ways undreamed of a few years ago. A chain of department stores can be tied together, for example, by a data network making current inventory, personnel and credit information instantly available at widely separated locations; a railroad can control activity at its switchyard from a control center hundreds of miles distant; switching functions within a telephone company office can be accomplished rapidly and reliably in accordance with stored program instructions. The information involved in each of these examples is different, but the underlying processing principles are the same.

A digital computer or data processor of any type is basically a stored-program machine, in which a memory facility holds a set of operating instructions — the system program. Information is put into a digital format and fed into the machine, which retains it in a data memory. The instructions in the program memory, which are also in digital form, tell the processor what problem is to be solved, or function performed, related to the input data. When the operations demanded by the program memory have been completed, the data is fed out to be utilized in some manner. In practice, program instructions are often stored within the same memory facility as the data; in this way, the program can also be changed if desired.

Despite surface differences, the ways in which memory facilities receive, hold, and feed out information are all based on either sequential or random access principles.

Sequential Memories

The sequential, or serial, memory method requires that the data bits comprising the information be arranged in a particular order. Data stored in this manner — including both programmed instructions and input information — is retrieved strictly in accordance with its position in a time sequence.

A simple example of sequential memory storage is paper tape, which uses the presence or absence of holes to indicate the condition of a data bit; the combined states of several bits identify a particular digit (see Fig. 1). The tape is moved through a sensing device to convert the hole patterns into a series of pulses for electronic processing. Each piece of information is retrieved as it passes the sensor. Another form of sequential memory storage is magnetic tape, which stores information as magnetic flux variations corresponding to the 1s and 0s of digital data.

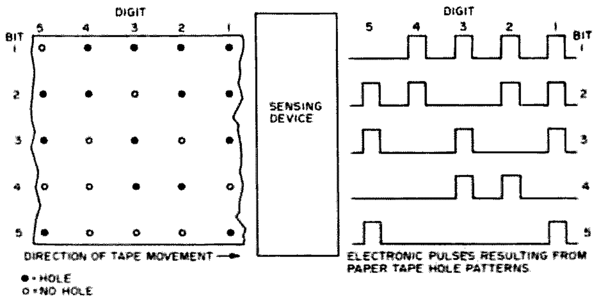

Fig. 1. Paper tape is a form of sequential memory storage, in that the bits identifying a given digit can only be retrieved during their allotted sensing time, which may cause delay in finding desired data.

Sequential access memory systems, including punched cards and magnetic disks as well as tapes, have been widely used in the area of mass computer memories. They typically contain program instructions and must be physically introduced into the processor system — threaded through a sensing device, for example — so that input data can be operated upon. They may also be used to retain the data for future processing. These devices provide a permanent storage capability since the cards, disks, and tapes can be removed and filed for repeated use, and they have non-destructive readouts (i.e., data does not have to be re-entered every time it is used); however, they have some shortcomings which limit their usefulness in high speed memory applications.

For example, sequential access can be a relatively slow process because a large amount of irrelevant data may have to be scanned before the desired bits are found. This delay may be from milliseconds to minutes, which is much too great for many of the uses to which modern data processing equipment is put. Additionally, these sequential

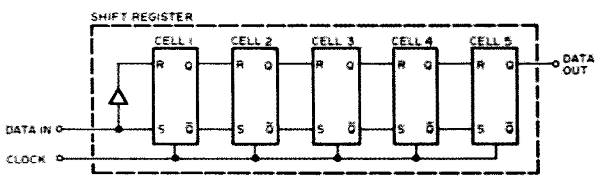

Fig. 2. The shift register, which stores data for as long as it takes for the clock to move it through each cell, is typical of semiconductor sequential memory systems.

Reprinted from the *GTE Lenkurt Demodulator*, September, October, 1975.

mass memory systems require a mechanism to move the data-carrying medium past the sensor; this device is of necessity completely mechanical, and is subject to the adjustment and maintenance considerations which apply to all such devices.

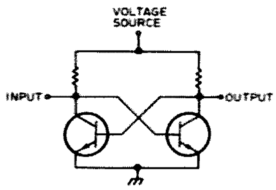

Fig. 3. The bistable multivibrator, or flip flop, has two stable states, making it an ideal digital data memory storage cell.

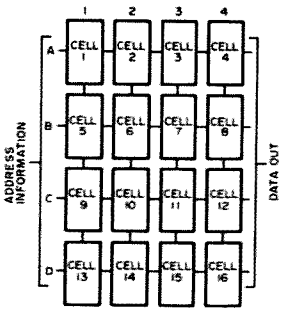

Fig. 4. A random access memory (RAM) is a matrix of memory cells, any of which can be accessed without regard for any other cell.

Memory Chips

-- RAMs, ROMs, PROMs, etc.

Temporary Memories

Cards, tapes and disks continue to play an important role as high density, long-term mass memory storage elements in such applications as personnel record maintenance, inventory control, and retention of performance data for comparison with future achievements.

For low capacity, temporary memory storage, however, structures composed of semiconductor devices have become dominant in recent years. Temporary data storage facilities are used in such areas as office equipment (calculators, etc.) and immediate-use or "working" memories wherein a data processing device can hold the data with which it is dealing at any given time. It is not uncommon for a data processing system to use tapes and similar elements as permanent, high volume program storage facilities, and semiconductor structures for the "working" memories in which the stored data is operated upon.

Temporary memories are also widely used in data processing terminals, which serve as remote input/output units for a large central computer and may be in any number of forms, from a simple typewriter keyboard to a small computer. Terminals provide a means of encoding data for manipulation by a central computer, and decoding it for use by a human operator.

Interconnection of central computer and remote terminal is commonly made over telephone lines through an interface unit called a modem, or data set. The data set may also contain a temporary memory facility which allows it to hold data and either condition it for transmission over the lines or prepare received data for application to the processor.

The semiconductor devices used in temporary memory structures are typically arranged as groups of individual units called memory cells, each of which stores one bit of information as either a logic 1 or logic 0. A cell may consist of as little as one transistor-capacitor combination, or it may be a complex arrangement of several components. But, whatever its composition, it has at least two states that can represent digital data bits.

Shift Registers

A shift register is a device for the temporary storage of digital information; when a shift, or clock, pulse is applied, the register accepts new data and moves every stored bit one step toward the output.

Fig. 2 shows an example of a semiconductor shift register containing five memory cells, each of which is a solid state reset-set (R-S) flip flop circuit. Data applied to the register input in a digital form is stored and shifted from cell to cell in accordance with the clock cycle rate. A logic 1 on the S input of cell 1, for example, will set the flip flop to the 1, or "on," state if a clock pulse is present at input C, thus storing the digit. On the next clock pulse, the stored bit is shifted out of cell 1 to set the second cell to the 1 state, and a new digit is fixed in the first cell. This procedure continues through the register, with the output of the final cell being shifted out for data processing. The clock frequency controls the rate at which the shift register stores and feeds out data bits, with each bit being delayed between input and output by as many clock cycles as there are cells in the register. Since the storage and retrieval are done on a first-in, first-out basis, the shift register is a sequential memory storage device.

Digital data can also be handled by a random access process. This does not mean, of course, that no orderly procedure is involved; it means, rather, that information can be stored in a partic-

ular memory cell, or location, and retrieved without regard for any other location.

Random Access Memory Systems

A random access memory (RAM) can be defined as a structure in which any data bit can be stored (written) or retrieved (read out) in any order.

One of the most basic ways to create a memory cell is through the use of the bistable multivibrator, or flip flop. As shown in Fig. 3, such a memory cell may consist of only two transistors, two resistors, and a power source. In this cell, one or the other of the transistors is always conducting, holding the other one off. When an external signal forces the off transistor into conduction, the initially on transistor turns off and remains in this condition until another external signal resets it. The flip flop, therefore, has two stable states which can be used to store information in the form of logic 1s and 0s.

A RAM is essentially a matrix of such memory cells, with each cell identified by a unique code, or address. The data processing equipment can retrieve a bit of information by addressing the proper location. Because of the matrix structure, the time required to locate any given bit is approximately the same as that required to locate any other bit. For example, in Fig. 4 the digit stored in cell 1, at location A1, could be available at the data output in almost exactly the same time as the bit in cell 16, location D4. This rapid access to information makes the RAM ideal for application as a temporary storage facility.

Random access memory structures are of two basic types: read/write and read only. A read/write RAM is programmable; that is, data can be entered into, changed, and removed from the memory at any time. A read

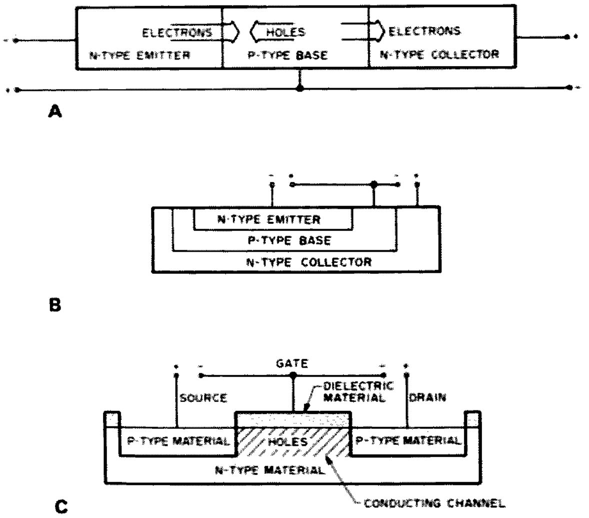

Fig. 5. Bipolar and unipolar transistor structures are the most widely used semiconductor memory cell components.

only memory (ROM), however, has certain data patterns fixed into it, usually during the manufacturing process. In such a structure, information can be read out – it will always perform the same function – but the stored program does not change. Because the data pattern is fixed, a ROM retains its program regardless of circuit power considerations; that is, it is a "non-volatile" memory device. A read/write memory, however, needs a constant source of power to remain in operation; if power is removed, the semiconductors stop conducting and the stored information is lost, so the read/write RAM is considered to be a "volatile" device.

Although it is not technically accurate to do so, common usage has led read/write memories to be referred to simply as RAMs, while read only structures – which are, in reality, a type of RAM – are designated ROMs, and this discussion will follow the same nomenclature.

Bipolar and Unipolar Transistors

The two most widely used devices in memory matrix design today are the bipolar and unipolar, or field effect, transistor. Each can be easily realized as an integrated circuit (IC) component, and they are readily adaptable to virtually any circuit configuration.

Essentially, a bipolar transistor is a semiconductor device whose conductive properties depend upon both majority and minority carriers; that is, current flows in a bipolar transistor because of the simultaneous movement of both positive and negative charges. Negative charges predominate in n-type semiconductor material because there is a surplus of free electrons within the material's atomic structure; p-type material, however, has a shortage of free electrons. The regions in which the electrons would normally exist act as positive, mass-bearing charges called "holes"; p-type material thus maintains an excess of positive charge carriers. The common transistor is a general type of bipolar device, since its current flows due to hole and electron movement. Fig. 5A shows the normal flow pattern within an NPN structure (Fig. 5B shows a bipolar NPN structure as an integrated circuit). The forward-biased emitter-base junction allows electrons to be injected by the emitter into the base region. Within the base, the greater part of the current flow is caused by holes combining with the excess electrons. The reverse bias of the collector-base junction allows electrons to pass into the collector region; because there are two n-type regions, electrons are the majority carriers, although the simultaneous action of the minority carrier holes is indispensable.

The field effect transistor (FET) is a unipolar device, in that its current flow is the result of the movement of only one type of carrier. In what is called the p-channel FET, holes are the majority carriers, while the carriers in an n-channel FET are electrons.

Fig. 5C shows a p-channel FET structure operating in the enhancement mode, which is the most common operating mode for FETs. In this mode, there is no conduction within the device when the gate voltage is zero; the other mode of operation is called depletion, wherein the semiconductor device is always conducting and requires a proper gate-to-source voltage to turn off.

When the gate in Fig. 5C is made negative with respect to the source, it creates an electrostatic field which attracts holes from the n-type semiconductor material toward the area directly below the gate dielectric material. Initially, this n-type area has a surplus of electrons, but as the holes are drawn into it, the electrons are neutralized. At some gate voltage, the holes become dominant and a current-carrying channel is produced between source and drain in which holes are the majority carriers. Because the gate is electrically isolated from the rest of the structure by the dielectric material, there is no current flow into it; the channel, which allows current to flow between

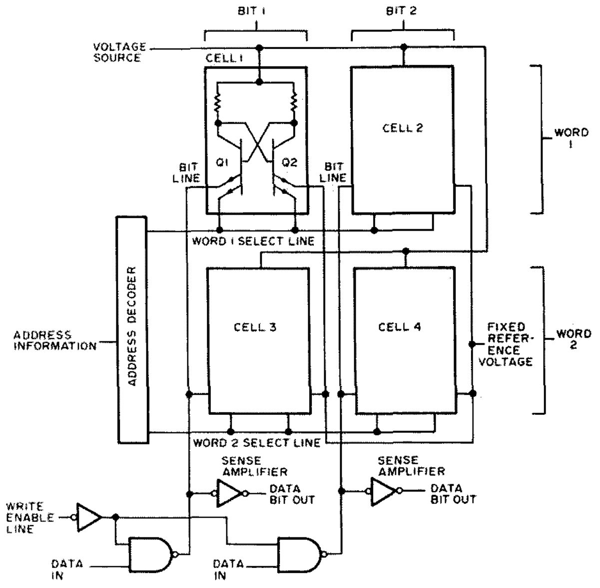

Fig. 6. A 2-word, 2-bits-per-word memory array utilizing multi-emitter bipolar transistor structures.

source and drain, is created and maintained by the electrostatic field.

The need to provide more electronic function in increasingly small areas has resulted in a great variety of miniaturized circuits. Bipolar transistors, for example, can be realized as discrete items, such as those seen in various entertainment products. In data processing applications, however, the large number of components required to produce a memory matrix makes the use of such bulky devices impractical; a circuit board with several hundred discrete transistors mounted on it – which is what a memory matrix would require – would be too unwieldy to be of any real use.

Bipolar Transistor RAMs

Integrated circuit techniques allow quantities of circuit elements to be realized in a small space; these techniques have been used to produce bipolar transistor memories of various microminiaturized sizes and densities.

The basic storage element in these matrices is the bistable flip flop, which appears in many circuit variations to meet different application requirements.

A bipolar RAM cell which has been widely used is the transistor-transistor-logic (TTL) type, exemplified by the multiple-emitter circuit (see Fig. 6). In this case, the data processor applies an address code to a decoding circuit; the decoded address raises the voltage on the correct word select line (places it at a logic 1 level), preparing the cell for the read or write function. A logic 1 bit can be written into the cell, for example, by placing the write enable line at a low voltage (logic 0) level while the data bit input is logic 1. This causes the bit line to be low, turning Q1 on and Q2 off, a state which represents a logic 1 within the cell. Once the write function is complete, the address changes, the word select line returns to a logic 0 state, and Q1 remains on. To read out the stored digit, the address raises the word select line level and the write enable line is held high (logic 1), allowing read current representing the value of the cell's contents to flow into the appropriate sense amplifier for output to the data processor. Because the read process does not change the state of the flip flop, the stored information is not lost and the cell is considered to have a "nondestructive" readout capability.

The 2-word, 2-bits-per-word memory shown in Fig. 6 is, of course, limited in its application. The same addressing, reading, and writing functions, however, are performed in bipolar RAMs containing several times the number of cells. A typical example of expanded capacity is a single integrated circuit capable of storing 16 words of 4 bits each, for a total of 64 bits on one tiny silicon chip. GTE Lenkurt uses nine such chips in both its 262A and 262B data sets. The bipolar RAMs comprise a data memory, in which input data is held to be operated upon. Because of the read/write capabilities of the RAMs, the data being processed can constantly be updated and changed.

Major considerations in memory design include the speed with which a cell can be made to change state (access time) and the amount of power dissipated by the cell's components.

Operating in a saturation mode – in which the "on" transistor constantly conducts the maximum possible current – the TTL-type memory cell requires some amount of time to drive the transistor out of saturation before a change of state can occur. This delay is only on the order of nanoseconds, but is enough to concern circuit designers. In addition, the saturation mode consumes relatively large amounts of power. Two of the more successful configurations developed to overcome these disadvantages are the diode coupled and emitter-coupled logic (ECL) cells.

Diode Coupled RAMs

Two gating diodes are used to control conduction in a diode coupled cell (Fig. 7). In integrated circuits, these diodes are frequently "hot-electron," or "Schottky barrier," devices, which become forward-biased at lower voltages than conventional diodes.

If the state of a cell must be changed to store a bit, the address decoder causes the voltage on the word select line to be forced low, while the voltage is raised on the bit line associated with the transistor to be turned off. Referring to Fig. 7, in which Q2 is hypothetically to be turned off, raising the bit line B voltage and dropping the word select line (effectively making it more negative) draws additional current through R4, increasing the base voltage on Q1 to the point at which it begins conducting. The cross-coupling of the transistors then causes Q2 to turn off, thus effecting the cell's change of state.

Reading the stored digit out of a diode coupled cell also requires that the word select line be forced low, but in this case there is no voltage increase on either of the bit lines. The combined effects of the lowered word select line and a bias network cause the diode associated with the "on" transistor to be forward-biased, causing the diode to conduct. Since the diode associated with the "off" transistor is reverse-biased, a differential voltage develops between the bit lines. A sensing circuit determines the cell's logic state from this voltage.

Read current in a diode coupled cell is greater than standby current, which flows when the cell is storing a bit without being addressed, but is substantially lower than write current. Because of this, the voltage developed across the load resistors during the read operation is not great enough to change the cell's state and the readout is a nondestructive process.

Since standby current is lower than read current and is present a greater percent of the time, overall power consumption in a diode coupled cell is lower than that of a TTL device.

ECL RAMs

The structure of emitter-coupled logic (ECL) memory cells closely resembles that of TTL cells, but biasing techniques are used to keep the transistors out of saturation. This allows the ECL storage element to change state very rapidly; the greatest advantage of ECL over other semiconductor memory configurations is that it has the shortest access time of all. Reading and writing processes are accomplished in essentially the same manner as for TTL, but at a greater speed. Because it constantly draws high current, however, an ECL memory cell has even higher power consumption than TTL, a fact which does impair its usefulness in certain applications.

MOS Technology

One of the major objectives in semiconductor memory design has been to incorporate as much capacity as possible in the smallest area. The greatest size reductions have been achieved with metal oxide-silicon (MOS) techniques, which produce field effect transistor (FET) structures that are considerably more compact than the bipolar integrated circuits (ICs) previously discussed.

An MOS FET is formed by depositing an insulating metal oxide – most often silicon dioxide – on a chip of silicon. Etching processes then remove the oxide from selected areas of the chip, exposing the substrate at source and drain locations while leaving the gate region insulated. Further processing establishes n- and p-type areas within the substrate.

The size reduction possible with MOS techniques allows a much denser memory array to be produced within a given space than is possible with bipolar devices; there are also substantially lower power requirements and reduced packaging costs.

Storage cells composed of MOS FETs may be of either a static or dynamic nature. A static cell retains its stored data as long as power is supplied to the circuit; a dynamic cell depends upon capacitive charge storage to hold its data, and must receive a "refresh" input to counteract the effects of leakage.

Static MOS RAMs

The basic static MOS RAM cell is a bistable multivibrator (see Fig. 8) closely resembling the bipolar flip flop used in TTL memories. In an MOS flip flop, however, transistors serve not only as cross-coupled inverters (Q3 and Q4), but also as load resistances (Q1 and Q2). Electrical isolation of the FET gate results in a very high input resistance which can be controlled by the gate voltage. A large-value resistor can thus be produced by an FET in a relatively small space compared to a conventional resistor.

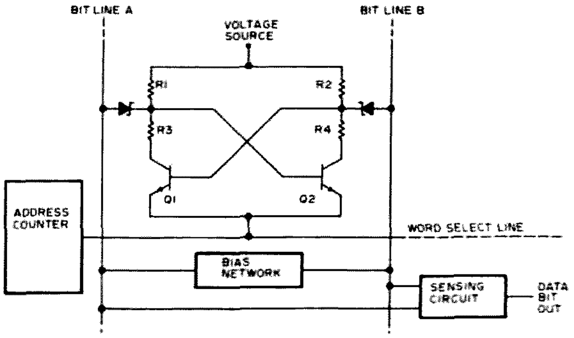

Fig. 7. A diode coupled memory cell uses gating diodes to control conduction and reduce power consumption.

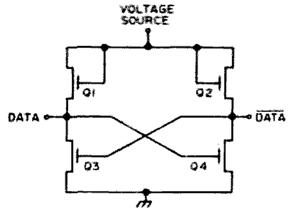

Fig. 8. The heart of the static MOS RAM storage cell is the bistable flip flop composed entirely of field effect transistors (FETs). The logic level at one terminal is always the complement of that at the other.

Since only one of the cross-coupled inverters conducts at any given time, the cell has two stable states which can be used to store information in the form of logic 1s and 0s. The state of the cell is determined by external address and data signals. The cell's state remains constant unless changed by an external signal, so no refresh action is required and the circuitry needed to support the operation of the cell is simplified.

A static MOS RAM storage unit, however, contains a minimum of four transistors, so it occupies a considerable amount of space on a silicon chip and consumes a relatively large amount of power. Because of these disadvantages, static devices have been largely replaced by dynamic MOS RAMs.

Dynamic MOS RAMs

The basic storage element in a dynamic MOS RAM cell is a capacitor, which holds and releases a stored charge in response to read and write commands. While the capacitor could be an external device, it is much more common for dynamic RAMs to utilize the capacitance existing between gate and source of the MOS FET itself. This capacitance is due to the isolation of the gate from the rest of the structure by a dielectric material. Charging the gate-source capacitance sufficiently to turn the transistor on represents a logic 1 state in most applications, while a lower charge or no charge at all serves as a logic 0.

Inevitably, as with all capacitive devices, the charge stored in the gate-source region drains off due to leakage current. If the charge is allowed to deteriorate too much, the data bit is lost, so some means must be provided to periodically restore, or refresh, the charge; a common requirement is that every cell in a memory matrix be refreshed every 2 milliseconds. Circuits to accomplish this are included in dynamic RAM designs, as are address decoding circuits.

The operation of a typical dynamic MOS RAM cell can be illustrated with the 3 transistor cell shown in Fig. 9. In this case, information is stored as a charge in the gate-source capacitance (C_G) of transistor Q2. To write a data bit into this cell, an address decoder produces a write select signal, activating transistor Q1 and allowing data on the write data line to be transferred to the storage element. Depending upon the state of the data input, C_G either charges or is discharged. When the write select signal is removed at the end of the write cycle, the bit is held in the cell.

At the beginning of a read cycle, both the read and write data lines are preset to some voltage. When the address decoder produces a read select signal, Q3 is ready to begin conducting. If the charge on C_G is sufficient (logic 1), Q2 turns on and current flows through Q2 and Q3, reducing the voltage on the read data line. With no charge on the capacitance, Q2 and Q3 remain off and the read data line stays at its preset level. Because of the gate isolation, C_G is in the same condition (charged or discharged) at the end of the read cycle as at the beginning, making the read process "nondestructive." An output amplifier senses the state of the read data line and determines what cell condition would produce it (a low-level line generally indicates a stored logic 1) for application to the data processor.

Refresh

Refresh of the stored digit in Fig. 9 is accomplished through a clocked amplifier connected between the read and write data lines. Control circuitry provides the timing necessary to keep the refresh cycle separate from the read and write operations.

The refresh process involves reading out the stored digit and writing it back into the cell. To do this, both data lines are preset at the beginning of the refresh cycle. A read select signal is then produced, transferring the bit to the read data line in the same manner as the normal read operation. The refresh amplifier inverts the condition of the read data line and applies it to the write data line. A write select signal then replaces the read signal and the data present on the write data line is entered into the memory. If, for example, a logic 1 (maximum charge) is stored on C_G, the read data line is forced low (logic 0) when the read select signal forces Q2 and Q3 into conduction. The refresh amplifier inverts this and applies logic 1 to the write data line; the presence of the write select signal causes this data to be written into the cell as a refreshed bit. With no charge (logic 0) on C_G, this sequence is repeated, with a logic 0 appearing on the write data line to ensure that the capacitance is not charged by stray circuit currents.

In Fig. 9, timing from the control circuitry allows a single amplifier to serve an entire column of cells. One alternative configuration uses a common read/write data line. This lets the cell form a loop within itself and thus eliminates refresh amplifiers.

ROMs

A read only memory (ROM) is a data storage facility into which information is normally written only once. After this entry, a ROM always produces the same output when addressed.

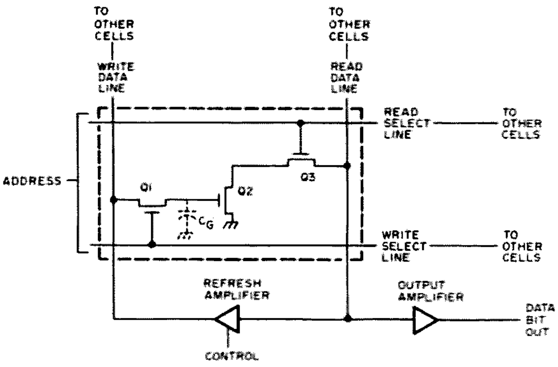

Fig. 9. A dynamic MOS RAM cell stores data in the gate-source capacitance of one of its transistors.

The difference between the read/write RAM and the ROM can perhaps be best illustrated with the example of the pocket calculator. In almost all calculator designs, a RAM matrix serves as a "working," or data, memory and ROMs are used for input/output interface, timing control and program storage (see Fig. 10).

Each key on the calculator keyboard is identified by a unique binary number; all of these numbers are permanently fixed in the ROM encoder so that, when a key is pressed, the corresponding binary number appears as the encoder output. If a digit key is pressed, the bits comprising the number are written into the RAM data store. Function key (addition, subtraction, etc.) numbers are applied to the ROM program store as addresses. In the program store are contained instructions for each function; when an address is presented, the proper instructions are read out of the ROM, leading to performance of the desired operation upon the data held in the RAM. When the function has been completed, the result is read out and applied to the decoder, which puts it into a form suitable for display.

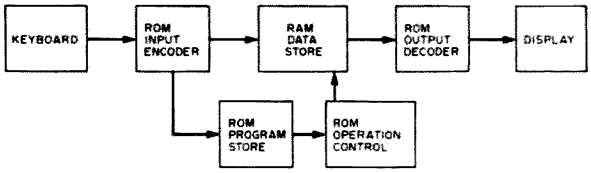

Fig. 10. A pocket calculator typically utilizes both RAM and ROM facilities to process input data.

The basic ROM structure is a matrix of elements, each of which is accessed by a random address code, allowing approximately equal access time to all bits. The simplest ROM structure is a network of diodes wherein the presence or absence of a diode determines the logic state of a particular location; such a network is shown in Fig. 11. The row address decoder raises the voltage on the appropriate word line to a high positive level, forward-biasing the diodes attached to that line. When the diodes begin conducting, they force their associated bit lines to a high (logic 1) level, while bit lines not connected to diodes remain low (logic 0). Output amplifiers sense the state of each line and present the bits to the data processor's other circuitry.

For example, if the row address decoder raises the word line 1 level, diodes D1, D2, and D3 conduct, raising bit lines 1, 2 and 4. In this case, the matrix output would be the binary number 1101. The next address might raise word line 4, in which case the output would be 0110. In some applications, column (bit line) addressing is added to select fewer than the maximum possible bit outputs.

ROM matrices are also formed with bipolar and MOS devices. In the most common configurations, the presence or absence of conductors establishes logic states.

Fig. 12 shows a ROM matrix utilizing multiple-emitter bipolar transistors. In this case, the collectors are used as row enabling contacts, replacing the word lines, and emitter contacts are omitted from selected locations to set logic levels. When the row address decoder raises the voltage on the appropriate collector to a

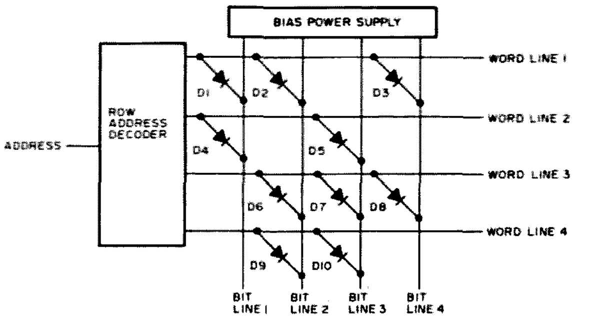

Fig. 11. A diode network with random access addressing is the simplest type of semiconductor ROM.

sufficiently high level, the transistor segments with emitter contacts begin conducting: for example, if Q2 is selected, the matrix output is 1001 (the level of columns 1 and 4 raised by conduction, 2 and 3 remaining low). In Fig. 12, column address and data output decoding selects two of the four bits for application to the processor.

In Fig. 13, a ROM matrix composed of static MOS FET devices is shown. Logic states are determined by the presence or absence of gates within the transistor structures. Reading this memory is accomplished in the same manner as diode and bipolar ROMs, except that the bit lines are driven low (to ground) when the FETs conduct.

Programmable ROMs

Semiconductor memories are almost universally formed on minute silicon chips capable of holding large numbers of integrated circuit devices; the chips often contain complete addressing, decoding, and output circuitry in addition to the memory cells.

In the formation of standard ROM matrices – in which the stored data is never to be changed – logic states are established during the manufacturing process by omitting the proper elements to create the desired bit pattern. This is the most prevalent type of read only memory. There are cases, however, in which standard memories are not available to meet application requirements, so programmable ROM (PROM) matrices are also produced.

A PROM is essentially a semiconductor matrix which has its program written into it at some time other than the manufacturing process. The manufacturer provides a chip on which all of the rows and columns (word and bit lines) are linked by conducting devices. Before integrating the chip into a circuit, the purchaser of the PROM uses various techniques – from application of a high-level write current to a laser beam – to eliminate devices from the matrix. In this way, a stored program unique to a given application can be produced.

New Developments

This discussion has covered structures that are representative of devices currently used in data processing memory facilities, and has not attempted to consider all of the variations of the basic structures. Advances are being made at a remarkable rate, and today's technology may be totally obsolete in a few years. Among the new memory devices that may bring this about are charge coupled devices (CCDs), bucket brigade devices (BBDs) and magnetic bubbles. Charge coupled and bucket brigade devices are similar in that both store digits as the presence or absence of electric charge.

A basic CCD is a semiconductor chip – either n- or p-type – over which a dielectric material is laid. A series of gate contacts are placed along the dielectric. Charge is stored as minority carriers under the gate regions. When the substrate is p-type, for example, applying a positive voltage to one gate attracts electrons out of the substrate until they dominate in the area directly beneath the gate, forming a "potential well." This storage condition is maintained for times up to several seconds after the gate voltage is reduced. Raising potential on the next gate in the series forms a second potential well into which the stored charge is transferred; gate potentials are sequentially raised by a clocked voltage to move the stored bit through the device. The CCD is thus a sequentially accessed memory facility similar to the shift register.

The movement of charge in a bucket brigade device is the same as in the CCD. Potential wells, however, are replaced by "buckets" of material unlike the substrate; for example, n-type areas may be embedded beneath the gates in a p-type chip to act as MOS storage capacitors.

Fabrication techniques currently limit the production of CCDs and BBDs, but they hold the promise of extremely small, very fast, low power memories of high density, and many manufacturers are investigating their commercial feasibility.

Magnetic bubble technology is still in the developmental stage, but it also shows great promise. The bubbles, which are tiny, mobile particles whose polarity is opposite to that of the thin film containing them, can be arranged to form coded data patterns, thus providing a storage medium.

Conventional bipolar and MOS devices are being modified to achieve an optimum combination of memory cell size, speed and power consumption. N-channel and p-channel MOS FETs are being combined on one chip as complementary MOS (CMOS) devices for low power applications, and Schottky diodes are being introduced into various bipolar configurations to decrease power consumption and increase speed. One such modification has resulted in the low power Schottky TTL memory cell, which has access speed approaching that of ECL (the fastest presently available cell type) and power requirements close to those of MOS FETs; GTE Lenkurt uses this family of devices in its 262A and 262B data sets to achieve the most rapid data processing possible with the least power. In another development, metal-nitride oxide semiconductors are being looked at as possible non-volatile read/write RAMs (memory facilities which

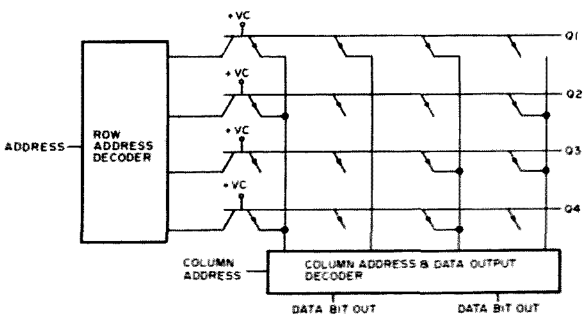

Fig. 12. Bipolar read only memory matrix.

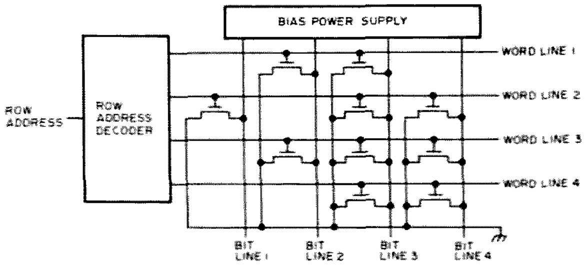

Fig. 13. The logic states within a static MOS RAM are determined by the presence or absence of gate contacts.

would not lose stored data when power is removed).

Whether improvements to existing structures continue at the present rate, or new technologies take over completely, there is no doubt that semiconductors will play an increasingly important role in data processing systems. ■

A Morse to RTTY Converter

-- using a microprocessor

The advent of powerful, inexpensive microprocessors has made the goal of a good Morse code to TTY translator a practical reality. Only seven chips are needed to implement this Morse code to Teletype translator which is self-adaptive to code speed and spacing over a wide range – without adjustment. Either ASCII or Baudot output is available by changing the programming ROM. Serial output is provided which can be adjusted from 60 to 100 wpm.

This translator will accept a dot/dash ratio from 1:2 to 1:4 (1:3 is nominal for International Morse Code) with any ratio of letter speed to spacing (i.e., 25 wpm characters spaced out for 10 wpm) because mark and space timing are evaluated separately. A speed variation of ±20% per character can be followed without error. Larger variations require from three to ten characters at the new speed to regain lock. Word spacing is also provided, and carriage return is adjusted to avoid breaking up words at the end of lines.

Due to its simplicity, this translator can be assembled in only an hour or two. Circuit boards and components are available, as well as preprogrammed ROMs and complete programming information (see Parts List).

This machine is based on the MOS Technology MCS 6502 microprocessor. This device offers several features which make it attractive for this application: low cost, fast cycle time, on-chip clock oscillator, and single +5 volt power supply. Bus organization is the same as the M6800 and offers simple memory-I/O interface with a minimum of external parts.

The entire system includes a CPU (the microprocessor), a 512 x 8 ROM containing the program, a 128 x 8 RAM, an interrupt timer, and three TTL chips which provide a 1-bit input port, a 1-bit output port, and an interrupt control flip flop. No UART or other parallel to serial converter is needed since this function is provided by the software. The output port feeds the display device directly in serial form. The output data rate is controlled by the interrupt timer, and can be varied to suit the display used.

The complete schematic is shown in Fig. 1. Although it may look intimidating, most of the wiring is just parallel runs from chip to chip. Pins 26 through 33 of Z1 are the data bus over which instructions and data flow between the CPU and the other chips. The address of instructions, memory locations and I/O ports are output on the address bus, pins 9 through 20. The R/W line signals whether data is being read into or written out of the processor. Z5A and Z4B form a 1-bit output port which is connected to data bus 0. Z5B, Z6A and Q2 are used as an input port, driving data onto data bus 7. The 555, Z7, is an interrupt timer. Each time it clocks, the execution of the program is suspended and a new output bit appears at pin 5 of Z4. By varying the rate of the interrupts, the output rate may be set to any desired speed. More detailed information on the 6502 microprocessor is contained in the two excellent manuals available from the manufacturer (see Reference List).

The program is contained in the ROM, Z3. It is an Intel

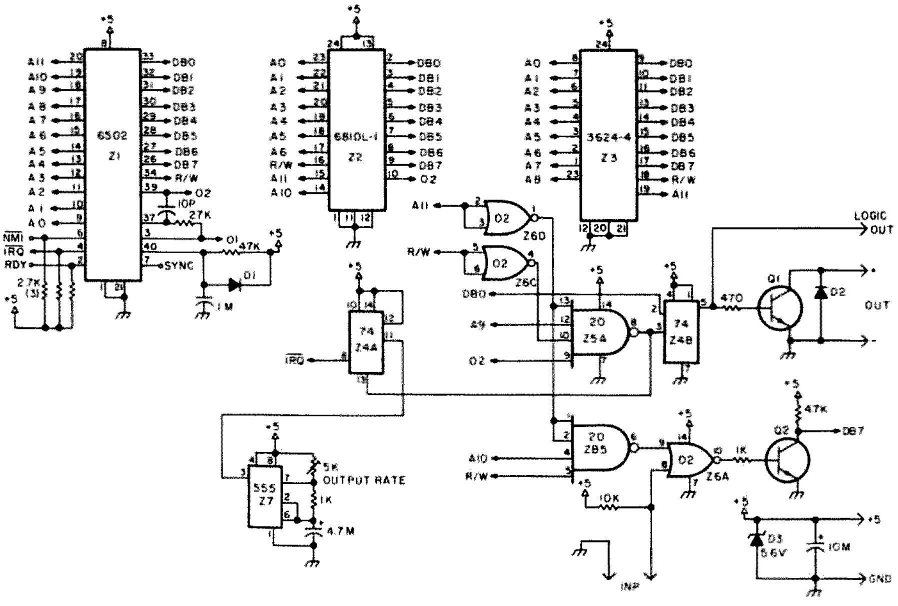

Fig. 1. Schematic.

D-3624, which is a fusible-link, bipolar, tri-state, 512 x 8 PROM. A complete program listing with notes is available, as well as pre-programmed PROMs. Basically, the dot-dash threshold is set equal to half the mark period if the element was a dash, or to twice the period if it was a dot. Thus, the threshold varies between 1/2 and 2/3 of dash time. This provides a tolerance in dot-dash timing, and makes the threshold follow the input code speed. A similar method is used for spaces. Word spacing threshold is initially set for 1-1/2 times the letter space. If more than eight characters are received without a word space, the threshold is decreased. If more than four characters are received with spaces between each, the threshold is increased. This process is iterated until proper spacing is achieved. A counter keeps track of how many characters have been printed in each line. At the first word space following the 64th character, a CR-LF-LTRS sequence is output. This can be easily modified for other printer or display widths, or bypassed entirely by minor changes in programming.

The input is sampled periodically by a software loop, which simultaneously increments a counter. When the input changes state, the elapsed time is represented by the number in the counter. The program processes the timing data, and then begins the timing loop over to wait for the next input change. The output is interrupt driven. Each time a new output bit is due, the timer Z7 clocks Z4A which in turn pulls the $\overline{IRQ}$ line of the CPU low. The microprocessor suspends whatever operation is being executed at the time, and jumps to a subroutine which outputs a new bit via Z4B. It then returns to the main program to resume operations. This procedure requires only 50 to 60 microseconds to complete, so there is no noticeable slowing of the main program execution. Part of the RAM is assigned as a FIFO buffer to accommodate situations such as upper case (FIGS-Char.-LTRS) or end of line (CR-LF-LTRS). In these cases several output characters are output very quickly, and the buffer stores and feeds them out sequentially at the TTY output rate.

Pre-programmed ROM only	$ 42.50
Complete program listing and notes (supplied free with any above)	$ 3.50

Special programming also available – write describing options needed.

Assembly

Construction is simplified by using the available circuit board, which is double sided with plated-through holes. However, wire wrap is also satisfactory. Lead dress is not particularly critical, except pins 39, 37 and 3 of Z1 and to the 10 pF capacitor and the 27k resistor. These are connections for the clock oscillator, and pickup can cause frequency modulation of the clock, which can cause some very strange problems. Reasonably short ground leads should be provided. Z3 in particular draws several hundred milliamps and should have appropriately heavy supply connections.

Be sure to use sockets for all of the ICs. They must be inserted at various points in the checkout procedure. After mounting the sockets, they should be broken in by using the pins of a spare 14 or 16 pin IC. Insert and remove these pins at least once in each receptacle of the sockets, being sure to catch all of the pins of the 24 and 40 pin sockets. This reduces the insertion force required, and lessens the chance of bent pins and broken ICs.

A limited amount of parts substitution can be made. The 6810 must be a -1

version, and the TTL must be low power Shottky to avoid excessive loading. The D-3624 can be either a standard or a -4 version, or a D-3604 can be substituted if eight 10k pull-up resistors are added to the data bus lines. Care should be taken to do the wiring with no mistakes. These components include relatively expensive MOS devices, which are not nearly so forgiving as TTL. Reversed polarity and shorted outputs can be disastrous. NOTE: Do not solder any part of the board without removing Z1 and Z2 first. Do not remove or insert any ICs while power is applied.

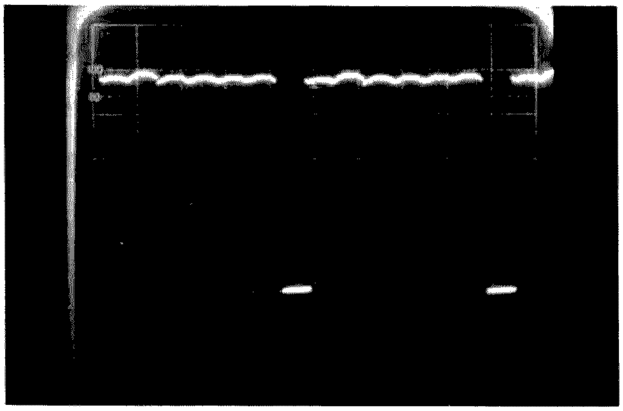

Fig. 6. Input sample pulse after 5 seconds. Z5, pin 6. Vert: 1 volt/div. Horiz: 2 usec/div.

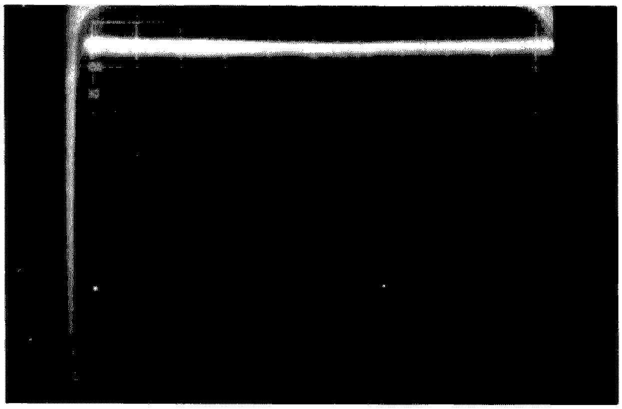

Fig. 7. Interrupt request, $\overline{IRQ}$, Z1, pin 4. Vert: 1 volt/div. Horiz: 2 ms/div.

Testing

A five volt, 400 mA current limited power supply and a 10 MHz scope, preferably dual trace, triggered sweep, are needed for testing. It should be noted that several of the ICs will get quite warm during operation. Z2 and Z3 will be almost too hot to touch after an hour of operation. The others will be slightly warm.

Remove all of the ICs and apply power. Check each socket to verify that +5 volts and ground appear on the correct pins.

Remove power and insert the 6502, Z1. Handle the 6502 by the pins in one hand and support the board on the other while inserting the chip. The conductivity of your body will keep static charges from damaging the MOS circuit. Be careful not to bend any of the pins. For all of the larger ICs it may help to carefully bend the leads on the two sides until they are parallel, to ease entry into the sockets.

Connect the scope to pin 3 of Z1, and apply power. An approximate square wave of about 750 kHz (±30%) should appear (Fig. 3). A similar waveform should appear on pin 39.

Move the scope to pin 7 of Z1. Using a clip lead, momentarily short the anode of D1 to ground. A burst of 1 to 2 microsecond pulses should appear (Fig. 4). The duration of the burst may be from a few milliseconds to continuous. Each pulse signals a new instruction being fetched by the microprocessor. Since there is no ROM to supply instructions, it executes essentially a random sequence, which usually "blows up" and stops executing after a period of time.

Next, insert Z2, the 6810-1, being sure to power off first. Use the same technique as for the 6502. Reapply power, and make the same test as before. The same results should be observed.

Insert the 555, Z7. On pin 3 of Z7 a pulse train will appear (Fig. 5). Set the trim pot for the time period corresponding to the desired output TTY speed from Fig. 10.

Insert the 74LS02, Z6, the 74LS20, Z5, and the D-3624 ROM, Z3. Connect the scope to pin 7 of Z1. You should see a series of 1 microsecond pulses of irregular spacing (Fig. 4). Connect the scope to pin 6 of Z5. Momentarily short the anode of D1 to ground. Immediately following, a 1 microsecond pulse with a repetition rate of approximately 7 milliseconds should appear. This is the input sample rate. After a few

MICROCOMPUTER DICTIONARY AND GUIDE

Charles J. Sippl and David Kidd

This new microcomputer dictionary fills the urgent need for all communications people, computer people, engineers, scientists and industrialists to become quickly familiar with the terminology and nomenclature in a new revolution in computer control capabilities.

Over 8000 definitions and explanations of terms and concepts (704 pages) relating to microprocessors, microcomputers and microcontrollers. There are also separate appendices on: programmable calculators; math and statistics definitions; flowchart symbols and techniques; binary number systems and switching theory; symbol charts and tables; summaries of BASIC FORTRAN and APL. In addition there is a comprehensive electronics/computer abbreviations and acronyms section.

Price: $17.95

CALCULATOR USER'S GUIDE AND DICTIONARY

By Charles J. Sippl

Contains comprehensive sections on (1) what's available in programmable calculators in today's market — including comparisons (2) how to use most units ranging in price from $50 to $3000 (3) a 7000 term dictionary section relating to calculators.

Programmmable calculators are now the keyboard computers for the masses — easily understood and usable by anyone who knows the terminology — students, businessmen, professionals, etc. However, you would be wise to buy a calculator ONLY AFTER READING THIS BOOK! Over 450 pages in all.

Price: $9.95

(Also available from technical book stores and selected electronic distributors)

seconds, it will change to a repetition rate of 8 microseconds (Fig. 6). Each time the system is reset, either by shorting D1 or by reapplying power, this pulse should repeat the same slow, then fast, repetition rate sequence. At this point the CPU is fetching and executing instructions properly.

Insert Z4, the 74LS74. Connect the scope to Z1, pin 4. A negative-going pulse of approximately 50 microseconds duration should appear, with a repetition rate equal to the period set by the trim pot earlier (Fig. 7). Careful examination of this pulse will show some jitter in its width (Fig. 8). This amount should be less than 1% of the pulse to pulse spacing.

Connect a key from the input to ground. (If a keyer is used, be sure it is set up to switch positive voltages to ground.) Put the scope on the logic output pin. Set the timebase to 20 milliseconds/division. Send CQspaceCQspaceCQspace . . . After a few characters, the beginning of each character should trigger a series of pulses (Fig. 9), with the series following the space being twice as long (because it is Character-Space sequentially). These series of pulses are the serial TTY output.

Connect the TTY machine or display as shown in Fig. 11. Be sure to watch polarity and grounds. Fig. 11 also shows the configuration for TTL compatible outputs. Now the machine should print the correct translation of the input code. Word spacing will take three or four words to settle down. An automatic CR-LF-LTRS sequence will be output after the first word space following the 64th character of each line. Unless an unusually long word (such as microprocessor) is sent, this will prevent breaking up of words.

Speed (wpm)	Z7 Period
60	22.22 ms
66	20.20 ms
75	17.78 ms
100	13.33 ms

Fig. 10. Z7 timing period for TTY output speeds. One new bit is output for each pulse for Z7. Higher speeds can be obtained by changing the timing components.

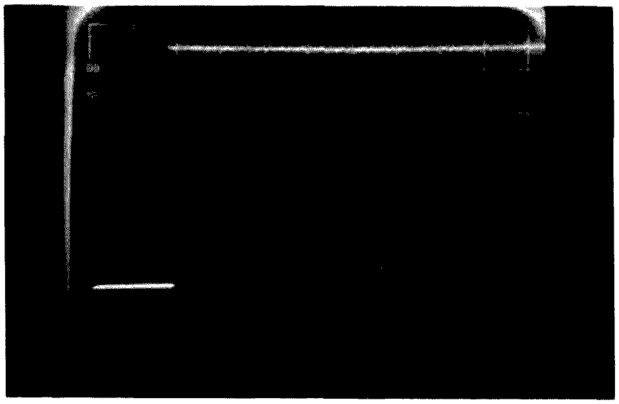

Fig. 8. Interrupt request, $\overline{IRQ}$, Z1, pin 4. Vert: 1 volt/div. Horiz: 20 usec/div.

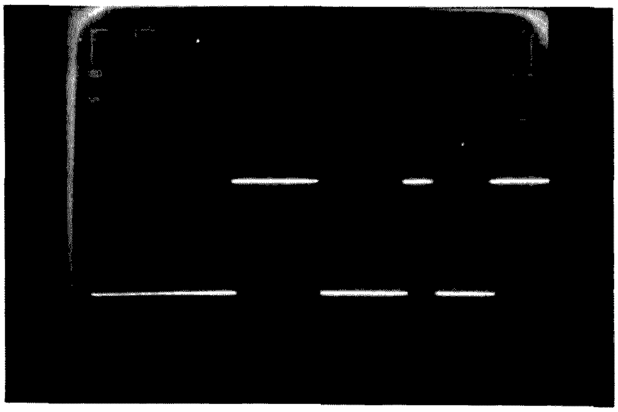

Fig. 9. Logic output. Vert: 1 volt/div. Horiz: 20 ms/div. This is the serial TTY output (set for 100 wpm).

The printer will normally be one character behind. This is because it is still measuring the space until the next mark comes along. Each character will be output as soon as the following one starts.

There is a built-in buffer of approximately 40 characters which is designed to accommodate extra characters like FIGS, LTRS, CR, LF, etc. It will also allow input code speed to exceed TTY output speed for a brief time. The speed range is limited on the high end by the TTY machine speed used. For a 60 wpm printer, it will limit at about 50 wpm code speed, and for a 100 wpm printer, about 65 wpm code speed. A programming change to increase the sample rate used at the input will allow a higher upper limit, with a corresponding increase of the minimum from the normal 5 wpm.

There are two things to check in case of difficulty. First, be sure you are not running your letters together. It is a natural tendency to try to send as fast as possible to test this type of system, and this usually results in running letters together. Remember, the machine is relatively dumb, and doesn't know that – . . . . is really "the" and not "6" because you don't say "6 real thing."

The delayed audio feedback caused by the printing delay can also raise havoc with your timing. A pair of headphones or a silent printer is the cure.

The other thing to check is that the output speed is set carefully to match the TTY machine speed (within 1%). A clue to mismatch here is consistent errors such as extra Ts after, or instead of, spaces, or CR instead of spaces, etc. Also check to be sure the loop supply being used is compatible with the TTY machine. Newer models are fairly tolerant of open circuit voltage and exact current, but older machines are not. Substituting a keyboard for the translator is a quick way to check this.

Conclusion

Your Morse code translator will now operate from a key or keyer. I will be happy to attempt to assist in case of difficulty, but please send an SASE. ■

Number Systems

-- a brief history

Have you ever wondered about the term "binary number" that you have seen in electronics magazines? Since we already have a perfectly good decimal number system, why complicate things with another? If you have a few minutes, here is your chance to learn more about number systems than you ever wanted to know.

One of the most important achievements in the development of science has undoubtedly been the invention of our decimal number system. Counting in units of ten must certainly be due to the fact that man has ten fingers. In some cases, some people have counted in units of five or twenty, which correspond to the use of one hand or of both hands and both feet.

The main use of numbers in early times was for simple counting and record keeping. The numeration methods were designed chiefly for those purposes. With the development of trade and the sciences, the numeration became more and more inadequate. It took a long time before an adequate number system was devised. The Greeks and the Romans did not succeed in this endeavor even though they achieved a rather high development in science. Just imagine performing simple arithmetic with Roman numerals, like dividing MMDXLVI by CCIX using Roman numerals only. About six hundred years ago any simple operations like multiplication and division of large numbers required the services of an expert.

The Hindus and the Arabs are credited with the concept of positional value and the use of the zero, which are explained as follows. Consider the number 74638. We understand this to mean 7 x 10,000 + 4 x 1,000 + 6 x 100 + 3 x 10 + 8 x 1. In the following numbers, the 4 has different values depending on its position: 42,000, 240, 324. In the first number 4 is equal to 40,000, in the second its value is 40 and in the last just 4. Without a 0 to place in some of the positions, how would you write three hundred and six if every position had to have a number? Use of the concept of zero enables us to write 306.

The positional values of the base ten number system are as follows:

$10^3\ 10^2\ 10^1\ 10^0.\ 10^{-1}\ 10^{-2}\ 10^{-3}$

You will note that in each case the value of the position is the radix (10) raised to some power. It is necessary to go to the right of the radix point (decimal point) in order to express fractional numbers.

The general expression for a number is then:

$$N = a_1(r)^{n-2} + a_2(r)^{n-3} + a_3(r)^{n-4} + a_4(r)^{n-5}$$

In the above expression r is the radix or number base and the a values are the position numbers. In order to have a base ten number system that will translate most practical numbers we would have to make n = 5. Using the arbitrary number 2307.602 as an example, and making n = 5, we derive:

$$2(10^3) + 3(10^2) + 0(10^1) + 7(10^0) + 6(10^{-1}) + 0(10^{-2}) + 2(10^{-3})$$

Note that any number raised to the zero power is equal to one (i.e., $10^0 = 1$).

Now we can calculate the positional values for the binary (base 2) number system. They are as follows:

$2^0 = 1$
$2^1 = 2$
$2^2 = 4$
$2^3 = 8$
$2^4 = 16$
$2^5 = 32$
$2^6 = 64$
$2^7 = 128$
$2^8 = 256$
$2^9 = 512$
$2^{10} = 1024$

$2^{-1} = .5$
$2^{-2} = .25$
$2^{-3} = .125$
$2^{-4} = .0625$
$2^{-5} = .03125$
$2^{-6} = .015625$
$2^{-7} = .0078125$
$2^{-8} = .00390625$
$2^{-9} = .001953125$
$2^{-10} = .0009765625$

We now have the conversion factors necessary to convert a binary number to a decimal number.

Let's consider the base 2 number 0011100.0 and calculate its decimal equivalent.

0 x 1 = 0
0 x 2 = 0
1 x 4 = 4
1 x 8 = 8
1 x 16 = 16
0 x 32 = 0
0 x 64 = 0

28 (base 10) = 0011100.0 (base 2)

It may not have been apparent from the preceding, but the fact is that binary numbers are made up of 1s and 0s only. If we were to design an electronic computer or calculator to use the decimal number system, we would find that the decimal number system was capable of the high speeds that are necessary – but it would be very difficult to provide ten stable states so that the computer could handle the decimal numbers. Fortunately, any number can be represented in the binary number system, so computers are designed to use it. They might also use the base 8 or base 16 number systems,

since these have similar properties.

Electronic circuits have been devised that will add, subtract, multiply, and divide in the binary number system. If you are interested in these processes you could consult any text on computer design. Several are listed in the references at the end of this article.

Just to stimulate your interest in the binary number system, let's try working a problem. First we need to know that in the binary system 1 + 1 = 0 plus a carry. The carry is into the next position (or 2^1) so that properly 1 + 1 = 10. This happens in the decimal system also; for example, 9 + 9 = 8 plus a carry into the 10^1 column, so that 9 + 9 = 18. Now let's try out your new understanding of number systems on this little problem. Calculate the first five positional values to the left of the radix point in the base 8 number system (remember, 8^0 + 1). Then calculate the decimal equivalent of the octal number 40. The answers follow the references.

Now that you are up on number systems, you don't have to skip over the articles that refer to the binary number system. Things like electronic keyers use them, especially if there is a memory involved. A lot of the integrated circuits manipulate them also. Have fun! ■

DON'T LET US DOWN

Where are the MARCH PROPAGATION CHARTS? I just received my April issue of *73 Magazine*, and no chart for March. Of course there was the April Propagation Chart, but this doesn't help for March.

I started taking *73 Magazine* when I found they had Propagation Charts. Thanks, for letting me bring this to your attention. Please don't let us down again.

Ivan S. Miller W5HFU
Oklahoma City OK

Sorry — it won't happen again. Due to a change (acceleration) of our production schedule, we were forced to miss a month of John Nelson's fearless (and unbelievably accurate) forecasts. — Ed.

ARE YOU SURE? (NO)

Re your article in the March '76 issue of *73 Magazine*, page 44.

Are you sure this article should have been published in the March issue? (Does it not belong in an April 1st issue?)

The diameter of the disc has no bearing on wind speed; it would give one count per revolution whether the disc was 1/8" or 1 yard in diameter. The rpm would only be determined by the length of the arms — the shape of the cups minus friction of the *bearings*.

A chip of mirror glued to the shaft to reflect the light from the LED to photo cell would work just as well.

Until reading this article I had thought *73 Magazine* was a serious ham-oriented magazine — not just for laughs. I believe this space should have been occupied by a more realistic theory.

Ulmer S. Anderson W7MHY
Hadlock WA

I published an article on a frequency synthesizer in the Sept. '75 and Oct. '75 issues of *73*, and I am sorry to say that I have only now discovered an error in it. The tuning diodes used in the oscillators should be type MV1404, not MV1401 as listed. The MV1401 diodes have too high a capacitance (nom. 550 pF as opposed to 120 pF for the MV1404), and if they are used the oscillators will only operate with control voltages above 6 volts.

I hope you will publish the above in your letters section; it will save anybody trying to build the synthesizer a great deal of frustration.

Noel Calvin
Berkeley CA

I just finished the April issue of *73* and must comment on the fine articles in this great issue.

Nat Wadsworth's article "Computers are Ridiculously Simple!" was very informative and nicely written; from what I learned it seems to me that Fig. 7, picturing binary number 10101010, should be decimal value 170, not 160 as stated.

No doubt you will have many other letters correcting this. Hi. Hi.

I also intend to give your staff more work on the Reader's Service page this month, as you request.

Keep up the good work on a fine magazine; can we see more articles on ATV and SSTV in upcoming issues?

Charlie McBride VE3GYT
Grimsby ONT

I made a mistake on my Touchtone Decoder article (April, 76) in regards to the parts availability from CONTACT. The price quoted was intended to be for the printed circuit board alone. Inasmuch as there is no way CONTACT can supply the relay and board for the price stated, checks are being returned with my regrets for the error. Incidentally, the wired and tested version is going for $29.95.

William J. Hosking W7JSW
Scottsdale AZ

I've noticed an error in the April 1976 issue of *73*, page 63. The article is entitled "Inexpensive HF-VHF Frequency Standard."

Please note the following correction to the schematic shown. *Pins 2, 3, 6, 7 on each of the 7490 decode dividers must be grounded.* Other than this all looks fine. Thanks.

Gene Hinkle WA5KPG
Austin TX

UPSET

I was extremely upset over the first four lines of an article in your February 76 issue by Larry Kahaner W82NEL (*see page 136*). He said, "While in my neighbor's house one day explaining how I can phone patch her brother in Germany, etc." Third party traffic into Germany is verboten and it is fellows like that that are causing the problems that we now have concerning reciprocal operating privileges here. The German Oberpostdirektion is seriously considering withdrawing privileges for armed service personnel here, i.e., all DA calls. It seems that U.S. amateurs have the mistaken idea that an unlicensed person in the U.S. can talk to a licensed person here if they are physically at the U.S. licensed station. This is not true and that is causing the problem. Licensed operators here can only talk to licensed operators there. I cannot talk to my mother, for example, even if she goes over to my sister's home. My sister is licensed and I can talk to her, but no one else. Also, there is a kicker — if my sister were a Novice, I would not be able to talk to her on YOUR station unless I talk on the U.S. Novice band (which I can do) and she answers me CW, *and* your station is complying with Novice rules with respect to power, crystal controlled, etc. I would not be able to talk to a Technician at all unless it was on 2m.

Hugh G. Vandegrift

DOWN OUR THROATS?

Enjoyed seeing you at Vegas. I thought you might like to know that there is 220 activity now in Phoenix. Just a few on 223.5 simplex for now, but there is talk of a repeater or two in the near future. More about that later.

The Summer Hamfest sponsored by A.R.C.A. will be on July 30-31 and August 1, this summer, at Ft. Tuthill in Flagstaff AZ.

I like your new format in *73*, but I have one large gripe. Why are you shoving all this computer/microprocessor stuff down our throats? I buy *73* because I want to read about ham radio type activities, otherwise I would buy BYTE.

Bill Sargent WA7UJH
Phoenix AZ

Hi Bill, good to hear from you . . . re computers, the microcomputer is the most fantastic component for electronic systems yet invented . . . this means you will be using it in almost every piece of ham gear before long. Bill, you can remember the fuss when I started pushing FM and repeaters . . . older timers will remember the resistance I had to sideband and before that to RTTY . . . I'm used to fighting upstream on new ideas. Remember the terrible trouble I had getting hams

ASCII/Baudot with a PROM

-- for ribbonless RTTY or computers

Video displays are becoming increasingly popular in RTTY. In addition to eliminating the noise of mechanical printers (appreciated by the XYL), there is no mechanical maintenance or paper/ribbon changing. The video user has the ability to rapidly change baud rates for use in copying commercial stations and to use the video unit together with microprocessors.

Commercial kits start at $395 and up. This discourages many RTTY enthusiasts. Fortunately, Southwest Technical Products has a video display unit for $190.50 with power supply called the CT-1024[1]. It requires the user to accomplish his own Baudot to ASCII code conversion, which is the subject of this article. The result will be very close to the commercial units available with 3 exceptions:

1. *Page Size.*

HAL RVD-1005 – Has 40 characters/line, 25 lines for a total of 1,000 characters ($575); Leland – Also has 40 characters/line, 25 lines ($395 in kit form); CT-1024 – Has 32 characters/line, 16 lines for a total of 512 characters. Another 512 are stored for a 2 page memory.

2. *Scrolling.*

Both the Leland and HAL units scroll up the page. That is, each new line appears on the bottom and pushes the remaining lines up one. The SWTP CT-1024, on the other hand, wraps continuously around the screen. When it gets to the bottom, it starts over again at the top of the screen. The blinking cursor identifies the current position.

3. *Treatment of words at end of line.*

Both the HAL and Leland units start a new line somewhat prior to the actual end of the line on a space character, so as to not separate a word in the middle. This is not available on the CR-1024. It would be relatively easy to add with some counter ICs if needed.

Fig. 1. Overview – basic RTTY use only.

Basic Display Overview

Fig. 1 shows the functional flow of data from the RTTY terminal unit to the video display. At this point, you have the equivalent capability of the commercial displays previously discussed.

Fig. 2 shows three ways of getting from your present RTTY setup to the TTL logic level signals required by the BAC-2. Note that the output of the ST-5/ST-6 terminal units is the same as the RS-232C commercial data standard so that modem out-

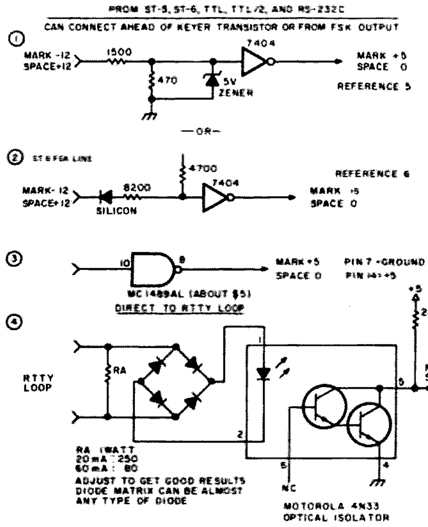

Fig. 2. Connection from RTTY loop to BAC-2.

puts could be treated the same way. Two of the circuits are described further in the references. The current loop interface can be used with any terminal unit and may be of interest to non-RTTY microprocessor users who want to use Baudot teletype equipment. The current loop interface is totally isolated from the loop.

Fig. 3A details the heart of the unit – the Baudot to ASCII converter – dubbed the BAC-2 (someone has probably designated a BAC-1!). The circuit provides:

1. Serial to parallel conversion of incoming Baudot signals using a UART and multiple speed clock for various baud rates.
2. Conversion to ASCII using standard 8223 PROMs (programmable read only memories).
3. Letters/figures case shifting from the 8223s to U4 wired as a cross coupled flip flop.

Fig. 4 details the connection of the BAC-2 basic unit to the SWTP CT-1024 terminal unit. Keyboard connections are specified – the user can also go in via the pins on the back of the unit. With parallel data, keep the lines between the BAC-2 and CT-1024 *extremely* short. Over 18 inches and ringing is likely to occur. The BAC-2 might be mounted right on the CT-1024 as shown in the picture.

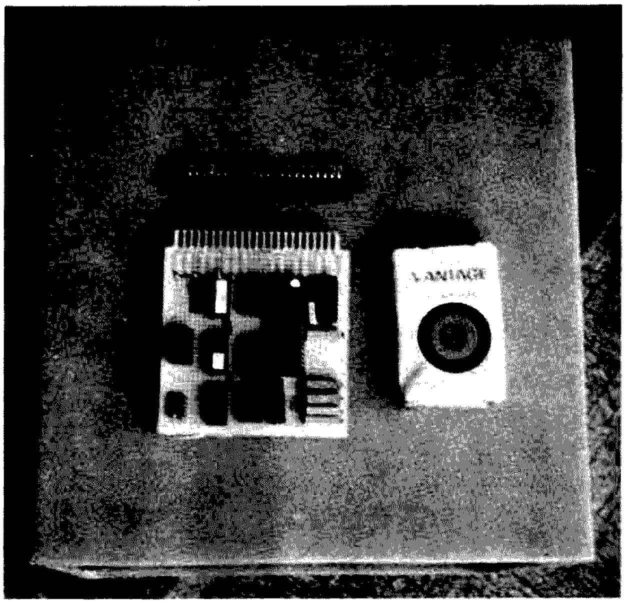
Optional Circuits

Up to this point I have described using the BAC-2 primarily for RTTY copying. This will undoubtedly serve the needs of many readers. However, with microprocessors becoming more available and inexpensive every day, you might want to plan ahead now. I have a microprocessor using the Motorola 6800 CPU that provides all of the functions of RTTY Selcal, CW and RTTY ID, FIFO/UT-4 buffer storage, automatic transmitter control, ASCII-Baudot code conversion, and numerous other RTTY goodies. Use of a microprocessor is very easy and far less complex than wiring up a lot of discrete components for functions. Moreover, the functions can be changed much more quickly and easily by just changing the program.

If your future plans call for a microprocessor, you should plan now to get into serial mode rather than parallel mode for transferring data. Parallel mode has two disadvantages from my point of view:

1. Line lengths and interfacing techniques get tricky as you add devices and circuits. Serial start-stop, on the other hand, is very forgiving and insensitive to glitches on the leading and trailing edges of pulses.
2. It is a snap to switch electronically between several input and output devices in serial mode. With parallel data either data selectors (such as the 74157) or tri-state buffers are needed. Further, the timing sequences for strobe pulses to indicate a character ready get pretty tricky with tri-state devices. Timing chips and extra circuitry will quickly cost far more in dollars and time than a couple of UARTs.

Fig. 5 shows a functional overview using the BAC-2 in a RTTY system with serial data flows. All data is flowing in TTL logic format (Mark = +5 V, Space = 0 V). Other units you may have can be readily added by converting them from/to serial mode. While the NAND and inverter gates don't really belong in a functional diagram, they help show how the pieces are integrated. The only things needed to be added for complete versatility are some switches to select/control the serial data flows as needed for use with the microprocessor. They can be omitted at this point for display use only. Note that the 8th or parity bit is ignored in all ASCII circuits. The steps through Fig. 3A are the same as the basic unit discussed previously. In Fig. 3B a PISO (Parallel to Serial Output) circuit is shown. The NE555 timer should be set to 110 Hz for 110 baud or 300 Hz for 300 baud use. It is simple and reliable and is discussed in depth in the *TTL Cookbook*[2]. Note some deviations from the *TTL Cookbook* diagram – the circuit as shown in the book does not work. Probably some minor typos in printing of the book. The same circuit is shown again in the path from the ASCII keyboard (if used) to the serial data flow. Use of an optional circuit between the keyboard and PISO to do things like repeat key, counting characters, and so forth may be desirable and is discussed in a past issue of *73*[3].



The BAC-2 and PISO Optional Circuit Board. A pack of cigarettes is included to show size and is not required for successful operation.

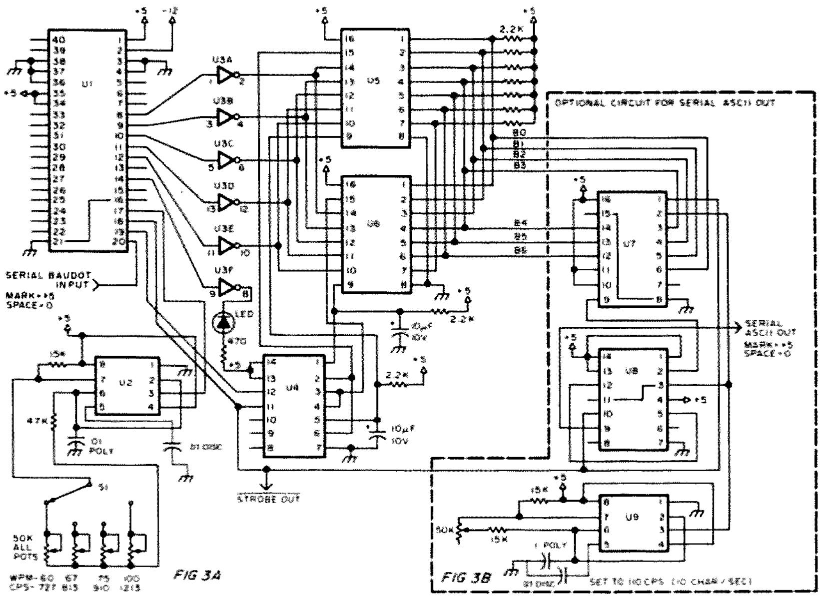


Fig. 3. Baudot to ASCII converter. U1: UART (see text). U2: NE555 timer. U3: 7404 6-inverter. U4: 7400 4-NAND. U5, U6: 8223 PROM. U7: 74165 PISO register. U8: 7474 flip flop. U9: NE555 timer. All resistors: ¼ W 20%. S1: single pole, 4 position rotary. LED: any LED.

Use of two gates provides the mixing of ASCII signals from the keyboard, BAC-2, and/or microprocessor. If not using a micro at this time, simply leave the connections open and tie the ASCII from the microprocessor to +5 V for now.

Fig. 6 shows a serial to parallel (SIPO) converter to front end the CT-1024 terminal. Not much to hooking it up. SWTP also has a CT-S kit available for $39.95. It involves a lot of conversions from/to the commercial RS-232C standard, which is nice if you use it. The SIPO circuit can be built for less than $10 depending on where you get the UART.

We use Fig. 4 again to interface from the SIPO to the CT-1024 terminal. Same leads and terminology — just a different source.

Fig. 7 is optional and converts the serial data from TTL to the commercial RS-232 standard for use with an "outside world" terminal such as commercial computer video displays, printers, or 33 teletypes with RS-232 conversion built into the TTY.

At this point, you are probably wondering where the ASCII to Baudot circuit is. We have everything flowing everywhere but back to the teletype. The answer is there isn't any! The microprocessor provides the tool for the code conversion and the FIFO type buffering of data. If you don't plan on a micro, a circuit to convert from ASCII to Baudot can be constructed and was described in a recent *73* issue[4]. The micro also provides for CW/RTTY ID, "Here is" Key, and other goodies to the RTTY system.

Construction of the BAC-2

The circuit was constructed using wire wrap methods. Not only is it inexpensive, relatively fun (you can overlap wrapping and watching TV at the same time with the family), but also totally flexible as far as experimenting and making changes. Requirements are a wire wrap tool[7], some wire (#30 Kynar — $10 for 1,000 feet usually, or available prestripped), a wire stripper (filing a notch in a pair of needle nose pliers with cutter is good), wire wrap sockets, and a board. Radio Shack has

a new board (276-152) for $2.99 which provides space for IC sockets and a dual 22 pin edge connector. The mating connector (276-1551) is also $2.99. Watch out for some boards that have holes every .200 inches rather than .100 inches per the catalog specs. Somehow these crept into stock in a few stores and should be avoided. The board includes the PISO circuit of Fig. 3B. You may want to consider crystal control of the baud rates using circuits that have appeared from time to time in the *RTTY Journal* or *73 Magazine*, if a counter is not available. I have had no trouble with the NE555 timers. Of interest in Fig. 3A is an LED indicator connected to pin 14 of the UART. If it flashes, the incoming data has no valid stop bit. This is super for copying commercial stations with varying shifts, baud rates, and upright/upside down shifts. Just experiment with the controls until the bad stop LED goes out.

Readers who have built a UT-2/UT-4, or other equipment incorporating a UART, can skip U-1 and U-2 in the diagram and connect directly to the code conversion circuits in parallel form. Likewise, the UART can be used to up speed convert at no extra charge by wiring up the transmit side of the UART to convert all Baudot to, say 100 wpm.[6] The transmit side of the UART cannot be used for the serial ASCII output in Fig. 3B due to the limitation that it be used with either 5 or 8 bit code on both sides (you can't split it). When a valid character has been received by the UART, the data received line (pin 19) goes high. It is inverted and connected to the data received reset (pin 18) to reset the UART. The data is available prior to the data received line going high and stays so until the next character comes along allowing plenty of time for the 8223 PROMs to convert the code. The reset (pin 18) gives us a strobe line that is negative going to trigger the PISO circuit or the CT-1024 terminal depending on hookup.

The received data (pins 12-8) of the UART are buffered by 7404 hex inverters to protect the UART, provide the drive for more than one code converter chip, and allow use elsewhere.

Code conversion is accomplished by two 8223 PROMs. These are available from a variety of sources. A self-programming technique was described as a part of another circuit in *73*.[8] The author of that article also mentions references for programming. Fig. 8 shows the bits to be programmed (blown to 1) on the 8223s. These are the Mark-Sense cards used by Hamilton-Avnet, a major wholesale distributor of ICs. Hamilton charges $8.95 each to provide an 82S23 (newer version of the 8223) already programmed ($6.45 + $2.50 programming) per the specs of Fig. 8 if you have prepared the card. The cards shown are for unshift on space — bit 7 is used to select the other chip when going from letters to figures. Terminology for the two chips is described in Fig. 8 for communication purposes together with the distinction between having unshift on space or not. If you want the option of switching between unshift on space or not, you might add another 8223 with a switch to the enable line (pin 15), or add some gates to select the

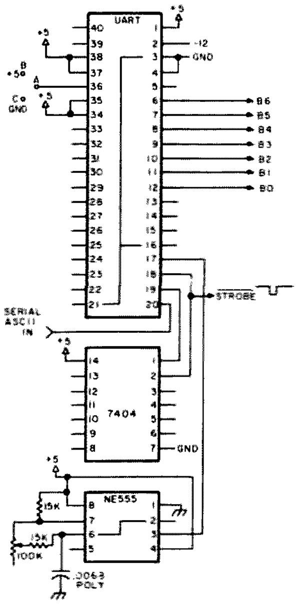

Fig. 6. Serial in/parallel out (SIPO) for ASCII code. Jumpers: A — B, 2 stop bits; A — C, 1 stop bit. Adjust for 16x baud rate: 110 baud = 1760 Hz; 300 baud = 4800 Hz.

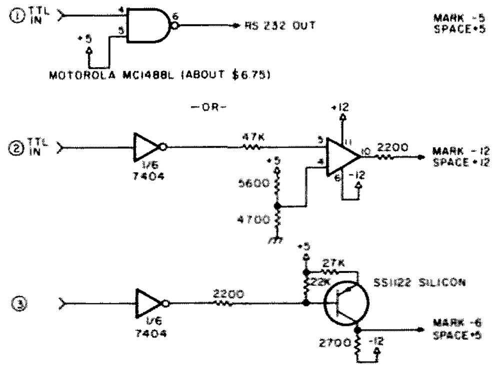

Fig. 7. TTL to RS232-C conversion.

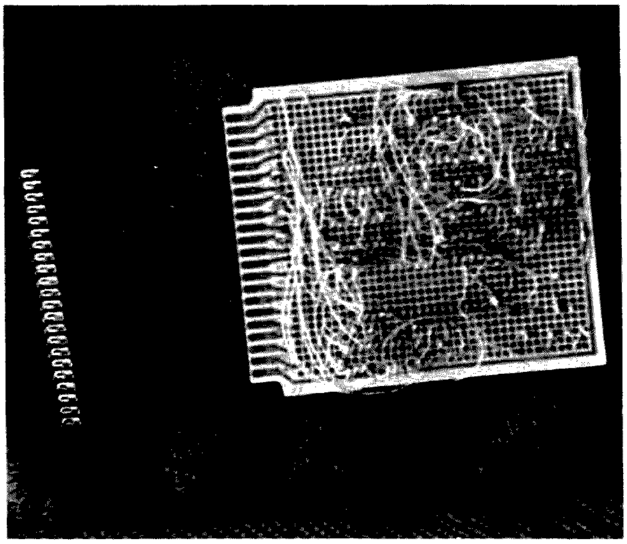

Flip side of BAC-2 board. The wire for wire wrapping is a very pale yellow and doesn't show very well.

character yourself. Note that the Baudot control functions, Letters, Figs and Blank, are all translated to the ASCII Rubout (all 1s) character to be ignored by either your microprocessor or video display. The two 10 uF capacitors prevent the flip flop for letters/figures from triggering as the 8223s change state.

The CT-1024 Display Unit Construction

The SWTP display unit is available in kit form for $190.50.[1] Boards only are also available for $47.50. The ICs and discrete components can be purchased from *73* advertisers for $50-70 in total. Readers with a well-endowed junk box might want to go the board route to save money. Caution: The boards are very complex and built to excellent and exacting standards by SWTP. I would not recommend attempting to make them yourself or to purchase them from anyone other than SWTP. *Radio Electronics*[9] magazine carried a series of articles on the CT-1024 if you want to read more prior to making a decision (the TV Typewriter II in the series). I don't recommend the TV Typewriter I (Sept. 73 *RE*), as some additional interfacing is needed for it to properly handle the line feed, carriage return, no display of rubouts, scrolling, clear, etc. The TVT I is tough to use either with a micro or RTTY without extensive rework.

A feature not described by SWTP is to tie pin 3 to 7 of the cursor socket (J3). This causes the CT-1024 to clear the next line upon receipt of a CR/LF combination. Without this, it provides a very confusing display. It automatically starts a new line and clears it when the end of a prior line is reached (non-overline) when wired this way.

Assuming that you have built up the CT-1024 in one form or another, the next step is to interface it with a TV set. The CT-1024 instructions provide an interface to a Motorola TV. Lancaster[10] discusses interfacing video signals to TV sets in depth in a recent BYTE article, and will have this available in a "TV Typewriter Cookbook" shortly. You should be able to test the CT-1024 by grounding the data line that you want to be a zero and then grounding the strobe line to see that it is working. An ASCII keyboard could also be attached to check it out.

The SIPO (Serial In/Parallel Out) Circuit

The circuit in Fig. 6 can be readily constructed on perfboard or the same Radio Shack boards discussed previously. Set the NE555 timer

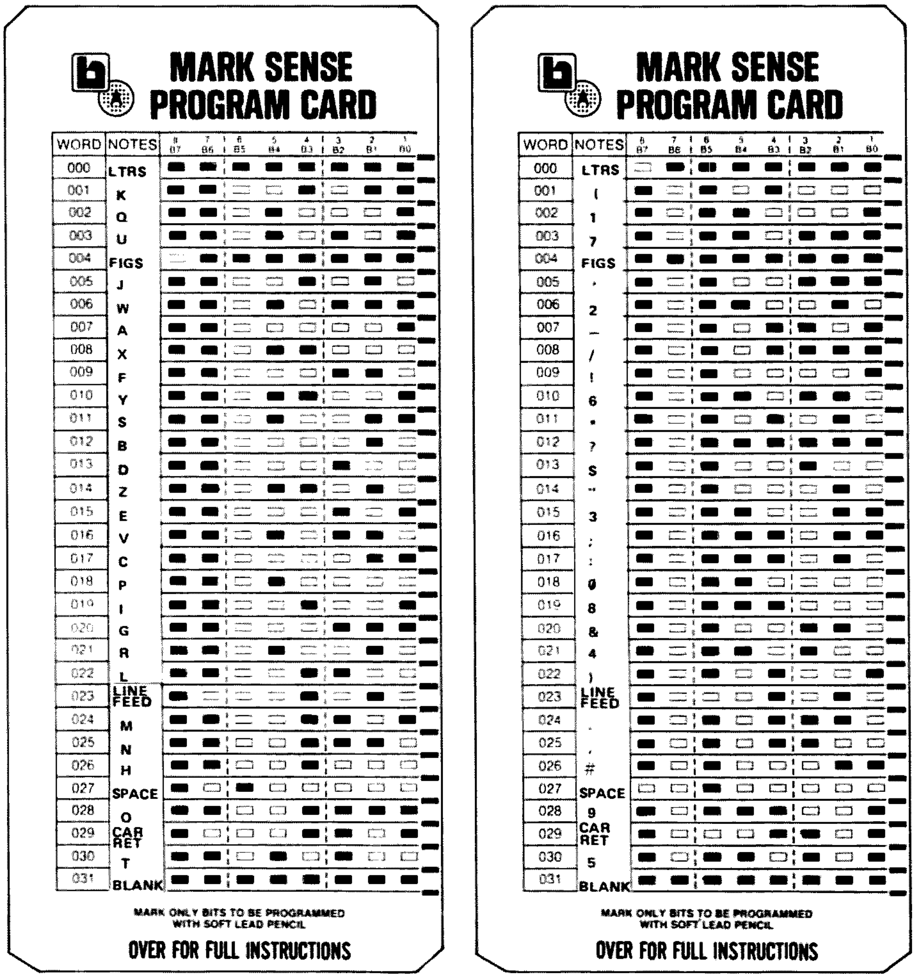

*Fig. 8. 8223 read only memory coding. Bell prints as *. Blacken B7 (first box) to block unshift or space.*

rate to 16x the baud rate; i.e., for 110 baud/10 characters per second, 1760 Hz would apply. Jumper A to B for 2 stop bits (110 baud), and A to C (300 baud +) for 1 stop bit as necessary.

Conversion to RS-232C Standard Data Logic

Fig. 7 shows possible ways to convert from TTL to RS-232C logic. Either results in pretty much the same thing. The trade-off is what power you have available versus using discrete components.

UART Considerations

The UARTs specified in the various circuits are the "standard" variety. Makers and models are as follows:

1. Texas Instruments – TMS6011.
2. General Instrument – AY-5-1013 or AY-5-1014. The 1014 is nice in that no −12 V is needed – pin 2 is left unconnected.
3. Western Digital – TR1602B.

These are readily available from *73* advertisers and other sources.

Summary

I have discussed various ways of setting up the conversion from Baudot to ASCII and the video display. Hopefully, you will be able to select the options that you want. The Baudot to ASCII circuit (BAC-2) in and of itself may be useful for working with a microprocessor in that the program to convert back again can be readily loaded from 5 level paper tape using Baudot equipment. Once loaded, the conversion back can be done via the program. This enables SWTP M6800 microcomputer system users to use 5 level equipment and avoid going to ASCII equipment. I do not have a source for printed circuit boards – let *73* advertisers know if you need them and perhaps someone will make them up. ■

I/O EDITORIAL

from page 81

Of course it is always possible that pressure on Congress will get so great that the postal monopoly will be broken. Right now it is a federal crime to compete with the post office. The mail could be carried at a good profit by private industry, if it were permitted. Industry could get the postal system back on its feet if permitted by the bureaucracy and the postal unions, something that doesn't seem even remotely likely.

Last year the post office rang up an $825 million deficit and it is expected to be almost double that by the June 30th end of the current fiscal year.

Every time I pause to think about our having to send a piece of paper from New Hampshire to California in order to communicate a message it makes me angry. It is ridiculous in these times. Letters can be sent by facsimile, by teletype, or some computer code and sent via wire, satellite or microwave. Western Union screwed up . . . if they had been looking ahead they would have gotten aboard some really inexpensive message system. Ma Bell (you probably noticed the page 3 mention, in May, of the wind up of her suit against *73* . . . *73* admitted no fault) could have worked up a good system using Bell wires and communications systems.

The soon to arrive inexpensive small office and home computer surely will blow off the lid. I'm still talking with the salesmen for the large computer firms and they apparently are still completely unaware of the revolution that is brewing in small computer systems. They say, oh yes, the microcomputer will cut the cost of the CPU (central processing unit), but there is no way that the cost of the peripherals is going to come down substantially . . . and after all, the cost of the CPU is not very significant for most systems, so therefore the cost of computer systems will stay up there in the $50,000 plus range for a long, long time.

Baloney.

Please don't tell the ivory tower boys about what is happening . . . about what is coming. We don't need IBM in there . . . or DEC. Let them keep working on their $100,000 systems and selling them the way they are right now. This will make it possible for a whole new bunch of companies to grow into the new field rather than have the old ones just keep getting bigger and bigger.

Let's take a look at the peripherals. One thing we need a lot of with any system are the CRTs . . . call them video typewriters or television typewriters (TVTs) . . . these are the primary input/output devices we will be using. Today you can buy a real dumb TVT for maybe $1500. The more sophisticated ones run double to triple that. I envision a CRT with a keyboard and a lot of smarts selling for under $200. It will have a microcomputer chip in it and be able to do a lot . . . play games . . . let you type letters and edit them . . . store a lot of form letters . . . do bookkeeping . . . keep all sorts of files . . . and a whole lot of things we haven't thought of yet. It will need some sort of file cabinet memory storage . . . probably not invented yet.

There are some storage devices in the works. Right now it costs about $5000 for a floppy disk system . . . that should drop to about $1500 in a few weeks when Diablo's new dual $1000 floppy drive is released. Others are in the works for $600. Somewhat slower tape systems will be able to hold enormous amounts of data . . . and at prices which will make DEC salesmen shake their heads in disbelief.

Speaking of Bell . . . the phone company got itself into the Blue Box situation because some engineers ignored a lot of the savvy of other engineers who warned them that using the same lines for signaling and customers was a bum deal. In the long run it is costing Bell heavily for trying to use one pair for everything. A relatively few signaling lines could switch vast numbers of communications lines . . . and there would be no problem with customers sending signals to bollix the charge meters.

Funny thing about the series we published on the phone circuits . . . until Bell made a big deal about it no one seemed to pay any attention. Bell could hardly have gone more out of its way to make sure that the article was noticed . . . coast-to-coast publicity on the radio, television and in the press! They sure brought a load of inquiries on *73* for copies of the magazine or the articles . . . we probably could have sold several thousand copies of the material if we'd been interested in helping people to defeat the phone system . . . but we just turned down all the requests.

Now, after paying several thousand dollars in legal fees, I don't think I should have been quite as solicitous of Bell's interests. On the other hand, after reading the underground telephone newsletter, I am convinced that Bell is able to locate Blue Boxes fairly fast these days and the circuits, even if people discovered how to use them . . . which was not explained in the articles . . . you had to know that or read it elsewhere . . . they would have gotten into trouble.

The recent arrival of programmable pocket calculators at more affordable prices offers the serious ham a new tool to improve his DX through proper antenna orientation. It also gives him a very good excuse for buying one of those very interesting new calculators that can be taught to perform in seconds what would otherwise be a rather messy calculation. After all, with the investment already made in a two gallon linear, hundred foot tower, and stacked yagis, it would be a shame not to get through the pileup because the antenna was pointed wrong. So will buying a programmable calculator fix this? It's not quite that easy, but even if you know nothing of computer programming and aren't too good in math, you can program this very useful computation.

Aim Your Beam Right

-- with a programmable calculator

Before proceeding further, some mention should be made of current practices among amateurs. All too often a ham utilizes great circle maps or azimuth information determined for a location considerably different from that of his QTH. This error, together with the tolerances encountered in orientation toward true north, mechanical drive backlash, and direction indication, can result in an appreciable loss of signal strength in the desired direction. The worst part is that the better the antenna, the less tolerant it is of error in direction.

The problem of finding true north, orienting the antenna, zeroing out the indicator and backlash error, and using maps and/or formulas for determining direction are all covered in various ham publications. Assuming proper attention to all the mechanical requirements yields acceptable accuracy, determination of the proper direction is the next concern. Great circle maps are good if your QTH happens to be near the map center. Otherwise, you are left with the pin, string, and globe approach. There are spherical trigonometry formulas one can use, but nobody in his right mind would recommend them. If one is reasonably careful in performing the calculations, a "correct" angle can be determined. Whether the angle is positive or negative, is referenced to north or south, or is the long or short path, is much in question. After much frustration, I set about to find a means of determining the azimuth from my QTH to any point on the earth without having to perform any calculations, map perusal, or thinking. Also, I had to find some good use for that HP-55 I had bought on impulse. (The XYL says the main difference between men and boys is the price of their toys.)

My math was too rusty to rely on, so I engaged a friend

City	Lat.	Long.	Azimuth
Bogota	4.5	-74.3	158.6
Calcutta	23.6	88.4	4.0
Canton	23.1	113.3	339.3
LaPaz	-16.5	-68.4	158.8
Perth	-32.0	115.9	290.3
New York	40.8	-74.0	91.5
Los Angeles	37.8	-122.4	272.9

Table 1. Practice examples (azimuth from Chicago: 41°52' N., 87°38' W.).

and math major to help develop a formula which not only could be programmed with a minimum of key strokes, but also permitted the calculator (not me) to determine the short path with a test and conditional branch. The basic formula is included in case you need to modify the instructions for a different instruction sequence (the algebraic vs. RPN system). For Hewlett-Packard and probably other RPN types, you can go right to the program.

The HP-55 has a clock for timing QSO IDs or can be used for metric and temperature conversions needed for foreign contacts. One precaution: Run the ac charger cord through grounded braid if there are large rf fields around. A further suggestion: Determine the azimuths to a few places in the manner you currently use, take this program to your friendly calculator dealer and have him check you out before you spend your money.

The basic formula is:

* * * * * * * *

$$\text{Azimuth} = 270 + \tan^{-1}\left[\cos\lambda_1 \quad \frac{\tan\lambda_1 \ \cos(l_2 - l_1) - \tan\lambda_2}{\sin(l_2 - l_1)}\right]$$

* * * * * * * *

where

λ_1 = latitude of QTH
l_1 = longitude of QTH
λ_2 = latitude of distant station
l_2 = longitude of distant station

The procedure to follow is simple. The PRGM switch places the calculator in the learn position. The program is loaded into memory by keying in the strokes listed on the Program Form. The switch is placed in the run position, the BST button sets the program at the starting point, and you are nearly ready to start. There is some information that must be loaded into memory (because there wasn't room in the program for it and it can change for different QTH locations). This information is the QTH latitude, cosine of this latitude, QTH longitude, and two constants, 180 and 270. The formula was derived with *east* longitudes and *north* latitudes being positive numbers. The CHS (change sign) key must be used for *south* latitudes and *west* longitudes. Maybe that doesn't sound too simple, but it is only done one time. From then on the calculator displays the short path azimuth to any point if the latitude of the remote location is entered (ENTER), followed by the longitude, and the pressing of R/S.

The calculator can be left on in the shack and used to perform other calculations without affecting the stored program.

If the difference of longitudes $(l_2 - l_1)$ lies between zero and 180 degrees, then 180 must be subtracted to get the short path azimuth. Also, to avoid the denominator becoming zero (division by zero not allowed), some small amount can be added to the home QTH longitude (like 0.00001) when that constant is entered.

The following example happens to be the same as that in the ARRL *Antenna Handbook*. What is the azimuth from Chicago to Cairo? (Chicago: 41°52' N, 87°38' W) Converting to decimal degrees, key in 41.87 STO 1, f cos STO 2, 87.63 CHS STO 3, 180 STO 5, 270 STO 6.

To find the azimuth from Chicago to any place, key in the other place's latitude and longitude, available from an atlas, map, or world almanac. (Cairo: 30°00' N, 31°14' E) Key in 30 ENTER, 31.23 R/S, and read the answer displayed as 49.35° or 49° 20', the clockwise azimuth from true north. ■

CONTESTS

from page 15

2 meter bands, but repeater contacts are not allowed. Only one transmitter in operation at one time and no crossband contacts. Phone and CW are separate contests and must be scored as such.

FREQUENCIES:
Phone – 1850, 3950, 7235, 14330, 21365, 28525, 51000, and 2 mtr simplex. CW – 1810, 3535, 7035, 14035, 21035, 28035, 50050, and 144050. Novice – 3725, 7125, 21125, 28125. Please do not interfere with any nets or other traffic sessions!

EXCHANGE:
MINN stations send RS(T) and county; others send RS(T) and ARRL section or country.

SCORING:
Score 1 point per QSO, Novice QSOs count 3 points. MINN stations multiply points by number of sections and DX countries (NOT US or Canada). Others multiply QSO points by number of MINN counties (87 maximum). Any stations using 250 Watts or less multiply final score by 1.5. Special events call station will count 5 points per QSO.

ENTRIES:
Logs must include: date, time (GMT), band, mode, and contest exchange. Stations making 50 or more QSOs must include a check sheet for each band and mode. Usual disqualification criteria. Logs must be postmarked by July 2nd and received by July 9th to be eligible for awards. Mail entries to: HARC, c/o WBØMAO Steven J. Gardner, PO Box 261, Staples, MINN 56479. Please include your rig description and an SASE for results.

RSGB NATIONAL FIELD DAY
Starts: 1700 GMT
Saturday, June 12
Ends: 1700 GMT
Sunday, June 13

The only eligible entrants for this contest are G, GC, GD, GI, GM, and GW stations. However, overseas stations are welcome to submit check logs. A certificate will be awarded to the overseas station in each continent whose check log shows he has contributed the most points to competitors. All contacts must be on CW only using the 160 to 10 meter amateur bands. Each station may be worked once on each band but crossband contacts are not allowed.

EXCHANGE:
RST and QSO number.

ENTRIES:
Logs must show date and time in GMT, callsign of station worked, and exchange sent and received. Use separate logs for each band and only use one side on each sheet. A cover sheet must also be included showing contest name, date, claimed score, callsign, name, address, station details, and signed declaration (standard declaration). All entries should be addressed to: RSGB HF Contest Committee, c/o D. Thom G3NKS, 20 Bramble Close, Copthorne, Crawley, Sussex, ENGLAND, RH10 3QB. All entries must be postmarked no later than 15 days after the contest.

WEST VIRGINIA QSO PARTY
Starts: 0100 GMT Saturday,
June 12
Ends: 0059 GMT Monday,
June 14

All amateurs are invited to participate in the QSO Party sponsored by the West Virginia State Radio Council. There are no operating time limits during the contest period. The same station may be worked on different bands for additional points, but only once per band regardless of mode. West Virginia stations may work each other.

FREQUENCIES:
35 kHz up from the bottom edge of each CW band and 10 kHz inside the general portion of each phone band.

EXCHANGE:
QSO number; RS(T); and county (if WVA), state or country.

SCORING:
A power multiplier will be allowed as follows: 200 Watts or less dc input = 1.5; over 200 Watts dc input = 1.0. Out-of-state stations determine their score by multiplying the number of QSOs times the number of different West Virginia counties worked (55 max). This total is then multiplied by the power multiplier as defined above for the total score. West Virginia stations multiply the total number of QSOs by the sum of the different WVA counties, US states, and ARRL countries worked. This result is then multiplied by the power multiplier to determine the final score.

AWARDS:
To be eligible for an award, a station may have only one unassisted operator. Awards will be issued to the highest scoring WVA station, 1st runner up in WVA, 2nd runner up in WVA, highest scoring station in each state, and the highest scoring station in each country. Decisions of the Contest Committee of the West Virginia State Radio Council will be final.

LOGS/ENTRIES:
Logs must indicate date, time, QSO number, callsign, QSO number received, signal reports, and county, state or country of the station worked. Indicate the mode and band also. Logs should be sent to: West Virginia QSO Party, P.O. Box 299, Dunbar, West Virginia 25064. Logs should be received no later than July 17th, and no logs will be returned.

ARRL VHF QSO PARTY
Starts: 1900 GMT Saturday,
June 12
Ends: 0600 GMT Monday,
June 14

Check the May issue of QST for any last minute changes!

Entrants may operate no more than 28 of the 35 hours during the contest period. The seven hours off-time must be taken in increments of 30 minutes or more. Listening time counts as operating time. All contacts must be made on amateur bands above 50 MHz using authorized modes. Fixed, portable, or mobile operation under one call, from one location only, is permitted. Any transmitter used to contact a station may not be later used to contact another station during the contest period with any other callsign. Contacts made by retransmitting either or both stations (such as repeaters) do not count for contest purposes. Each contact exchange must be acknowledged by both operators before either may claim contact points. A one-way confirmed contact does not count.

EXCHANGE:
Exchange simply ARRL section.

SCORING:
On 50 or 144 MHz count 1 point per contact; on 220 or 420 MHz count 2 points per contact; on higher UHF bands, count 3 points per contact. Final score is then the total QSO points multiplied by the number of different bands for additional credits but crossband contacts are not allowed. Also, aircraft mobile stations cannot be counted for section multipliers.

ENTRIES:
All logs must be postmarked no later than July 7th and sent to: ARRL, 225 Main Street, Newington CT 06111. Logs and entry forms are available through this same address; please include an SASE. Usual awards will be issued and the standard disqualification rules will apply.

ARRL FIELD DAY
Starts: 1800 GMT, Saturday,
June 26
Ends: 2100 GMT Sunday,
June 27

Rules are generally lengthy (2 pages in *QST*); please refer to the May issue of *QST* for detailed information and for any changes since last year's rules.

Briefly, the general rules are as follows:

The contest is open to all amateurs within the ARRL sections; foreign stations may be contacted for credit but are not eligible to compete. Each entry will be classified by type of operation: Class A – Club group set up specifically for Field Day operation operating portable without commercial power; Class B – Non-club stations set up portable without commercial power; Class C – Mobile stations; Class D – Fixed stations using commercial power; Class E – Fixed stations using emergency power for transmitters and receivers.

All entries will further be classified by the number of transmitters utilized. Class A and B stations not beginning to set up before 1800 GMT on Saturday may operate the entire contest period. All others may not operate more than 24 hours total. Each station may be worked once on each band; voice and CW are considered different bands (all voice contacts are equivalent and RTTY = CW).

Class A, B, and C stations may contact anyone, but classes D and E must contact only Class A, B, or C.

EXCHANGE:

RS(T) and ARRL section or country.

SCORING:

Phone contacts count 1 point each and CW contacts count 2 points each. Final score is sum of QSO points times multiplier for highest power used at any time during the contest period, plus bonus points.

Power multipliers: Multiply by 5 if 10 Watts or less dc input power and non-commercial main power source or motor driven generator; multiply by 2 if less than 200 Watts; multiply by 1 if over 200 Watts up to 1 kW; multiply by 0 if over 1 kW (note – dc power on SSB is half PEP power).

Bonuses: (only for Class A or B stations) 100 points for 100% emergency power; 100 points for "natural" powered contact (only one QSO req'd); 50 points for public relations; 50 points for message origination for SCM or SEC; 5 points for each message received and relayed during FD period up to a maximum of 50 points; 50 points for completing at least one QSO on CW via OSCAR.

ENTRIES:

Standard disqualification rules apply. All entries should be sent to: ARRL, 225 Main Street, Newington CT 06111. Official log and entry forms are available from the same address for an SASE.

NOTE: ARRL policy is not to release information on ARRL contests until publication in QST. *Since this is too late for publication in* 73 *Magazine, I will continue to list rules on all ARRL contests based on the previous year's contest rules with reference to the appropriate issue of* QST *to check for any changes or updates. All other contest information will be the latest available at press time. – Bob WA1SCX*

HAM HELP

I will be glad to help with any phase of amateur licensing. We hold continuing education classes for ham licensing whenever demand warrants. Interested parties are invited to visit the school's club station, or feel free to call.

Richard Bley WB4GVA
Catawba Valley Technical Inst.
Hickory NC 28601
(704) 327-9124

I would be very happy to be of assistance to any prospective ham in this area who is in need of help.

David A. Deem WA3ZXI
8 Hawthorne Lane
Rosemont PA 19010
(215) 525-2684

Please add my name to your ham help list. I would also like to know if you know of any clubs in this area.

J. Bryan Loofbourrow
PO Box 1237
Mountainside NJ 07092

Wanted: adjustment/installation instructions for Hy-Gain TH-2 3-band 2 element beam antenna. Believe this antenna was built about 15 years ago – it uses blue phenolic traps similar to "slim line" traps in 12AVS vertical.

William W. Muessig K4FD
3156 Graham Road
Falls Church VA 22042

I would appreciate a manual or a copy of the schematic diagram of a Model 103B Hewlett-Packard oscilloscope. I will be glad to pay for copies and postage.

Claude Blakeslee WB6GHZ
C/O Mills High School
400 Murchison Drive
Millbrae CA 94030

Help!

Leonard J. Vanella
172 Irving Ave.
Floral Park NY 11001

I'll be glad to help newcomers.

Ross N. Dunnihou WN5MZZ
516 S. Cedar Box 134
Shattuck OK 73858

I need help!

William Cranford

Tracking the HAMBURGLAR

SWIPED: SBE – Linear Systems #SB 36, professional type amateur radio transceiver with #SB 36-ACP speaker and power supply. S/n 71128, base station, brushed chrome face, black cabinets. Courier #COP 50 HL, VHF monitor radio, hi and lo band. Brushed chrome face and knobs, black body. Courier #COP 75, VHF automatic scanner, hi band. Brushed chrome face, black body. These items were taken January 26, 1976 from South Fork Electronics Corp., 36 Hampton Road, Southampton NY.

SHANGHAIED: HW-202 transceiver s/n 09512. Has following crystals installed: 07-67, 34/94. Had WB0QGF engraved on outside and inside. Joel Humpke WB0QGF, 516 Zion St., Aurora CO. Taken March 1, 1976 from parking lot of radio station KLMN.

ROBBED: Standard 826M s/n 010230, Cobra 200 s/n 30900140 (220 MHz rig). Both modified with type N rf out connectors. Contact WA2CSE, 516-546-2571.

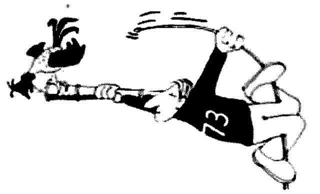
STOLEN: Clegg FM-278 s/n 27043-1649 taken in Huntington, New York on February 21, 1976. Also Touchtone pad and tone burst generator in minibox. Report to Suffolk County Police 2nd Precinct or call Dave Metal W2FTH, home 864-1130, or business 368-2200.

ABDUCTED: Clegg FM-DX, 2/19/76; Boston, Mass. Slide bracket riveted to top, s/n -056-, Police ID #141449314PTH. WB2ZSD – Call 201-263-0376, anytime.

FILCHED: Realistic pocket scanner has SSN 095-42-1177 engraved on set. Stolen February 29, 1976 at PPRAA Swapfest, Peterson Field CO. Please notify police dept. or James R. Einolf, 12149 N. Piney Ln. Rd., Parker CO 80134, 303-841-2105.

LOOTED: Icom 230 s/n 2403831 taken from my car on 2/21/76 in Bellows Falls, Vermont. Anyone using it after that date will self destruct! Tom Abare K1VNE, 22 Lockwood Street, Bellows Falls, Vermont 05101.

Looking West



from page 25

your problem and offer simple concrete suggestions towards finding a quick solution. Most of all, he is dedicated to uniting the diverse factions and geographic areas administered by SCRA and thereby to building SCRA into an organization that will serve the needs of all members as well as those who are now non-members operating unsanctioned, uncoordinated systems. His goal seems to be one of "promoting coordination through promoting friendship."

He has already taken some affirmative steps in that direction including dividing the existing technical committee, heart of SCRA, into two sub-committees. Staffed by the best expertise he could muster, those involved with the development of two meters administer the affairs of two meters, and in a like manner, those involved in 220 MHz are determining the future of that band. The best experts of each are working toward a bright future for each.

"Why do this?" you may ask. Simply, who knows more about 220 MHz than those pioneering it at this time? If growth and development of that band are to avoid all the pitfalls and headaches that befell the growth of 2 meters, then it must have the proper guidance. Fred Deeg K6AEH of WR6AFM is head of the 220 task force sub-committee that will oversee this development.

At present, Bob himself is heading up the two meter sub-committee (I told you he was the kind of person that indeed does get involved), and has gotten hold of some of the finest talent in the two-way communication industry, who also happen to be amateurs concerned with the positive growth of VHF, to serve on this committee. I have already noted the part that Jim Hendershot will play, and in addition to Jim, you will find such people as Ray Vonnuman K6PUW, Neal McKie WA6KLA, and a myriad of others selected for their technical ability and overall knowledge of the problems of the geographic areas they represent.

The basic purpose and intent of SCRA has not changed. It is still the same organization that started four years ago to iron out the mess that was two meters in Southern California before its arrival. People like Dick Flanagan, Skip Clark, and Bill Carpenter have taken it from its very infancy to where it is now. In the process, much was accomplished, and at the same time many mistakes were made. From these mistakes, though, has come possibly the most viable of all coordinating organizations to be found anywhere in the nation, one that I personally feel proud to support. SCRA learned from its mistakes, was never too proud to admit that they were made, and has used this accumulated knowledge to benefit the entire Southern California FM community. Now with a broad based new directorship, this organization is again out to conquer new horizons and faces the future hoping to bring more constructive coordination to the Southland. All they ask is the continued support of those who have worked to build the organization, and more important, the support of those who intend to work toward future development of two and 220. Maybe the term "pirate repeater" will soon be a thing of the past here in the Southland. It's a good goal to work towards.

This then brings us to another important topic, but also brings a problem for yours truly. It involves a coordinated repeater facing interference from the users of an uncoordinated system that took up operation on the same channel pair. "Why then," you may ask, "should this cause old 'ITF' a problem?" Well, you see, I happen to be involved with one of the two systems in the controversy (the coordinated one, thankfully) and am therefore torn between my outlook as a repeater user and maintaining my credibility in this column.

Therefore, I hope that the following is a solution to my dilemma, and one that meets with your approval. Rather than personally commenting on the matter, I am writing to the licensees of WR6ABB – PARC, Los Angeles (coordinated), and WR6AFR – Juniper Hills (unsanctioned). I will publish the response of both *unedited.* I will also publish the final report of the SCRA technical committee and thereby permit you to make your own judgments and find your own conclusions.

As a member of the board of directors of the Palisades Amateur Radio Club, owners of WR6ABB, and a control station for that system, my personal views on the matter must remain mine, and I hope that the method I have chosen to report on this meets with your approval and more important, that it thereby permits me to retain my credibility in your eyes. Believe me, it is a very tough position to find oneself in and I hope you never face the same problem.

As usual, we have run out of space before running out of topics. No, we didn't forget our Guatemala wrap-up, the complete AJP story, the latest in public relations, and a myriad of other things. At least you know we will have some goodies for you next month. See you then.

NOTE: The Pottstown Area Repeater Team Hamfest and Flea Market, to have been held on May 23 as listed on page 128 of our May issue, has been canceled.

DULUTH MN
MAY 8

The Twin Ports FM Club swapfest will be held May 8 from 11 am to 3 pm at the First Methodist Church, 6th Ave East and Mesaba Ave, Duluth MN. Talk-in 34/94. Advance registration \$1, at the door \$1.25, booth space \$.75. Write WAØBJY for more information.

JUNE 6

The Tri-County Radio Association Inc., flea market will be held June 6, 1976 at Nick's Grove, 318 William Street, Piscataway NJ. Opens at 10 am, admission $1, tables $4, half tables $2. Door prizes. Talk-in 146.52, 147.855/147.255. For further information call (201) 725-0778 or (201) 752-4307 or write: PO Box 412, Scotch Plains NJ 07076.

PRINCETON IL
JUNE 6

The Starved Rock Radio Club Hamfest will be held June 6 at the Bureau County Fairgrounds, Princeton, Illinois, same place as last year. Free coffee and doughnuts from 10 to 10:30 am. Camping and trailer space on a first come first served basis for a nominal fee. Official dedication of Starved Rock Repeater by ARRL officials. Advance registration, $1.50 until May 20, after that/or at gate $2.00. For more complete information, motel list, maps, etc., furnish long SASE. For reply, write: Starved Rock Radio Club W9MKS, RFD #1, Box 171, Oglesby IL 61348. (815) 667-4614.

SIOUX FALLS SD
JUNE 12-13

The Sioux Falls Amateur Radio Club, Inc. and the Sioux Valley

Repeater Association, Inc. will hold the 1976 South Dakota Ham Picnic in Sioux Falls on June 12 and 13 at the Sioux Empire Fairgrounds on Sioux Falls' west side, ½ mile east of Interstate 29 and the 12th Street off ramp – follow the "OSY" signs. A talk-in will be on 3950 kHz by the S.F.A.R.C. Club station, WØZWY. Members of the S.V.R.A. will provide information and assistance on the WRØACK 16/76 repeater. For further information, please send an SASE to Sioux Falls Amateur Radio Club, PO Box 91, Sioux Falls SD 57101.

ATLANTA GA
JUNE 12-13

The ARRL Southeastern Division Convention and the Atlanta HamFestival 1976 will be held on June 12-13th at Dunfey's Royal Coach Motor Hotel, I-75 at Howell Mill Road, Atlanta GA. Special HamFestival rates of $16 single, $21 double are in effect. Individual registration is $3 in advance, $4 at door; family registration $5 in advance, $6 at door. Flea market spaces (outdoors) are $5 each, first come, first served. For more information and pre-registration forms, write: Atlanta HamFestival 1976, 53 Old Stone Mill Road, Marietta GA 30062 or telephone area (404) 971-HAMS day or night.

WILLOW SPRINGS IL
JUNE 13

The 19th Annual ABC Hamfest will be held Sunday, June 13, 1976 sponsored by the Six Meter Club of Chicago, Inc. Located southwest of Chicago at Santa Fe Park, 91st and Wolf Road, Willow Springs IL. Advance registration $1.50; at the gate $2.00. Large swap row, picnic grounds, AFMARS meeting, refreshments. Advance tickets from Don Marquardt K9SOA, PO Box 79, Lyons IL 60534 or any club member. Talk-in on 146.94 FM or WR9ABC 37-97 (PL2A).

GRANITE CITY IL
JUNE 13

The Egyptian Radio Club, Inc., W9AIU Hamfest will be held Sunday, June 13, 1976 at the club house located north of Granite City, Illinois, ¼ mile south of the Old Chain of Rocks Canal Bridge. Swapper Row, games for the kiddies, lunch served, cold drinks, ladies' white elephant sale and Bingo. Talk-in on AF9ACA 146.76. Admission free.

ARNOLD MD
JUNE 13

The Maryland Mobileers Amateur Radio Club will hold its Sixth Annual Hamfest on Sunday, June 13, 1976 at Anne Arundel Community College, Arnold, Maryland. Gates open at 9 am. Registration: $2. Tailgaters: $3 plus registration fee. Drawings to be held at 3 pm. First prize: $200 Savings Bond. Talk-ins on 146.10/.70 – 146.52 – 146.16/.76.

AKRON OH
JUNE 20

The Goodyear Amateur Radio Club WA8UXP of Akron, Ohio will hold their 9th Annual Fathers' Day (Hamfest Picnic), on June 20, 1976, at Wingfoot Lake Park located east of Akron, Ohio, one mile west of Suffield, Ohio, on County Rd. #87 and near County Rd. #43. Huge flea market, displays, swap and shop, prizes on the hour, picnic tables available. Adult and children's play area all day. Join us for an enjoyable day of entertainment. Hours: 10 am to 6 pm. Family admission $2 prepaid; $2.50 at gate. For details, tickets, map and program, write to Floyd T. Gilbert WB8ALK, 1976 Newdale Ave., Akron, Ohio 44320.

DUNSEITH ND
JULY 10-11

The 13th Annual International Hamfest is scheduled for July 10 and 11, 1976 at the International Peace Garden between Dunseith, North Dakota and Boissevain, Manitoba. Many prizes to be won. For more information write: Craig R. Schmidt WBØGFZ, Co-Chairman, 1976 Hamfest, Reed Hall #302, North Dakota State University, Fargo ND 58102.

TERRE HAUTE IN
JULY 18

Turkey Run Hamfest has MOVED! New location is the Vigo County Fairgrounds on Highway 41 just South of Terre Haute. There will be prizes galore, lots of flea market space under a roof, XYL Bingo, and plenty of overnight camping will be available. Presale tickets are available 4 for $5 or $1.75 ea. At the gate 3 for $5 or $2 ea. For further information or tickets write to Wabash Valley Amateur Radio Assn., P.O. Box 81, Terre Haute IN 47808.

CANTON OH
JULY 25

The Tusco Amateur Radio Club and the Canton Amateur Radio Clubs are holding their Second Hall of Fame Hamfest on July 25, 1976. It will be held at the Stark County Fairgrounds, Canton, Ohio. This weekend, by the way, is the weekend of the National Pro Football Hall of Fame Football Game and Parade.

MENA AR
SEPT 4-5

The Queen Wilhelmina Hamfest 1976 is Saturday and Sunday, September 4 and 5, at Queen Wilhelmina State Park, Rich Mountain, Mena, Arkansas. Excellent accommodations and food at the newly restored historic Queen Wilhelmina Castle. Door prizes hourly, grand prize, new equipment displays, flea market, camping area with utilities and rest rooms, amusements for harmonics. Talk-in 146.52. For more information write WB5CXX, P.O. Box 5191, Texarkana TX or phone (214) 838-0625.

considered; therefore, at this level, inputs from them must also be solicited and carefully analyzed. Inputs from other nations and the technology being developed by them might not be bad to know, and an open invitation to a representative from Europe or another part of the world could go a long way in cementing relations between us. We might just learn a little from their work. Think I am kidding? Just look at the latest *73 World Atlas of Repeaters.* They're right in there with us.

It would be important to us to develop an ongoing and open dialogue with the Federal Communications Commission, and a representative of the Amateur and Citizens Division should be invited to attend every one of these meetings. With deregulation now a reality, it is very important for them to know that we are willing and able to be the self-directing service that we want to be and that we have developed the necessary structure to insure this. By inviting both their participation and comment at such meetings, we can help foster this deregulation trend, since they will then be getting regular feedback on how things are going (and getting this directly from those chosen by us to represent us). If you lived through the years of 18803 (you can see that repeaters and FM are my special interest) and never want to see a repeat of things such as this, then an ongoing dialogue on a national level between the Commission and the amateur community is essential.

Finally, it is important to let the Directors of the League know what our wants and desires are, so that they can be directed to work toward these goals. At the same time, they too might have ideas on the same subjects that they wish to put forth to us. For this reason, a direct dialogue between the ARRL Board of Directors and this top drawer committee must also exist. While some may not believe it, in the past few years there has been a marked shift within the League management toward listening to and acting upon the many diverse needs of the amateur community. However, they can only act if input is provided, and for that reason a direct liaison between the two is mandatory. It was seeing this change begin that gave rise to my decision to join the ARRL – and, hopefully, help foster its continuance.

So there you have it: a voluntary coordination plan that encompasses all interested amateurs, provides for the needs of all modes and all special interests, is totally elective in nature, and offers the possibilities of international ties. A pipe dream you say; maybe so, but with a little work and commitment on the part of each individual amateur, it or something similar can be a reality. I do not offer this as a solution to the problems that plague us now or that will plague us in the future, but rather as a starting point from which to build. Let's exchange ideas and come up with a plan that not only will benefit us now, but also will never become obsolete in the future.

This leaves us with two questions (perhaps many others, but these two seem key). Where did I get this idea? And, is it really all that necessary? The where is easy: It is nothing more than the ideas of many amateurs with whom I have spoken who are concerned about the future. All that I have done is take their views and my own and collate them into some viable form – some starting point from which to build. But is it necessary to do so? At this moment, the answer is yes and no, depending upon where you happen to live. If it's in an area with a limited number of amateurs and limited VHF activity, the answer is no. However, the majority of this operation is concentrated in large and crowded urban areas, and in some places we are beginning to step on one another's toes. This can only lead to dissension within our ranks, unless we do something now. If this is to be the case, we must be farsighted enough to give all involved some voice, and must be democratic about the way we handle such an effort. We must not appoint from outside but rather be left free to determine our own destiny through due democratic process. What you have just been presented is, I hope, a true "Representative Democratic Republic" with which to begin preparing for the future.

In closing, let me pose the following. For many a moon we hollered for deregulation so that we would be free to continue building toward a free and viable amateur radio community. The Commission has now started to grant our requests, so I only ask if we are prepared to meet and accept both the challenge and obligation that this puts before us. Individually we cannot do it alone, but collectively, on a voluntary basis, the future can be bright and fruitful.

Your comments, and ideas and recommendations are gratefully accepted.

LETTERS

from page 113

interested in transistors? The stuff in BYTE is so far over my head that I don't really look on that as being helpful to most of us . . . and it certainly isn't ham oriented. Okay? Now stop fussing and start reading those articles . . . we've gone to a lot of trouble to get them into the magazine so you will know what is what with this new equipment . . . the most amazing component in the history of electronics. — Wayne.

RINGING A BELL

J. K. Bach's article in the March issue of *73* rang a bell. I hope this information will be useful to other ten dollar calculator buyers.

The "Accumatic" calculator I bought several years ago (for considerably more than ten dollars, unfortunately) was marketed by Lloyd's Electronics, Inc., 18601 S. Susana Road, Compton CA 90211. My calculator was exactly like the one Mr. Bach bought for ten bucks — it didn't work either. The problem was a shorted capacitor — C8 — which prevented the display from clearing. By replacing C8, I finally got rid of the 8s, and the display zeroed nicely. Since the instruction manual I received with the calculator was even more vague and incomplete than the one the author describes, I was content with an operating display and reasonably good battery life. The "Accumatic" performed fairly well, if slowly, for the next few months until I sold it and bought one of the fancier models with a memory and square root functions.

John C. Mutzabaugh WNØQEA
Grand Forks ND

P.S. By the way, I thoroughly enjoy *73* — if more hams had your attitude, the future of amateur radio would be a hell of a lot brighter.

RFI LEGISLATION

On 25 February 1976, The Honorable Barry Goldwater (Arizona) introduced radio-frequency interference (RFI) legislation into the U.S. Senate. The bill, S. 3033, is virtually identical to the RFI bill introduced into the House of Representatives last year by Mr. Charles A. Vanik.

Mr. Goldwater's bill has been referred to the Senate Commerce Committee, and so, interested readers should forward their comments on the bill to: The Honorable John O. Pastore, Chairman, Communications Subcommittee, Senate Commerce Committee, United States Senate, Washington, D.C. 20510.

Letters may also be sent to one's senators at the following address: The Honorable . . ., United States Senate, Washington, D.C. 20510.

Correspondence should indicate that a similar measure is awaiting hearings in the House of Representatives (H.R. 7052).

Theodore J. Cohen W4UMF
Secretary
RFI Task Group
Alexandria VA

MAPLE HILL

"This is W5LSF, Rockwall, Texas, near Dallas . . . we read you loud and clear . . . greetings to the Castleton Kiwanis!" This message filled the hall where the Castleton Kiwanis club met recently as students Jim Zalinka and Ann Ryan joined me in a demonstration of "ham" or amateur radio. Joining the Kiwanis at the invitation of Mr. Harry Hallenbeck, my students and I set up two portable stations using equipment and antennas made by Maple Hill High School's Amateur Radio Club. After explaining the workings of their school station and showing cards collected from stations "worked" all over the world, the students distributed free literature and gave a demonstration. Despite bad weather and band conditions, the station near Dallas was contacted as part of the demonstration on "DX" or distance communications. Another demonstration showed local FM communication, using repeaters.

As part of their training for radio licenses, a group of 5 Maple Hill students recently visited amateur radio operator Joseph Battaglia W82QEH of Schenectady, who's been on the air since 1918. Joe showed his equipment to students Geoff Schad, Bob Porter, Al Ferreira, Scott Van Nederynen and Jim Zalinka, who accompanied me on the visit. Joe was particularly proud to show how he restores old radio equipment and experiments with new antennas, both prized amateur radio skills.

Maple Hill High's radio station and program have recently been recognized by two national amateur radio magazines, *QST* and *CQ*.

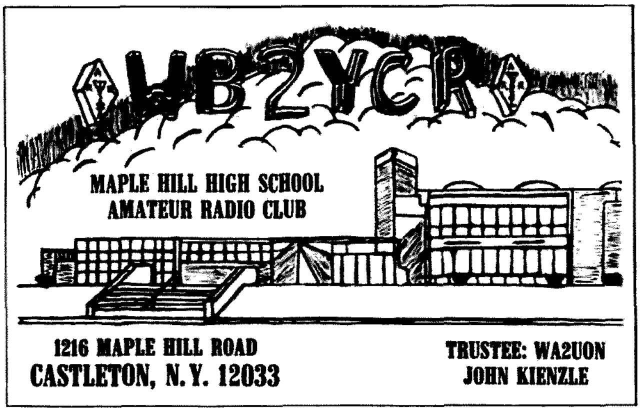
Castleton NY



SAD PARAGRAPH

OK, here it is. Your sad paragraph in your editorial about the reader service card got to me. I have circled the appropriate alphanumerics and am writing this, my first letter ever to a magazine. It's just that I like *73* a lot and would like to make your advertisers happy. As you will note from the checked box, my copy was obtained at a newsstand (ham store). This is because of thiefs in my apartment house. It seems they like all the same mags that I do, so I am forced to buy at the store. Well, that's life.

Keep up the computer articles. I am about to buy an Altair 8800 and my knowledge of computers is about equal to yours, so I need all the info I can get. Thanks for a swell mag.

R. L. Turner K7MRB
Seattle WA

DOLLAR FOR DOLLAR

Your new format has certainly improved the appearance of *73 Magazine* and made for much easier reading with the larger print. Congrats!

I would like to hear from any of your readers who are ham operators and former members of the Lone Scouts of America.

August Karvonen K8HHZ
Mass MI 49948

Thought I would drop you a line and let you know that I really enjoy your new format for *73 Magazine*. Dollar for dollar it is still the best radio magazine around. Keep up the good work. I really enjoy reading your editorials, as they sometimes step on toes that need to be stepped on.

I operate CB here as well as ham radio, and I find most of the people here in this area very conscious of proper procedure and identification with the proper callsign as issued by the FCC. Not all of us CBers are bad. I have been a licensed ham for 16 years and have found a use for both ham radio and CB radio in my personal and professional life.

Billy L. Nielsen WB4APC
Radcliff KY

HBØ DXPEDITION

Please be advised that the Wiesbaden Amateur Radio Club is planning an HBØ Dxpedition. Dates are from 26 May 76 through 2 June 76. We will be using an HBØ call as a club call.

The bands worked will include the following: 80, 40, 20, 15, 10 and 2 meters. Frequencies to be used are not firm and we do plan to operate in the Novice portion of the bands.

QSL will be via the German DARC and DA1DM, or as given during QSO.

Dennis F. Miller WB5KEA/DA1DM
APO NY

THEY'LL BE THERE

Are you following us around? Last summer, just after we opened a CB shop, you came up with a ham who suggested us amateurs open CB shops. Now comes your April issue — asking about CB bootleggers on 10 and 15. Ron (W5SUH) and I (WN5PKE) also sell and service ham equipment. Sideband has proven fascinating for some of our CB customers, and since we keep ham equipment on display, they ask about it, also.

With this group, Ron has made it so interesting that they've started Novice classes. Last night we had 18 members in the class. Pretty good for a farming community of 2400, don't you agree? Some of these CBers drive 60 miles one way for this class.

The answer? Make it sound and *be* interesting — start explaining, and take time to convert them.

As I'm writing this, one of our students is reading your article. He says, "Tell them I agree — let's keep those of us who don't know anything off until we *do* know what we're supposed to know."

We've met with so much more interest from these more-intrigued CBers than we have from the general public. Can we hams look at the CBers as a "natural resource," waiting to be tapped?

Look for our students in the '77 callbook. They'll be there!

Carol Gamel WN5PKE
Checotah OK

NEW PRODUCTS

NEW WILSON 1405SM THOROUGHLY TESTED

Wilson has come up with a five Watt HT . . . shades of the old Motorola HT-220 for you old timers in FM. The Wilson has the enormous benefit of having a 1 W/5 W switch so you don't *have* to run the battery down at the high output rate.

Naturally I felt that it was important to put the Wilson through a really rigorous test. After a lot of thought, the decision was made to check it out under the worst possible conditions . . . while skiing at Aspen, Colorado. Here it would have to be subjected to temperature extremes, altitude extremes, long periods of use without recharging, plus plenty of physical abuse whenever I fell down on it.

Aspen would be a great two meter FM area if there was a repeater set up on a mountain across town. The four main ski areas are all in a row, running about ten miles from the center of town. The result is that when one is skiing on one side of a mountain at one end of the chain it is difficult to get through to someone skiing on the other side of a mountain on the other end of the chain. This is where the five Watts really turned the trick. Time after time I was able to shake up the troops several mountains away by blasting them with the high power position.

The unit sucks 900 mA in "high" so prudence calls for moderation and use of the 1 W level when the 5 W isn't actually needed. It only drags 400 mA in low.

A friend of mine once pointed out that "for a few cents extra you go first class." He was right, in general, and thusly I had the TT pad on my 1405SM. Now, I'll admit that there are not a lot of autopatch repeaters in Aspen . . . none, in fact. But that in no way stopped me from expansively pointing out to any non-ham who showed even slight interest that, oh yes, we could make telephone calls with the HT.

It's funny about an HT . . . you can go along for years not owning one and in some way get by. But once you have it you find that it is in constant use. Some chaps wear the damned things almost 24 hours a day, which to my mind is carrying hamming too far. Most of these chaps are single . . . or at least they are single now.

The 1405, being a bit smaller than the older Wilson HTs, fit even better into my ski parka pocket. I didn't take any spectacular flops on it, but I did manage to check out its survivability under impact a few times . . . like the time I came sailing into the middle of the bus stop area at the end of the day going at an impressive clip . . . I did a quick hockey stop in a casual and very masterful way . . . and caught the edge of my ski in a rut and went skidding on the HT over the ice for about six feet. Damned people didn't have anything better to do than stand around snickering. The HT worked fine.

I like the Wilson because it is easy to get into for changing crystals . . . it has six (6) channels, which is very handy if you are going to be around a few repeaters and also need a couple of direct channels. The batteries are very easy to access . . . this was particularly valuable for me because my charger got swiped from my hotel room within a couple hours of my arrival in Aspen, and I had to jury rig a charging setup with a couple clip leads into a Motorola charger. It kept me on the air. I did find that when I kept to the 1 W position I could use the HT for two or three days before the battery meter began to indicate a weakening condition. I left it on receive all day so I could hear any calls from the other four skiers.

A group of amateurs with HTs is a fun thing under almost any circumstances . . . and skiing is particularly great. Even though you are divided up and not skiing together, you are in constant touch.

Wayne Green W2NSD/1

VHF ENGINEERING ANNOUNCES TWO NEW POWER SUPPLIES

VHF Engineering, of Binghamton, N.Y., has announced two new high current, regulated 12 volt power supplies for use in amateur and commercial applications.

The two supplies have ratings of 15 Amps and 25 Amps, over voltage ranges of approximately 10-14 V dc and 10-14 V dc respectively. Load regulation is 2% from no load to maximum rated current.

These new supplies feature both over-voltage protection and foldback current limiting. The over-voltage protection is provided by a crowbar circuit which will shut down the supply if the output voltage exceeds 14 V. This feature protects the equipment being powered from damage due to over-voltage in the event of a malfunction within the supply. The foldback limiting circuit limits the output current to a maximum of 1 Amp in the event that the output is shorted. This feature protects the power supply from damage and prevents high currents from flowing into a piece of equipment which has developed an internal short. When the short is removed, the power supply returns to normal.

These regulated power supplies have been designed to high commercial standards through the use of epoxy glass, tinned circuit boards, along with high quality components. They may be purchased directly from VHF Engineering, 320 Water St., PO Box 1921, Binghamton NY 13902, or from distributors nationwide. The 15 Amp supply (PS-15C) sells for $79.95 in kit form and $94.95 wired and tested. The 25 Amp supply (PS-25C) sells for $129.95 as a kit and $149.95 wired and tested.

George R. Allen W1HCI

MORE ON THE TWO-TIMER

(April, 1976, p. 106)

Nexus Trading Company will provide a free information package with board layouts for the Two-Timer clock, upon receipt of an SASE. An etched and drilled board set is available for $8.95. Specify .3" or .6" readouts.

briefs

The WC calls you may begin to hear soon on the ham bands aren't Novices in the Caroline Islands or newly licensed hams; they are RACES calls. In the Report and Order on Docket 19723, the FCC rewrote the RACES rules to affirm that all such stations must be controlled by licensed amateurs. All amateur frequencies may be used by RACES stations, except in times of declared emergencies, and tactical callsigns will be abolished. RACES repeater operation will use the WC-R bloc of calls.

Club station applicants no longer have to supply a copy of the club constitution and bylaws, but the FCC has announced that a club must, to be licensed, have at least two members (one licensed), a name, constitution, and amateur radio as its primary purpose.

The trial program of using the Civil Service system to administer amateur examinations has ended; the commission has decided to retain that function except in outlying areas where a field office is very distant. The program did not receive as much interest as anticipated.

More deregulation: The word "intracommunity" has been struck from the FCC's definition of a repeater station, in keeping with the permissibility of multiple repeater links. "DX" repeaters are now not in keeping with the spirit of the rules.

Ten meter repeaters are now beginning to appear; WR1AAA in Malden MA had the first reported ten meter system, operational in February. Now if only there were sunspots . . .

License guide publishers were up in arms when the ARRL sent a letter to advertisers implying that their forthcoming Novice text would be recognized by the FCC as the only official text, and that passing a course administered by an ARRL club would be the primary route to a Novice license in the future. In fact, the FCC has not given the ARRL any special status, and is contemplating letting local clubs certify Novice class graduates, to lessen the test grading load at Gettysburg. Details remain to be worked out.

27 MHz CB expansion had been tentatively scheduled for announcement around April Fools' Day, but was put off for perhaps a year at the last minute. It seems that the proposed new channels were 455 kHz away from existing channels, and i-f frequency intermod would have caused interference to other services. New frequencies are still being sought somewhere in the spectrum.

The FCC has waived the rules to permit ATV repeaters to operate in the 420 MHz band outside of normal repeater allocations, for a one year period ending next March. WR4AAG near Washington DC had been operating with 439 MHz input, 427 MHz output for some time with temporary authorization; future ATV repeaters will probably be covered by a coordination plan that has yet to be worked out.

The HIRAN docket to permit offshore nongovernmental radiolocation services to share the 450 MHz ham band has been acted upon; such services will be permitted on a case-by-case basis. Amateurs had expressed dissatisfaction with the idea, but few complaints of interference arose from previously authorized stations. Amateurs are expected to scream like mad if they receive interference, as they have priority there.

In the Matter of

Deregulation of Subpart F, Radio Amateur Civil Emergency Service (RACES), in Part 97

Docket No. 19723

RM-968, RM-1116, RM-1478, RM-2032, RM-2154, RM-2168

REPORT AND ORDER
(PROCEEDING TERMINATED)
Adopted: February 11, 1976;
Released: February 19, 1976

By the Commission: Commissioner Reid concurring and issuing a statement in which Chairman Wiley and Commissioner Hooks join.

1. On April 18, 1973 the Commission adopted a Notice of Inquiry in Docket 19723, FCC 73-40, which was published in the Federal Register on April 27, 1973, 38 F.R. 10467 (1973). In adopting the Notice of Inquiry the Commission sought comments on several matters fundamental to the future structure and organization of the Radio Amateur Civil Emergency Service (RACES). We particularly wished to receive from informed parties comments concerning the effectiveness of the present RACES program, the type of RACES program, if any, that should be continued, the objectives RACES should attempt to achieve, and the way in which RACES should be structured to achieve those objectives.

2. The Commission received some one hundred thirty comments in response to its Notice of Inquiry, and on June 12, 1974 we adopted a Notice of Proposed Rulemaking in this proceeding, FCC 74-609, which was published in the Federal Register on June 24, 1974, 39 F.R. 22282 (1974). Comments were invited from interested parties and were due on or before September 25, 1974. Reply comments were due on or before October 10, 1974.

3. In our Notice of Proposed Rulemaking we proposed to simplify greatly those sections of Part 97 concerning RACES by:

(a) Making all licensed amateur radio operators and stations eligible for participation in RACES, provided such operators and stations are registered with and enrolled in a civil defense organization;

(b) Discontinuing present requirements for RACES Communications Plans, FCC Certifications and Authorizations (FCC Forms 481 and 482);

(c) Permitting RACES station licenses to be issued directly to civil defense organizations;

(d) Providing, except during emergencies, for the shared use of amateur frequencies between amateur and RACES stations on a first-come-first-served basis;

(e) Requiring control operators of RACES stations to be licensed amateur radio operators and making operator privileges in RACES identical to those held in the Amateur Radio Service;

(f) Limiting useage of RACES stations to bona fide civil defense emergencies and up to one hour per week of drills and tests;

(g) Abolishing tactical or secret call signs, currently authorized by Section 97.213 of the Rules, assigning the same distinctive two letter call sign prefix to all RACES stations to facilitate their identification as RACES stations, and requiring all other amateur stations participating in RACES to use their regular assigned call signs when participating in RACES/civil defense activities;

(h) Limiting permissible communications of RACES stations and amateur stations operating in RACES to communications with RACES stations, amateur stations participating in RACES, and those other stations listed in proposed Section 97.189.

4. We received comments representing the views of approximately one hundred fifty individuals and organizations in response to our Notice of Proposed Rulemaking in this proceeding. Our respondents included the Secretary of Defense, fifteen state civil defense agencies, forty municipal or county civil defense organizations, and sixteen amateur clubs and organizations, among them the American Radio Relay League (ARRL). All comments received have been carefully analyzed by the Commission's staff, and we are now prepared to undertake final action in this Docket.

5. Comments on the broad contours of our proposal ranged from several expressing the opinion that RACES has become little more than an extension of local government used by elected officials when normal radio frequencies are busy, and which should therefore be removed from the amateur service entirely, to others viewing strict local government control of RACES to be absolutely essential and requesting more, rather than less, Commission regulation of RACES.

6. Comments received on the proposed amendments were generally favorable. Typical was the response of the Secretary of Defense, who characterized the proposal as an "admirable step towards simplifying the unduly complex RACES licensing procedures." Similarly, the ARRL agreed "in principle with the modifications to the RACES rules proposed by the Commission . . ."

7. While several comments cited the absence of either RACES organization or activity in the respondents' areas as evidence justifying total elimination of RACES everywhere, others indicated RACES to be precisely the sort of highly organized and effective means of emergency communications so vital in times of man-made and natural disasters.

8. Accordingly, we reaffirm those findings outlined in our Notice of Proposed Rulemaking in this proceeding, namely, that there does exist today a definite need in some areas for the type of service RACES is intended to provide, and that such a communications network should at least be available to those communities desiring it. In this Report and Order, therefore, we are adopting the amendments contained in our Notice of Proposed Rulemaking essentially as proposed and as set forth in the Appendix hereto.

9. Although we are adopting the amendments to Part 97 generally as proposed, several questions concerning specific sections of the Docket merit separate discussion.

10. That section of the proposed amendments making all licensed amateur radio operators, regardless of license class, eligible for participation in RACES was almost universally accepted. Recent trends, such as the burgeoning number of repeaters available for amateur use, have amply demonstrated the utility of the VHF bands in providing dependable communications. A large segment of the VHF user population consists of Technician Class licensees, and since these licensees have proven themselves in the past to be highly qualified communicators, we perceive no reason for denying such a resource to those RACES organizations desiring to utilize it.

11. Our proposal to eliminate present requirements for RACES Communications Plans, FCC Certifications and Authorizations (FCC Forms 481 and 482) met with general approval, and we believe such deletion to be consonant with recent Commission attempts to simplify and deregulate the Amateur Radio Service. Thus, filing of FCC Forms 481 and 482 will no longer be required to obtain RACES authorization. We appreciate the position of those governmental entities such as the State of California expressing both concern over elimination of these requirements and fear that lack of provision for formal communications plans and frequency coordination will create confusion and limit the usefulness of RACES. We believe, on the contrary, that because RACES is at its base an amateur service, a service traditionally characterized by voluntary cooperation between groups and individuals, such apprehension is not warranted. Those civil defense organizations wishing to do so may of course establish communications plans and coordinate frequencies as extensively as they wish. In the future, however, such planning will be a matter for civil defense authorities and amateurs, not the Commission.

12. The proposals permitting RACES station licenses to be issued directly to civil defense organizations and providing for the shared use of all amateur frequencies between amateur and RACES stations on a first-come-first-served basis encountered relatively little opposition. Those respondents critical of the proposed amendments contended, in substance, that to permit use of amateur frequencies by amateurs and RACES groups would make effective civil defense emergency frequency planning difficult. The primary fear appears to be that unless specific frequencies are assigned for exclusive RACES use, interference from amateurs may be sufficient to render RACES communications impossible. We note, however, that the Commission may in the future, as now, designate frequencies for RACES use in the event of emergency under the provisions of Section 97.107 of the Rules, and would observe, further, that amateurs have a long tradition of voluntary cooperation in emergency situations, a tradition we have every reason to believe will continue in the future. We conclude, therefore, that their exists no real basis for concern in this regard.

13. Our proposal to require control operators of RACES stations to be licensed amateurs proved to be somewhat controversial. Many respondents, particularly those representing governmental and RACES organizations, expressed the belief that in requiring RACES operators to be in all cases licensed amateurs we would be severely limiting RACES' usefulness. A commonly articulated concern was that in many areas of the country, especially rural areas, there are few amateur licensees, and that for RACES to be a functional service it may in some instances be essential for local RACES officers to recruit as RACES operators personnel holding Commission commercial licenses, a practice currently authorized by Section 97.203 of the Rules. Several of our respondents also attempted to justify operation by commercial licensees on amateur frequencies by noting that some RACES stations are manned twenty-four hours per day and that volunteer amateurs may be unwilling to serve on an around the clock basis. Further, a few comments stated that because many disasters strike with great swiftness, effective use of RACES stations virtually dictates use of commercial operators, at least until amateur operators are available to man the stations. As outlined by the Secretary of Defense, commercial licensees are necessary in such situations to "provide the official direction and supervision needed in the case of an emergency . . . [to] fill the interstices caused by the inability of amateurs to provide sufficient communications support in a given area." Assuming, without deciding, these arguments to be valid, we nonetheless believe

they ignore the fundamental principle inherent in RACES, namely, that it is an amateur service. The proposition that there can be any circumstances whatsoever in which commercial operators may operate on amateur frequencies is contrary to the definition of the service found in Section 97.3 of the Rules and is conceptually unacceptable. We believe that if RACES cannot function without commercial operators, it should probably be removed from Amateur Radio Service frequencies entirely.

14. Much of what was said in the preceding paragraph applies with equal force to the problem of the scope of operating privileges to be extended amateur operators participating in RACES. Consistent with our desire to make RACES an integral part of the amateur service, we are herein adopting Section 97.179 as proposed and making operator privileges in RACES identical to those held in the amateur service. While we anticipate that some RACES organizations will be inconvenienced in ensuring their operators utilize only those frequencies available under the terms of their licenses, we believe any such inconvenience will be far outweighed by the benefits to be realized in making RACES an integral part of the Amateur Radio Service.

15. Much concern was also expressed over limiting useage of stations participating in RACES to bona fide civil defense emergencies and a maximum of one hour per week of drills and tests, as proposed in Section 97.191. Such a limitation on drills, some contended, is unrealistic because it often takes longer than one hour simply to call the roll and attend to other administrative matters on a RACES network. We are not persuaded by such arguments. While some of the larger RACES networks may be forced to adopt more efficient methods of operation to comply with the new time limitation, we believe most RACES operations will not be seriously affected. Those amateurs wishing to sharpen their network traffic handling skills beyond that they are able to acquire as RACES participants may of course do so through those amateur networks organized for this purpose.

16. Our proposal to eliminate tactical call signs, assign distinctive call signs to RACES stations, and require amateur stations participating in RACES to use their amateur call signs was criticized by several of the larger civil defense organizations. These respondents stated, in substance, that such a change in standard RACES operating procedure would engender confusion, cause unnecessary delay, and make network operation generally less efficient. We believe, however, that operation on amateur frequencies should whenever possible conform to accepted amateur practice, and that by requiring the use of amateur call signs on RACES networks we are taking an appropriate step in that direction. New RACES stations or those renewing their licenses after the effective date of these amendments will be assigned call signs with a prefix of "WC" followed by the appropriate amateur call sign district indicator and three letters. RACES repeater stations will be assigned call sign suffixes beginning with "R".

17. Several comments alleged that limiting permissible communications of RACES stations and amateur stations participating in RACES to communications with RACES stations and those other stations listed in proposed Section 97.189 would reduce RACES network effectiveness in time of emergency. A few respondents suggested that non-RACES amateurs may be in positions to render valuable assistance to RACES operations in emergency situations, and that, in any event, in light of the proposed amendment discussed in the preceding paragraph, requiring amateur stations participating in RACES to use their amateur call signs, such a prohibition would be unenforceable. While conceding the obvious difficulties involved in enforcing Section 97.189 as proposed, we note the long self-policing history of the Amateur Service and conclude that enforcement will not constitute a serious problem. At the root of proposed Section 97.189 is the notion that RACES is a discrete system within the Amateur Service, designed to provide specific types of communications in narrowly defined situations. We believe, therefore, that only these stations registered in RACES should be permitted to communicate with RACES stations, and *vice versa*. We would observe, however, that there is nothing to prevent amateur stations registered in RACES from taking part in other organized and unorganized amateur activities and communicating with non-RACES amateur stations in those contexts.

18. Some comments raised questions concerning the definition of "RACES station" in proposed Section 97.163(b). They asked whether the language "specific land location" meant such a station could be operated as a portable station. The answer is "yes": a RACES station may be operated portable in the same fashion as any other amateur station. We merely require that the licensed station location be a "specific land location."

19. Finally, we would note that because all amateur frequencies are now available for RACES use, repeater stations operating in RACES may now make full use of those frequencies allocated for repeater useage in the Amateur Service. The limitations of proposed Section 97.185 apply only in those emergencies requiring invocation of the President's War Emergency Powers under Section 606 of the Communications Act of 1934, as amended.

20. In view of the foregoing, we believe these amendments of Part 97 of the Rules to be in the public interest, convenience, and necessity.

21. Authority for the rule changes adopted herein is contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended.

22. These amendments shall become effective upon the date specified in paragraph 23. In order to avoid undue hardship, existing RACES stations may continue to operate under their current authorizations and the existing Rules until the expiration date of their licenses. If the expiration date of an existing RACES station license is less than one year and six months from the effective date of these amendments, it may be renewed upon proper application for a period of one year, during which time the existing rules shall continue to apply. All other new and renewed RACES licensees shall comply with the rules as amended. Each new RACES station application shall be submitted on an FCC Form 610-B, with an indication it is a RACES station application.

23. Accordingly, IT IS ORDERED that Part 97 of the Commission's Rules IS AMENDED as shown in the Appendix attached hereto effective March 23, 1976. IT IS FURTHER ORDERED that this proceeding is TERMINATED.

FEDERAL COMMUNICATIONS COMMISSION*
Vincent J. Mullins
Secretary

*See attached Concurring Statement of Commissioner Reid in which Chairman Wiley and Commissioner Hooks join.

NOTE: Rules changes herein will be covered by T.S. VI(75)-3.

APPENDIX

Part 97 of Chapter 1 of Title 47 of the Code of Federal Regulations is amended in its entirety as follows:

SUBPART F – RADIO AMATEUR CIVIL EMERGENCY SERVICE (RACES)

General

§97.161 Basis and purpose.

The Radio Amateur Civil Emergency Service provides for amateur radio operation for civil defense communications purposes only, during periods of local, regional or national civil emergencies, including any emergency which may necessitate invoking of the President's War Emergency Powers under the provisions of §606 of the Communications Act of 1934, as amended.

§97.163 Definitions.

For the purposes of this Subpart, the following definitions are applicable:

(a) *Radio Amateur Civil Emergency Service.* A radiocommunication service conducted by volunteer licensed amateur radio operators, for providing emergency radiocommunications to local, regional, or state civil defense organizations.

(b) *RACES station.* An amateur radio station licensed to a civil defense organization, at a specific land location, for the purpose of providing the facilities for amateur radio operators to conduct amateur radiocommunications in the Radio Amateur Civil Emergency Service.

§97.165 Applicability of rules.

In all cases not specifically covered by the provisions contained in this Subpart, amateur radio stations and RACES stations shall be governed by the provisions of the rules governing amateur radio stations and operators (Subparts A through E of this part).

Station Authorizations

§97.169 Station license required.

No transmitting station shall be operated in the Radio Amateur Civil Emergency Service unless:

(a) The station is licensed as a RACES station by the Federal Communications Commission, or

(b) The station is an amateur radio station licensed by the Federal Communications Commission, and is certified by the responsible civil defense organization as registered with that organization.

§97.171 Eligibility for RACES station license.

A RACES station will only be licensed to a local, regional, or state civil defense organization.

§97.173 Application for RACES station license.

(a) Each application for a RACES station license shall be made on the FCC Form 610-B.

(b) The application shall be signed by the civil defense official responsible for the coordination of all civil defense activities in the area concerned.

(c) The application shall be countersigned by the responsible official for the governmental entity served by the civil defense organization.

(d) If the application is for a RACES station to be in any special manner covered by §97.41, those showings specified for non-RACES stations shall also be submitted.

§97.175 Amateur radio station registration in civil defense organization.

No amateur radio station shall be operated in the Radio Amateur Civil Emergency Service unless it is certified as registered in a civil defense organization by that organization.

Operating requirements

§97.177 Operator requirements.

No person shall be the control operator of a RACES station, or shall be the control operator of an amateur radio station conducting communications in the Radio Amateur Civil Emergency Service unless that person holds a valid amateur radio operator

license and is certified as enrolled in a civil defense organization by that organization.

§97.179 Operator privileges.

Operator privileges in the Radio Amateur Civil Emergency Service are dependent upon, and identical to, those for the class of operator license held in the Amateur Radio Service.

§97.181 Availability of RACES station license and operator licenses.

(a) The original license of each RACES station, or a photocopy thereof, shall be attached to each transmitter of such station, and at each control point of such station. Whenever a photocopy of the RACES station license is utilized in compliance with this requirement, the original station license shall be available for inspection by any authorized Government official at all times while the station is being operated and at other times upon request made by an authorized representative of the Commission, except when such license had been filed with application for modification or renewal thereof, or has been mutilated, lost, or destroyed, and request has been made for a duplicate license in accordance with §97.57.

(b) In addition to the operator license availability requirements of §97.83, a photocopy of the control operator's amateur radio operator license shall be posted at a conspicuous place at the control point for the RACES station.

Technical requirements

§97.185 Frequencies available.

(a) All of the authorized frequencies and emissions allocated to the Amateur Radio Service are also available to the Radio Amateur Civil Emergency Service on a shared basis.

(b) In the event of any emergency which necessitates the invoking of the President's War Emergency Powers under the provisions of §606 of the Communications Act of 1934, as amended, unless modified or otherwise directed, RACES stations and amateur radio stations participating in RACES will be limited in operation to the following:

Frequency or Frequency Bands	Limitations
kHz	
1800-1825	1
1975-2000	1
3515-3550	2, 4
3984-4000	
3997	3
7097-7103	4
7103-7125	2, 4
7245-7255	2, 4
14047-14053	4
14220-14230	2, 4
21047-21053	4
MHz	
28.55-28.75	
29.45-29.65	
50.35-50.75	
53.30	3
53.35-53.75	
145.17-145.71	
146.79-147.33	
220-225	5

(c) Limitations:

(1) Use of frequencies in the band 1800-2000 kHz is subject to the priority of the Loran system of radionavigation in this band and to the geographical, frequency, emission, and power limitations contained in §97.61 of the rules governing amateur radio stations and operators (Subparts A through E of this part).

(2) The availability of the frequency bands 3515-3550 kHz, 7103-7125 kHz, 7245-7247 kHz, 7253-7255 kHz, 14220-14222 kHz, and 14228-14230 kHz for use during periods of actual civil defense emergency is limited to the initial 30 days of such emergency, unless otherwise ordered by the Commission.

(3) For use in emergency areas when required to make initial contact with military units; also, for communications with military stations on matters requiring coordination.

(4) For use by all authorized stations only in the continental United States, except that the bands 7245-7255 kHz and 14220-14230 kHz are also available in Alaska, Hawaii, Puerto Rico, and the Virgin Islands.

(5) Those stations operating in the band 220-225 MHz shall not cause harmful interference to the government radiolocation service.

§97.189 Points of communications.

(a) RACES stations may only be used to communicate with:

(1) Other RACES stations;

(2) Amateur radio stations certified as being registered with a civil defense organization, by that organization;

(3) Stations in the Disaster Communications Service;

(4) Stations of the United States Government authorized by the responsible agency to exchange communications with RACES stations;

(5) Any other station in any other service regulated by the Federal Communications Commission, whenever such station is authorized by the Commission to exchange communications with stations in the Radio Amateur Civil Emergency Service.

(b) Amateur radio stations registered with a civil defense organization may only be used to communicate with:

(1) RACES stations licensed to the civil defense organization with which the amateur radio station is registered;

(2) Any of the following stations upon authorization of the responsible civil defense official for the organization in which the amateur radio station is registered:

(i) Any RACES station licensed to other civil defense organizations;

(ii) Amateur radio stations registered with the same or another civil defense organization;

(iii) Stations in the Disaster Communications Service;

(iv) Stations of the United States Government authorized by the responsible agency to exchange communications with RACES stations;

(v) Any other station in any other service regulated by the Federal Communications Commission, whenever such station is authorized by the Commission to exchange communications with stations in the Radio Amateur Civil Emergency Service.

§97.191 Permissible communications.

All communications in the Radio Amateur Civil Emergency Service must be specifically authorized by the civil defense organization for the area served. Stations in this service may transmit only civil defense communications of the following types:

(a) Communications concerning impending or actual conditions jeopardizing the public safety, or affecting the national defense or security during periods of local, regional, or national civil emergencies:

(1) Communications directly concerning the immediate safety of life or individuals, the immediate protection of property, maintenance of law and order, alleviation of human suffering and need, and the combating of armed attack or sabotage;

(2) Communications directly concerning the accumulation and dissemination of public information or instructions to the civilian population essential to the activities of the civil defense organization or other authorized governmental or relief agencies.

(b) Communications for training drills and tests necessary to ensure the establishment and maintenance of orderly and efficient operation of the Radio Amateur Civil Emergency Service as ordered by the responsible civil defense organization served. Such tests and drills may not exceed a total time of one hour per week.

(c) Brief one way transmissions for the testing and adjustment of equipment.

§97.193 Limitations on the use of RACES stations.

(a) No station in the Radio Amateur Civil Emergency Service shall be used to transmit or to receive messages for hire, nor for communications for material compensation, direct or indirect, paid or promised.

(b) All messages which are transmitted in connection with drills or tests shall be clearly identified as such by use of the words "drill" or "test", as appropriate, in the body of the messages.

CONCURRING STATEMENT OF COMMISSIONER CHARLOTTE T. REID (CHAIRMAN RICHARD E. WILEY AND COMMISSIONER BENJAMIN L. HOOKS JOIN) RE: RACES

I have concurred with my colleagues in this decision because I believe RACES remains a viable means of communications. RACES can and has filled a communications void in times of emergencies and I feel it should be administered and operated primarily by licensed amateurs. However, I do feel there will be bona fide emergencies where licensed amateurs may not be available and, in such cases, commercial operators should be allowed to operate the RACES stations until the licensed amateurs arrive on the scene. I would have preferred an exception to the licensed amateur operator rule with a restriction that such use could be only in time of an extreme emergency, not routine police, fire or ambulance activity.

PUBLIC NOTICE
WAIVER TO PERMIT AMATEUR TV REPEATERS

March 1, 1976-S

The Commission, by Chief, Safety and Special Radio Services Bureau, has waived Section 97.61(c) of the Commission's Rules for a period of 1 year to permit operation of fast-scan amateur television repeater stations outside of the sub-bands normally reserved for repeater operations in the 450 MHz amateur band.

On January 25, 1974, the Commission issued a six month Special Temporary Authorization which waived Section 97.61(c) of the Rules governing the Amateur Radio Service to permit operation of fast-scan television repeater station WR4AAG in the 450 MHz band. The station is used to retransmit television signals of other amateur television stations throughout the Washington, D.C., area, for the purpose of gathering experimental data concerning the feasibility of fast-scan television repeater operations at 450 MHz. The Special Temporary Authority waiving Section 97.61(c) was renewed several times subsequent to its issuance, with the most recent renewal set to expire on March 3, 1976. A petition for rulemaking to allow regular operation of this station, RM-2507, was filed on January 16, 1975. The Commission now has that petition under consideration, as well as several other requests of a similar nature. Pending formal consideration of these petitions, and pending implementation of a formal frequency coordinating mechanism within the Amateur Radio Service which would oversee the frequency selections of all repeater stations, the Commission is waiving Rule Section 97.61(c) for a period of 1 year to permit continued experimentation in this mode of operation. Any licensed amateur repeater station operating in the 450 MHz band may conduct such tests without prior Commission approval. This waiver is effective February 27, 1976. Authority for this waiver is contained in Section 0.331 of the Commission's Rules.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

THE GOOD THE BAD THE UGLY

What with the Fourth of July, the bicentennial and other red, white and blue stimuli, I'm given to paying some attention to the number of bicentennial callsigns I'm not hearing on the bands. Tsk.

Yes, I know all about the bad aspects of our country . . . the incredibly awful conditions, seemingly without solution, in parts of New York City . . . the IRS . . . the prison system (if the word "system" is adequate) . . . the inability of our schools to teach . . . there are many outrages and frustrations and, unless you have a way to put things into perspective, they can bring you down. Our news media are certainly no help, with their dwelling on death and destruction to cater to our morbid fascination with these things.

For all the problems we have in this country, where else would you rather live? If you are very much traveled you have reached the same conclusion I have . . . for all its problems, the U.S. is by far the best. I think I liked it a bit better when I was young and when we had only about half as many people . . . and cities were about one fourth their present size . . . and hot dogs were a nickel. The dreams of youth.

But a country is not its geography – it is its *people* and we have *great* people. Yes, I know, we have some rotten people, too . . . I moved to New Hampshire from New York City, didn't I? We have a sprinkling of sour people around us . . . even on our ham bands . . . but we try to avoid them as much as we can. The general impression you get in listening to the amateur bands is one of friendliness and good cheer . . . heck, we even hear that attitude on CB these days, just to show how things can change.

My message is this: Resist the outrages and back the good things. Use your bicentennial callsign proudly . . . we have a great country and we can make it a lot better if we join those working towards improving it and resist those trying to tear it down.

When you see the courts refusing to acknowledge the Constitution, raise hell. When Ma Bell grinds some poor bastard into the dust just because he can't afford to fight . . . raise hell. We can cure many of the outrages we now accept with a shrug . . . and thank heavens they happened to someone else and not us . . . if we stop looking around for someone else to stand up and say NO! If something needs stopping, get busy and see what you can do about it . . . get some friends to help . . . write letters to the newspapers, television stations . . . picket . . . arrange a media event . . . write your congressman . . . raise hell and put a brick under it. Be a troublemaker and be damned proud of it.

Our country was not started by sheep . . . those men were troublemakers . . . and look what they've done! Note that they were constructive troublemakers, not fanatics . . . we don't have to tear things down to make them better – we have to build and improve them. Bombing Ma Bell won't make for better or cheaper service . . . letters to Congress about Bell outrages will . . . etc.

A lot of people put me down because I speak out . . . I'm called a radical . . . but I often wonder how far to the right people must be who see me as radical! I'm accused of tilting at windmills . . . and I smile at that because it does prove that I am at least trying to get something positive done while my critics are doing nothing but being destructive.

When people get power they have a strong tendency to abuse that power . . . and that holds for big business, for government officials and for labor leaders. I feel that the strength of our country lies in our ability to fight against powerful people bent on doing bad things. The most serious weakness we have is the ability of many (if not most) people to put up with these bad things and not raise hell about them.

The number of bad things happening is almost overwhelming at times. It would be most discouraging if we could not compare our situation with other countries . . . where we find that most have it a lot worse. Since our news media tend to stress disasters, we are not much in the habit of thinking in terms of the good things which are going on . . . pity, for though these things are not "news," they more than overshadow the miseries.

In amateur radio we have some bad guys and a whole lot of good guys. The good guys are organizing and running traffic nets, eyebank nets, emergency nets, DXpeditions, repeaters, clubs which are teaching new hams our hobby, hamfests . . . and they are experimenting with new techniques of RTTY, slow scan television, moonbounce, Oscar operating, computers, new antennas . . . etc. The bad guys are trying to louse up nets, spoil contacts with interference, make DX pileups a mess, organize repeater wars, keep AM alive on 75, jam RTTY or SSTV transmissions, etc.

You know what I do when I hear some ass proving he is one on the air? I go ahead and tell him what I think of him and the lousy things he is doing. Oh, this makes me some enemies, no doubt about that . . . but they are enemies I am proud of and point to with pride. I don't think you'll hear many bad guys claiming friendship with Wayne Green . . . nor many good guys giving me the bad mouth. I would not want as friends those enemies of whom I am aware.

So much for the soapbox this July . . . now, about those bicentennial callsigns. I want to hear all you good guys out there using them . . . proud of the best aspects of our country and the things we have accomplished. Let's look on those callsigns as advertisements for the United States . . . and as promises to do everything we can to make it better . . . to put ourselves on the line to fight as best we can the bad things . . . the arrogance of big business . . . of government. When something is wrong let's stamp our foot and try our very best to make it right. It is not easy to stick up for your rights . . . particularly when everyone else is shuffling around uneasily, trying to figure out how to avoid trouble.

Troublemakers started our country . . . and they will keep it strong. It is sometimes absolutely amazing what one troublemaker can do. One lone troublemaker managed to get parking meters outlawed for an entire state! Most of the time the entrenched power of government officials is tough to fight, but each has his weak points and you can find them. They either are appointed or elected, and this means you may be able to get in your licks at re-appointment time or re-election time . . . if all else fails.

The Watergate mess has weakened the power grip of many government agencies on us . . . the FBI, CIA, DIA, IRS, and such . . . but they will build it up again unless we keep the pressures on them. They got much of their power in order to help them fight organized crime; instead, they leveled the power at the less powerful . . . us, the unorganized citizens . . . and left the powerful organized crime

EDITORIAL BY WAYNE GREEN

from page 4

people alone. The results were devastating at times. With a few more troublemakers like those *Washington Post* reporters who blew the whistle on the whole rotten situation, our country will move ahead and get better, little by little.

WAYNE AT ATLANTA

Plans have been made for a one hour "*73* Forum" at the Atlanta HamFestival on Saturday, June 12th. In order to make candid questions and answers possible, I will ask that no recorders be used. There are a great many things going on in and around amateur radio that are being kept a secret from most amateurs, and one of the major reasons why I am prohibited from speaking at most ARRL conventions is that I tell it like it is. Note that the Denver ARRL Convention was forced to cancel my invitation to speak this year because of fear of what I might reveal.

What effect will the current craze for CB have on amateur radio? And what will be the impact of microcomputers on amateur radio? I'll try to put these into perspective for you. In addition, please bring all of the Wayne Green haters you can to the forum and have them ask me about the things they object to that they think I've done. I won't object to some Wayne Green fans, if any can be found on this short notice, just so I won't feel like I'm all alone. If you are not pro or con Wayne Green, please go somewhere else . . . I want to talk with people who at least *care* about amateur radio and if my editorials haven't gotten you either enthused or furious you are so deeply apathetic that you are beyond my help.

AMELIA

My *TV Guide* reveals that Hollywood is working on a three hour TV movie about Amelia Earhart for next season. Since she has been mentioned in the Ancient Aviator, this is timely.

Some years ago, when the book on Amelia came out, I mentioned the curious set of coincidences which enabled me to have heard much of what the book's author spent years trying to find out. For instance, the chap who set up Amelia's plane with the special engine and fuel tanks so that she could take pictures of Truk for our government was a good friend of my father's and I heard about the project shortly after her disappearance.

Truk was a major Japanese naval base at the time and the U.S. wanted desperately to know what was going on there. The whole 'round the world flight of Amelia's was a cover for the one leg where she would zig up and fly over Truk, taking pictures, and then get back on her published route again as if nothing had happened. In order to cover the extra miles involved without losing too much time, she needed a more powerful engine and extra wing tanks.

She apparently made it over Truk okay, but got lost trying to find Howland Island and ended up at Majuro in the Marshall Islands, according to the book. I made two one month rest stops at Majuro between submarine war patrols during WWII, and heard word there of her landing, visit and eventual pickup by the Japanese. They claimed she and the chap with her, who was hurt in the crash, were taken to Saipan.

When I visited Saipan a few patrol runs later, Amelia was mentioned again and the story was that both she and Fred Noonan had died and been buried there. The author of the book came up with the same story, but he had a hard job getting it. Apparently a lot of people are still trying to cover up the Truk overflight. Weird.

You may be sure I'll be interested in seeing the movie on television when they show it later this year.

73 GETS BEST AUTHORS

Several readers have asked why it is that *73* seems to always get the best articles. The answer is not complicated . . . just put yourself in the shoes of an author who has put a lot of work into a project and has written it up for publication.

You want two major things from your article . . . first, you want to reach the largest possible readership . . . hopefully with a good percentage interested in building. Secondly, you want to be reasonably paid for your effort . . . it's only fair.

That sort of narrows the choice down to one magazine . . . *73*. *QST*, the *only* other ham magazine with a substantial readership, doesn't pay for articles . . . and doesn't have all that much readership interested in home building. *QST* reflects the interests of its readers and is only third in the number of construction projects.

While prestige is not always of paramount importance, it is a nice plus . . . and being published in the largest ham magazine is a feather in anyone's cap. It doesn't hurt at all when job hunting is in season to have a few articles you can point to.

Unfortunately, it is getting more and more difficult to have an article accepted for publication in *73* . . . you can see more and more of our rejected articles in the other ham magazines. We don't always get first pick, but most of the time we do. Right now we have a big need for microprocessor-oriented material and digital construction projects. We're always interested in state of the art techniques and new products articles. What have you?

EXAMS WANTED

It has been over a year since we've gathered a set of the FCC exams and we would like to update our collection. This helps us make sure that our license study guides are in every way up to date. Since the FCC can't send out copies of the tests, we have to depend upon readers. It is a bit of a bother, so we'll offer $5 for each different test copy we receive. Novice and Tech exams are the easiest to get, followed by the conditional exams. Since the conditional tests are a bit more difficult than those given at FCC offices, they will be particularly helpful. Let me clarify that offer . . . $5 for each exam that is different for us. We will keep the exams confidential . . . they will be used just for checking study material.

AMATEURS TEST EMERGENCY LOCATING SYSTEM

A test was run recently via Oscar 7 to determine the feasibility of using a satellite repeater for emergency locating of lost people. The test, using a low powered transmitter (under one Watt), indicated that the system was quite workable, and a rough location of the transmitter was determined by processing the Doppler shift of the signal. The test gave the location of the emergency transmitter within about 7 miles. With a little experience, the system could be made to work using transmitter powers of about 100 milliwatts, and locations within two to four miles are expected.

Think of the ramifications of this work! A tiny transmitter about the size of a matchbox could give us the approximate location of any lost person anywhere in the world . . . at sea drifting, in the desert, or perhaps in the mountains. How long before a channel is set up for this service? And then how long before the matchbox rigs are available . . . probably with one chip and a battery. A few more tests will indicate how much antenna is needed . . . a simple whip may do, but it is more likely that one of those small umbrella dish reflectors will give the amplication needed.

Amateur radio again is in the forefront of important technical developments in communications.

PHONE CALLS

Phone calls to *73* . . . please try not to. As bad as the mail is, try to use what is left of the postal service. On subs and address changes please hold tight for at least six weeks before getting nervous . . . our computer is still over 50 miles away and it takes ages to make changes or find out what is happening. Dotty is here to help from about 9-4 Eastern time weekdays. Please do not call except during our business hours . . . and leave us alone on weekends except in the case of really serious emergencies. We are not very friendly to the chap who calls from California at midnight Saturday and explains that, gee, it is only 9 o'clock out there. If you must call – (603) 924-3873.

Dennis O'Brien WB6CBJ/5 uses his new IC-202 portable, establishing a Corpus Christi first by operating "elephant mobile." Dennis, a native of California, is presently in flight training at the Corpus Christi Naval Air Station.

Tornado Alert

Radio and television programs are cut short by a special tornado watch bulletin issued by the National Weather Service at Dress Regional Airport.

At his home on Seib Road near Daylight, Hal Wilson moves away from the television to a radio which he and about 120 other members of Tri-State Emergency Net (network) are licensed to operate.

Several members activate radios in their homes and begin talking to one another. The instructions are clear. The amateur radio operators head outside to observe weather conditions and watch for a funnel cloud.

"I've sat up until midnight, 1, 2 in the morning with the fellas trying to sight a storm," says Wilson, an administrative supervisor with Keller Crescent Co. in Evansville.

When a funnel cloud is sighted by one of the radio operators, they use a private number to notify weather service officials immediately. In turn, the weathermen can verify a funnel cloud report by contacting one of the radio operators.

The radio operators are part of a larger group of residents in the Tri-State who volunteer their time as "spotters" for the weather service.

The procedure for sighting funnel clouds and alerting the public has become more sophisticated with the use of licensed radios, weather radar, special high frequency VHF M commercial radio weather stations which broadcast at 162.55 megahertz and switch on automatically with a special signal, and satellites 22,500 miles above earth which take pictures of the earth's surface for weather evaluation.

But even with all the equipment which makes possible more accurate and timely warnings, people are still killed by tornadoes.

Last year alone, there were 917 tornadoes in the United States which claimed 59 lives, according to the National Oceanic and Atmospheric Administration. Indiana, which accounted for 23 of those tornadoes, had no tornado related deaths in 1975.

Roland Guy Loffredo, meteorologist-in-charge at the National Weather Service here, points out that Indiana, Kentucky and Illinois are nearing the period — April and May — when maximum tornado activity has traditionally occurred.

Loffredo says the idea of a "tornado season" is a myth, because tornadoes can occur anytime warm, moist tropical air from the Gulf of Mexico clashes with cold, dry air moving down from Canada.

Typically though, those weather systems clash as seasons change when the earth shifts on its axis and the sun moves from the southeast toward the northwest. For example, Loffredo says that in the very early part of the year the greatest chance of tornadoes is in Florida. By April and May, the chance of tornadoes is great in the Tri-State and by June, areas of Northern Indiana, Northern Illinois and Wisconsin traditionally face the greatest risk of tornadoes.

Tornadoes average about 5 to 10 minutes on the ground. Most leave a path no more than an eighth of a mile wide by two to five miles long. Forward speed averages about 30 miles an hour, but may reach as much as 70 miles an hour.

"As a concentrated force," Loffredo describes tornadoes as the "most powerful of storms." Some of the worst tornadoes occurred on Palm Sunday, 1965, when about 50 twisters slammed into five states, including Indiana, and killed 256 Midwesterners. In 1925, a single tornado tore through parts of Missouri, Illinois and Indiana killing 689 persons.

In recent years, many lives have been spared due at least in part to an improved reporting system.

Weather officials say one of the most destructive tornadoes of all time hit Omaha, Neb., last May 6. More than 2000 homes were damaged or destroyed and property damage was estimated in the hundreds of millions of dollars.

Despite the vast amount of damage, there were only three deaths, and an Omaha newspaper headlined a story: "It could have been worse; but tornado alert worked."

HAM HELP

Please add me to your list for help with obtaining my license. I will need help in Germany as I will be arriving there on or about 10 July 1976. Telephone number will be Hldg Mil 7565.

Keep up the good work with the magazine, as I thoroughly enjoy reading each and every issue. As you can see from the enclosed request I am finally going to have to get a subscription.

SFC Edwen K. Gause
HQ, USAREUR & 7TH Army,
DCSOPS (FPD-FAB)
APO New York 09403

This note is to say what a fantastic magazine you and the staff put together, and ask for some Ham Help. *73* is responsible for my rebirth into ham radio after a Novice license expired in '66 due to the discovery of girls. After finding a copy of *73* at the local newsstand, I got off my duff and got another Novice, and am now heading for my General via *73's Study Guide* and code tapes — Ken Sessions' book makes theory crystal clear and easy to learn.

Now for the help. I've got a Harvey Wells R9A receiver with no manual or schematic . . . so if you can't tell me where I might find one, please run a Ham Help asking for a chance to buy or borrow one for copying.

Thanks for presenting an alternative viewpoint for the ham who isn't "League" oriented, and keep that great magazine rolling off the presses.

Greg Magarie WN1VIL
58 Wyman St.
Arlington MA 02174

Please include me as a Ham Helper for anyone who wants his Novice, Technician or General ticket.

Kevin C. Potter WA6DNW
646 Fairview Ave. Apt. 7
Arcadia CA 91006

Please add my name to your list of Ham Helpers.

I hold the amateur Extra, Restricted Radiotelephone Permit, C.A.P. ticket, C.B. license and am studying for the Commercial 2nd Class. I am Club Trustee and President. I work 20 meters CW about 95% of my time on the air. My equipment lets me operate on 80, 40, 20, 15, 10, 6, and 2 meters.

The Siouxland Amateur Radio Club meets every Wednesday night, 7:00-9:30 pm. We have 41 members, many of whom came from the CB bands when they found out how much more fun they could have with the amateur license. All will have passed the code test before you get this. Some members drive over 50 miles each way.

Our club is ready to help anyone who is really ready to study and not just expect it to be handed to them. We have found it takes from 3 to 7 weeks to get the code up to about 7 wpm, depending on how badly the license is wanted.

For any help or information, please contact me.

Amelia

When I put the cover on my typewriter last month, I had just returned from a 25 day swing around the country on an inspection tour of the more active airports. All but 3 of the 14 airports visited were city-owned; some were city-operated and some were leased to private operators. All had money problems, and nearly all had high tension wires on at least one approach to the field. I have a copy of my lightly padded expense account for the trip, which totaled $610. That included all transportation, meals, hotels, entertaining, etc. That was in 1929 when waiters, no matter how insulting they might be, would only get a 10% tip.

Now I had to get down to the business of changing a small flying field into an airport. The Ludingtons had already engaged the Airport Development and Construction Company of Philadelphia to do the engineering part of the job. My part was to tell A.D.C. what we wanted and where we wanted it, to keep a check on materials and workmanship, to approve designs and layouts, and to generally supervise the job. There was a small dirt floor hangar already on the field, with a lean-to which served as an office during the construction period.

There is nothing very exciting about building an airport, so I'll spare you the details. It took nearly a year to complete Central Airport, which included two hangars with lean-tos for shops and offices, a combination administration and station building, boundary lights, a beacon light tower, a BBT floodlight for night landings and two paved runways. In order to provide extra income, we built a public swimming pool and a miniature golf course, and leased a corner lot for a gas station.

When I got back from my survey trip around the country on February 8th, I learned that Bob Hewitt, General Manager and Chief Pilot of the Ludington Philadelphia Flying Service, had been critically injured in an automobile accident a few days before. So I made myself available to pinch hit for Bob on any flying jobs when they needed help. The Flying Service had quite a stable of airplanes: a clipped wing Waco 9, 3 Waco 10s with different engines, a Fairchild FC2, a Fairchild 71 and a Travelair 6000. Then, for fun, they had a Taperwing Waco. My flying for them included passenger hopping, testing, demonstrating and some cross-country trips (some more interesting than others).

Early in the morning of April 27, 1929, Bob Hewitt, who was still on crutches, phoned me and said that the Chamber of Commerce was *willing to pay* to have a plane fly down to Wilmington that morning to pick up Amelia Earhart and bring her back to Philadelphia for a reception and dinner in her honor. So I dashed out to the airport and found that they already had the new 6 passenger Fairchild 71 on the line and warmed up. Since it was my first flight in that type of plane, I took it around the field and landed it a couple of times before heading for DuPont's private field near Wilmington. I got Amelia to Philadelphia in plenty of time for her luncheon engagement. Next day (also on the Chamber of Commerce) I took her on an aerial tour of the "City of Brotherly Love."

Later in April, Brooks Parker, an insurance executive, wanted to fly a party down to the races at Havre de Grace, Md. One hitch was that he wanted to be set down on the track infield. It was early and there were very few people on the infield, the approach was good, only a low fence to get over, so we set down with plenty of room. Getting the field cleared off after the races for our trip home was a bit more of a problem.

On July 3, 1929, the Ludingtons started a summer weekend line from Central Airport to Cape Cod, departing Central Friday afternoon and arriving back Monday morning. The Fairchild 71 and Travelair 6000 were assigned to the run and four

Sanger Green and Amelia Earhart, Philadelphia Airport, April 4, 1929.

pilots (including myself) were provided with neat conservative uniforms. I had the honor of flying the first passengers in the Fairchild. Two of the passengers wanted to deplane at Jamestown (an island in Narragansett Bay across from Newport). The others were going to our terminal in a field on the Coonamessett Ranch near Falmouth. I never had even seen either place and my Jamestown passengers had no idea of where we could land, so after looking around a bit I set the ship down in a cemetery that had enough unobstructed room. We were not entirely welcome. Some of the people in the crowd that gathered were saying things about desecration and police, so I unloaded the passengers quickly and took off before Smokey could get there.

Although the line was supposed to be from Central to Cape Cod, there were usually variations. One time I had to find a place to land on Fisher's Island and several times I had to land at Martha's Vineyard or Nantucket (the latter two are islands just south of Cape Cod). There are a lot of deserted beaches on the south side of Martha's Vineyard, so when I had to go to Nantucket I would fly along them at treetop height and give my passengers a view of the "buff" bathers rushing to cover up. On one trip late in August I had to go to Nantucket with a stop at Newport. Headwinds had made me a trifle late, so by the time I left Nantucket alone for Falmouth it was getting real dusky. There were no lights on the field at Coonamessett, but Bob Hewitt, who had gone ahead of me in the Travelair, had a half dozen autos lined up at the approach to the field with their headlights shining down the field. Since I didn't have enough gas to take me to Boston, I had a "Hobson's choice" and came in over the parked cars as low and slow as I could. The lights didn't illuminate very much of the field so on touchdown I cut my ignition switch and stood on the brakes. I ended up about three feet from a big haystack.

The Coonamessett people really "did themselves proud" (as they say in New England). We had a small cottage, fully equipped, to ourselves. Our arrival night dinner always consisted of all the steamed clams and lobsters we could eat, with all the trimmings and a homemade desert. All our meals over the weekend were on the same scale. Regrettably this Cape Cod caper only lasted one season (1929). I guess the passengers were buying their transportation cheaper than the Ludingtons were.

Next month some happenings at Central Airport, air races, etc. Hope you have as much fun reading the column as I have writing it.

THIRTEEN HOURS AND THIRTY MINUTES

Firsts

In the Log of Amelia Earhart Putnam

1920	Learned to fly in California. Established Women's altitude record of 14,000 feet. (Kinner Airster)
June 17–18, 1928	***First*** woman to span the Atlantic in an airplane, flew as a passenger with Wilmer Stultz, pilot, and Louis Gordon, mechanic, from Trepassey Bay, Newfoundland, to Burry Port, Wales, 2,140 miles in 20 hours and 40 minutes. (Whirlwind-powered Fokker "Friendship").
September-October, 1928	***First*** woman to make round-trip solo transcontinental flight across United States. (Avro Avian)
March 28, 1929	Fourth woman to receive transport pilot license from Department of Commerce.
November 22, 1929	Established world speed record for women over a closed circuit course at Detroit with an average speed of 184.17 miles per hour. (Wasp-powered Lockheed Vega)
December 14, 1930	***First*** woman to fly an autogiro in the United States.
April 8, 1931	Established an altitude record of 18,415 feet for autogiros at Willow Grove, Pa. (Whirlwind-powerd Pitcairn)
May 28--June 22, 1931	***First*** to make a transcontinental flight across the United States in an autogiro. (Whirlwind-powered Pitcairn)
May 20-21, 1932	***First*** woman to fly an airplane solo across the Atlantic. ***First*** person to span the Atlantic twice by airplane in non-stop flight. Her time, 13 hours and 30 minutes for the 2,026 miles from Harbor Grace, Newfoundland, to Londonderry, Ireland, was the fastest for the Atlantic crossing and established a world's distance record for women. (Wasp-powered Lockheed Vega)

CONTESTS

ARRL STRAIGHT KEY NIGHT

Starts: 0100 GMT Saturday, July 3
Ends: 0700 GMT Sunday, July 4

Check *QST* for any changes in the rules!

Basically, rules require the use of a straight key only. Send "SKN" instead of "RST" during QSOs, to help identify contest stations. On 80-40-20 meters, try 060 to 080 kHz up from the bottom edge of the band. On Novice bands, try 10 kHz up from the bottom of the Novice band. After the contest period, send a list of calls of the stations contacted during the contest period, plus your vote for the best fist heard. Please mail entries as soon as possible to ARRL, 225 Main Street, Newington CT 06111.

QRP SUMMER CONTEST

Organized by the Activity Group-CW in Germany
Starts: 1500 GMT Saturday, July 3
Ends: 1500 GMT Sunday, July 4

A maximum of 15 hours' operation is allowed during the contest period, with the 9 hour pause taken in a maximum of 2 parts. General call is "CQ QRP." Maximum power for QRP stations is 9 Watts input.

EXCHANGE:

RST and QSO number/input. Add "x" if transmitter is CO or VXO controlled.

SCORING:

All QSOs are valid. Own country – 1 pt.; own continent = 2 pts., and DX = 3 pts. per QSO. Add an additional 3 points per QSO for a QSO with another QRP station. Handicap points (hcp) are given if either station is using below 3.5 Watts input or is xtal controlled, with a maximum of 4 hcps possible. Both stations multiply QSO points by 1 plus the hcps. Example: W2XX works G9XX, exchange 589 001/2x from W2XX, 579 100/4x from G9XX; both stations score 9 pts. for the QSO (3 pts. for DX x 3 hcps – both xtal, W2XX less than 3.5 Watts). Multipliers are 1 for each country in own continent and 2 for each DX country per band according to latest DXCC list (but call areas in JA, PY, VE, VK, W, and ZS count as separate countries). Final score is total QSO points times total multiplier.

QRO STATIONS:

Same rules, but input power is not limited. Use QRO and only QSO with QRP stations. Scoring is the same.

ENTRIES:

Send a "mini-log" by July 31st to: Hartmut Weber DJ7ST, D-3201 Holle, Kleine Ohe 5, Fed. Rep. of Germany.

CALENDAR

Jun 26 - 27*	ARRL Field Day
Jul 3	Straight Key Night
Jul 3 - 4	QRP Summer Contest
Jul 17 - 19	CW County Hunters Contest
Jul 24 - 25	ARRL Bicentennial Celebration
Aug 7 - 8	10-10 Net Summer QSO Party
Aug 14 - 15	European DX Contest – CW
Aug 21 - 22	SARTG Worldwide RTTY Contest
Aug 21 - 23	New Jersey QSO Party
Sept 4 - 5	ARRL VHF QSO Party
Sept 11 - 12	European DX Contest – Phone

CW COUNTY HUNTERS CONTEST

Starts: 0000 GMT Saturday, July 17
Ends: 0600 GMT Monday, July 19

The CW County Hunters Net (7055 and 14070 kHz) invites all amateurs to participate in the 1976 contest. All mobile and portable operation in less active counties is welcome and encouraged. General call is "CQ CH." Portable or mobile stations changing counties during the contest may repeat contacts for QSO points. Stations on county lines give and receive only one number per QSO, but each county is valid for a multiplier. Each station may be worked once per band.

EXCHANGE:

QSO number; category (portable = P, mobile = M); RST; state, province, or country; and county (for US stations only).

SUGGESTED FREQUENCIES:

3575, 7055, 14070, 21070, 28070 kHz.

SCORING:

QSOs with fixed stations count 1 point per QSO; portable or mobile stations score 3 points per QSO. Multiply the number of QSO points times the number of US counties worked. Mobiles and portables should calculate their score on the basis of total contacts from within each state.

AWARDS:

Certificates will be awarded in three categories.

F – Highest fixed or fixed portable station in each state, province, and country with 1,000 or more points.

P – Highest station in each state with 1,000 or more points operating portable from a county which is not his normal point of operation.

M – Highest mobile in each state operating from 3 or more counties with a minimum of 15 QSOs per county.

Trophies will be awarded to the highest single operator station in the US in categories P and M. The awards committee will issue additional awards where deemed appropriate.

LOGS:

Logs must show category, date/time in GMT, station worked, exchanges, band, QSO points, location and claimed score. All entries with 100 or more QSOs *must include a check sheet* of counties worked or be disqualified from receiving awards. Enclose a large SASE for results. Logs must be postmarked by September 1, 1976, and be sent to: CW County Hunters Net, c/o Jeffrey P. Bechner W9MSE, 673 Bruce Street, Fond du Lac WI 54935.

QRP AMATEUR RADIO CLUB INTERNATIONAL, INC. 1976 ANNUAL AUGUST QRP CONTEST

Starts: 2000 GMT Saturday, August 21
Ends: 0200 GMT Monday, August 23

This contest is open to all amateurs, and all are eligible for awards.

EXCHANGES:

MEMBERS = RST/RS; State/province/country; QRP nr. NON-MEMBERS: RST/RS; State/province/country; Power.

SCORING:

Stations can be worked once per band for QSO and Multiplier credits. Each MEMBER QSO counts 3 points, NON-MEMBER QSO 2 points. Stations other than W/VE count as 4 points. Score = QSO points times total number states/provinces/countries PER BAND times power multiplier.

MULTIPLIERS:

More than 100 Watts input power . . . X1; 25-100 Watts input power . . . X1.5; 5-25 Watts input power . . . X2.0; 1-5 Watts input power . . . X3.0; Less than 1 Watt power . . . X5.0.

FREQUENCIES:

CW = 3540, 7040, 14065, 21040, 28040. SSB = 3855, 7260, 14260, 21300, 28600. Novice = 3720, 7120, 21120, 28040. All freqs. are plus or minus 5 kHz or so, to dodge QRM.

CALL:

CQ QRP DE (callsign).

AWARDS:

Certificates to the highest scoring station in each state, province or country. Other places will be given depending on activity. One certificate for the station showing three "skip" contacts using the lowest power.

LOGS:

Send logs to: E. V. Sandy Blaize W5TVW, 417 Ridgewood Drive, Metairie LA 70001. Send full log data, including your FULL name and address, bands used, equipment, antennas and power used. Entrants desiring result sheets should enclose a #10 SASE. Logs must be received by September 30, 1976 to qualify.

EURD AWARD

This award is offered by the DARC in three classes for two-way RTTY contacts with different European countries and prefixes. All amateur bands, including VHF, may be used. All contacts must be confirmed and dated after Jan 1st, 1965. Contacts during the RTTY WAE DX Contest can be used for EURD endorsements, provided the log of the requested station is also received. Requests must

LETTERS

THE PROVERBIAL LADDER

73 and its staff have helped me more than *QST* and the staff that publishes that magazine. Matter of fact, I'm thinking seriously of not renewing my subscription to *QST* when it expires this coming August. The ARRL hasn't been that much of an aid in my climb up the proverbial ladder of hamdom.

Your records, which I'm certain you keep for at least a year, will show that I'm not only a subscriber, but nave ordered, thusfar, your 14 wpm tape. Which, by the by, is "working" after about 2 hours of practice. Of course, I've had X number of hours on the air as a Novice, and other means of practicing CW for that damn FCC General Exam.

I am going for the General Exam and would like not to blow my hard-earned $4.00 and time sans at least studying your *General License Study Guide*, for which I've enclosed my personal check for $5.95. When (positive thinking, as opposed to "if") I get my General, I'll be happy to let you know.

Always good luck to you and your crew, and keep on saying what you please when you please.

Joe Marymount WN2TXQ
Teaneck NJ

THE WRONG PEW

Thanks for your excellent service in regard to my subscription. I really didn't think I would receive all the copies I requested, and so quickly. You rank far above any magazines I have subscribed to. Matter of fact, I shouldn't even compare you with other magazines. Being a man of good faith, I should have believed and expected great things from you. Well, perhaps I was weak — but am now made strong by people interested in other people. Enclosed is a Reader Service request I know I will receive the same prompt service.

You see, it's all-important for someone like me, who is just starting out in this ham business, to get all the encouragement possible. I don't know which rig to begin to shop for. With your help, I'm sure I'll be able to make a wise and educated choice.

Keep the articles coming which push us beginners along, because we often get discouraged when there is no help around. We especially get a droopy mustache when we get bogged down in code. It's so hard to turn the corner from 12 wpm to 13 wpm.

Would you by chance know if anyone in my area willing to help me with that final step in code? Just about there, but not quite. Also, Wayne, I have a nice CB rig I'd like to sell someone. It'll help finance my ham rig. I have two brothers who are hams — both were into CB. Ah, the joys that are theirs now. I don't want to be left behind. So please help.

My brothers, Leo and Gene, are in other states, so all they can do is to keep the cards and letters pushing me.

As I go through the letters to the editor, I notice all the compliments — so what more can I add, but that I'm dealing with people and not just another money machine. Thank you!

Brother Andrew Patin, C.S.S.R.
Saint Alphonsus Church
224 Carrier Street, N.E.
Grand Rapids MI 49505

Brother Andrew, you are sitting in the wrong pew as far as code is concerned . . . stuck at 12 wpm indeed! This tells me plainly that you are trying to avoid the Wayne Green Code Cassette system of learning the code, a system which does not try to get you to learn the code at ten different speeds . . . just at two . . . six wpm and 14 wpm. Obviously, you are trying to penny pinch and not invest in the 14 wpm code cassette which 73 happily foists off on unsuspecting readers . . . and this is the root of your trouble, and a well rounded round of tsks for any brothers of yours who steered you into the 12 wpm cul de sac. Thanks for the nice letter otherwise and harken to the above. — Wayne.

"Al" Neilson

Having just received my April issue of *73*, I thought I had to put pen to paper to compliment the gang on producing what surely must be rated as the best ham magazine in the world! I subscribe to quite a few American and British mags, and for sheer quality, quantity, practicability and up-to-date state of the art articles, *73* not only beats the rest — it murders them! I am sure my postman has the lifelong task of delivering my *73* mag!

The only disadvantage is that *73* spoils me for choice, as any IC article causes me to have constructor's itch.

Keep up the great job and don't change anything (except perhaps the price, which is understandable!).

Al Neilson G4CVZ
Liverpool, England

HEAD AND SHOULDERS

We really enjoyed "The Smart Power Supply," by WA4SAM in the March issue of *73*.

The same IC has been used here for about four years now with great success. We use it for controlling an electroformation process. We are using 144 plug-in cards almost identical to John's card. The cards control 345 transistors mounted on water-cooled heat sinks. For dc power we use two rectifiers rated at 500 Amps, at 75 volts each.

John's article was well written and to the point. His kind of article caused us to subscribe to *73* in the first place!

Keep up the good work, and keep the computer articles coming each month! *73* is head and shoulders above the other ham rags!

Wm. Dunnivant
Commercial Electronics
Baxter Springs KS

ROTTEN LITTLE KID

Last week I mailed you a letter inquiring as to the whereabouts of tapes I ordered. Today, I finally received the tapes! Your package was postmarked February 11, 1976. It took our glorious, gov't operated Post Office 12 days to move the tapes from N.H. to Ala. Heaven help us if the liberal politicians have their way and take over the oil companies. Can you imagine the oil delivery? The tapes are excellent!

Lucius B. Ramsey
Spanish Fort AL

A short note to praise the 13+ wpm tape. I sent for one and used it a total of 6 hours and 35 min. I took the General test at Syracuse April 14 and the test (code) sounded like 10 wpm — and I passed. Had taken the test last Jan., but blew the code so I took the theory and got a Tech. So I tried your tape and it really gets the job done. Now I am going for my Advanced. After all, my 19 year old son passed his Advanced last Nov., the rotten little kid.

Waldo Longwell, Jr. WA2EMJ
Horseheads NY

ADDS, TOO!

I am an owner of the Texas Instruments SR-50 calculator. One day I was listening on 2 meter FM and working out a math problem at the same time. I noticed that the oscillator in the SR-50 was generating a respectable signal on 146.82.

In fact, the LED display generates random noise pretty much evenly distributed through the rf spectrum. It really makes a good noise source to peak up a VHF receiver. By wrapping 2 or 3 turns of wire around the display and connecting the wire to the antenna jack, you create an instant noise source. This probably holds true for any calculator with an LED display.

If you have an SR-50, press 99. Then press the factorial key. You will hear a pulsed 1 kHz tone in your receiver. This is an error display, so any answer that the SR-50 sees as invalid will cause the display to blink.

This blinking occurs about twice per second, depending on battery conditions. This beeping is especially nice when the natural noise level is especially high. Oh, yeah, the SR-50 can add, too!

Paul J. Dujmich WA3TLD
McKeesport PA

PLEASING MARY

Just a short note to tell you I enjoy your publication a great deal. Sometimes they're a little late getting to me here in the Philippines, but then I'm not always in town when they arrive. Anyway, I hope you will forgive me

for sending in my Reader Service forms a little late; I didn't mean to upset Mary — I didn't even know . . . anyway if it helps I will make a few extra forms myself to send in next month (pestilence in triplicate). If all your readers do likewise, I'm sure Mary will be very pleased!

J. B. Fields
Subic Bay, R.P.

"MIRANDA" OF MAGAZINES

Thanks for the "announcement" on the Table of Contents page in the April 1976 edition of *73*. It looked like a "throw-in" as a "rub it-in-yar-nose" adjudicative settlement. Sometimes the Telephone Company can be didactic to the point of absurdity. The "announcement" smacked of the literary style used by the Surgeon General. No doubt the California Court started an irreversible trend . . . and your mag had it first once again . . . Think of it, a Section 315 for publishing; a "Miranda" of magazines . . . wow . . . articles on two meter transmitters now have to be preceded with: "Note to readers: Construction of this project is illegal if you steal the parts to build it." The April antenna issue should have announced boldly: "Construction of any antenna in this super edition of *73* could lead to your violating peeping tom laws" . . . or how about articles on weather satellites . . . "Note: Information obtained from weather satellites may not be sold to foreign governments for purposes of aggression."

The California Court quite obviously has little appreciation for the integrity of your clientele. Further, they understand little about our need to know. Your reaction was probably like mine and thousands of others: "So what? Most knew how it was done anyway." What difference does it make? Telcos find it hard to give you information which is "cleared" for dissemination, so now maybe some of our "legitimate" questions will be answered. Quite frankly, the article gave me a new respect for the importance of "in-band energy suppression" on my approved QKT coupler. Thanks to that big bold announcement, I was able to relocate and reread the article to see if I had missed anything the first time around.

John S. Hollar W3JJU
Harrisburg PA

TOO LONG TO WAIT

I want to say what I have been going to for some time. In my opinion your magazine, large or small format, is undoubtedly the most up to date with state-of-the-art on the market today. The only problem is, unlike other ham magazines, one month is too long to wait between issues. Keep up the good work.

K. L. Freeland W1ANF
Nashua NH

PROUD W

Because I read another ham's *73* and admire it and its publications, here's a communication pertinent to the times and the year:

Our W and K prefixes have been so well known throughout the world for such a long time that everyone knows the American hams thereby. There is no reason to masquerade as something else with that alias, "AC" ! I'm proud to have held W1, W8 and W9 calls over 44 years and shall continue with the proud "W".

Temple Nieter W9YLD
Evanston IL

ACE

Everybody, it would appear, has a name. Amateur operators are called hams (ugh!), operators in the Citizens Radio Service are CBers, and so forth. But what of the person who likes to experiment with computers???!

In answer to the question above, I would like to propose that a person who "plays" with computers be called an "ACE": *A*mateur *C*omputer *E*nthusiast. What do you think?

Theodore J. Cohen W4UMF
Alexandria VA

The term "Computer Hobbyists" may stick . . . if any newsletters in the field discover how to spell it (several spell it hobbiests). Most hobbies have not developed terms such as "ham" . . . not that we know for sure where that term really got started. Camera hobbyists are called camera nuts, camera fiends, etc. Amateur astronomers are called just that. ACE is ace with me, but I'll bet you can't make it stick. — Wayne.

TAPEWARN

While the "three-for-a-buck" cassette tapes are clearly unsuitable for data storage use, our experience is that "the best you can get your paws on," as suggested in your interesting "Nifty Cassette" article (May, 1976), is a potentially considerable expense that is usually not required. While price is a general indicator of oxide integrity and of construction quality, it is an inefficient and costly guide, since the extended high frequency performance is not at all necessary for data uses.

Extensive testing by a consortium of local schools and colleges resulted in the recommendation of three brands for a similar data storage use: Maxell, Scotch Highlander, and Omega. Highlander tapes are widely distributed at modest cost, while the Omega is a private brand, manufactured by 3M, and distributed in the midwest. The latter has proven particularly suitable in our own system, as it is lowest in cost, yet utilizes a fine mechanical system of stainless steel chutes rather than rollers; moreover, it is available in 30 minute length, required by some drives and no longer widely available in quality tape lines. We recommend the 30 or 45 minute lengths over 60 minute size, as the tape is thickest in these sizes. Using 30 minute Omega tapes for semicommercial use, we have had no problems attributable to tapes in several months.

I caution against purchase of "digital tapes" at premium price; at least one custom "digital cassette" label is simply a rebranded, untested, standard line TDK audio cassette. On the rare times that real-and-true *data certified* tape cassettes are required, we have found that Artec International has attractive prices — especially in modest quantities — at their nationwide branches. If readers should desire Omega cassettes in locations where these are not available, our school bookstore will supply purchasing assistance upon receipt of an SASE. Send SASE to: Resource Access Center, 3010 4th Avenue South, Minneapolis MN 55408.

Richard B. Koplow
Minneapolis MN

NO DREDGING

I spoke to you one day last year when you called Gary W3DTN looking for FCC info to publish. My question to you at the time was, how good are those new code tapes? Are they really different? You said they were much better than Brand X and Y. You know — you were right. They are good. Thanks.

Now I have a question for this year. As background, I have a 240Z and I understand you push around a Z yourself, so maybe you will be sympathetic to my problem. I want to run 6 and 2, plus broadcast, off one antenna (hopefully replace the B/C antenna with a Larsen). Thus far, I have found no understandable info on splitters, filters, matching units, etc., that would help. As I don't want to clutter up an otherwise clean car with multiple antennas — I need help. Any chance you could dredge up something to publish on the subject?

Marvin T. Storey WA3RKA

OH, HENRY!

I would like to take this opportunity to express my pleasure with the superior service provided by Henry Radio. I have had several dealings with the Butler, Missouri store by mail during the last year and have always found their service to be very prompt and highly satisfactory.

Ken Morgan WA5VUZ
Albuquerque NM

ALDELCO DELIVERS

You may have received a few letters of complaint concerning the failure of Aldelco to deliver 2N5590 rf transistors. We had an unfortunate situation in that we inadvertently advertised the price of this unit at $4.15, which is below our cost. We sent out our entire stock of 2N5590s and immediately ordered more. Delivery from the factory has been held up and we hope to be able to fill every order at the $4.15 price in the next few days, even though we lose money on every order sent out. Being new in the mail order business, we are trying to build a reputation for good service and quality merchandise. Every order received is sent out within 48 hours if we have the item in stock. However, like any other company, we have our problems like outbreaks of the flu, vacations, etc. We will, however, continue to do our best to serve our customers.

Alfred G. Smith
Aldelco
Lynbrook NY

IN LOVE

Okay, I cannot put it off any longer: I must write and tell you how much I enjoy *73 Magazine*. The May 1976 issue came recently and, as usual, I quickly leafed through it and noted all the good articles I would peruse at my leisure. Later I shall fold down the corners of those pages on which I find something of special interest. Even later I may index everything.

I admit it — I love *73*. Before you people get puffed up with pride, though, there are other magazines I also enjoy. In fact, the mailperson must wonder if I do anything but read magazines. Magazines such as *The Audio Amateur* (I'm glad to see they've wised up and moved to N.H., even if it is just down the street from *73* Some day I must come to Peterborough: then I can not only visit *73*, *TAA*, and Old Colony Sound; I can also drool over the tools at Brookstone. Ah, heaven . . .), most of the *Popular Whatevers, Analog, Scientific American, Track & Field News*, etc. However, so far only *73* (and, yes, Wayne) has inspired me to think about writing articles. I have even gone so far as to jot down ideas. And

I'm not even a ham yet, although I'm working on it, helped considerably by your study guides and code tapes.

Keep up the good work.

Gordon J. DeWitte
Somersworth NH

P.S. Count me among those pleased and impressed with James Electronics and S. D. Sales. Both have been great.

NOBODY ELSE WILL

Today I heard a story on WBBM (780 AM in Chicago) which reported that an amateur radio station was misguiding aircraft on landing at Rome's airport.

I called the station and complained. They gave me the number of Reuters, the source of the story. The complete story filed in Rome stated that authorities believed the problem was due to a terrorist group. I called WBBM back and explained that they should not give incomplete stories when the meaning thereby is completely changed.

Both the station and Reuters commented that I was nitpicking. Not at all. There are now at least 3 people in the news business who now know the distinction between a terrorist with a pirate radio and an amateur radio operator.

We have to start somewhere. If amateurs don't defend themselves, nobody else will.

Keep stirring things up.

John Lorenz WA9RDV/9
Kankakee IL

AUSTRIAN WELCOME

The Austrian Radio Amateur Society (ÖVSV) celebrates its fiftieth anniversary this year. From June 17th until June 20th, 1976, there will be a large festivity at Krems an der Donau (near the Wachau, Lower Austria), in memory of the foundation of the ÖVSV. We will be most pleased to welcome as many XYLs, YLs and OM from abroad as possible.

Here is a general summary:

Thursday, 17th of June: Approach competition on 144 Mc to 146 Mc from 1 pm to 6 pm.

Friday, 18th of June: Foxhunting competitions. Participants from abroad are most welcome. 80m foxhunting in the morning, 2m foxhunting in the afternoon. In the evening there will be a jolly evening with "Heurigen" (new wine) at Langenlois.

Saturday, 19th of June: Sightseeing at Krems. Opportunity to make a boat trip on the Danube to the famous Wachau. In the afternoon: coach trip to the Wachau and the abbey of Melk. In the evening, a big ball and distribution of awards at the Stadtsaal Krems. The military band of the Niederösterreich command will play.

Sunday, 20th of June: Memorial ceremony, speeches and symphony concert. Afterwards, a cold buffet. Afternoon and evening: farewell party at Stift Göttweig (abbey of Göttweig).

Organization center: Parkhotel Krems. Room reservations (priced between 100 and 350 Austrian schillings): Fremdenverkehrsamt Krems, Kunstlerhaus, WichnerstraBe, A-3500 Krems, Austria.

To commemorate the fiftieth anniversary of the ÖVSV, all OE stations have been authorized to use the prefix OE50 from the 1st of April until the 1st of July. During the same time, a special station will operate with the callsign OE50/3XKW.

To help with the approach, there will be some repeaters active on the 2m band, especially OE3XHW (Hohe Wand) on R5, OE3XPA (St. Pölten) on R8, OE1XWW (Wien) on R6 and a special repeater, OE3XSA (Krems), on R4.

Participants from abroad will have plenty of opportunity to meet many Austrian OM personally. We look forward to an eyeball QSO at Krems an der Donau!

Dr. Emmerich Rath OE3RE
Langenlois, Austria

EXTRA DOUGH

How many of you go out and spend $50 or more for a 12 volt power supply to run your solid state two meter rigs? I purchased a Regency HR-2B without the ac power supply. Next I went around to the local gas stations until I found a good used 12 volt battery (which I only paid $1.00 for). Then I ordered a small trickle charger from Olson Radio for $1.49. I have been running the rig ever since.

Also, this makes for a nice emergency setup in case the ac power goes off. With the extra dough left over, take the XYL out for supper.

Richard A. Little K9EEH
Sterling IL

LEAN ON OTHERS

William Cook's letter in the May *73* has moved me to respond. My sympathy goes out to you, Bill. Constructing a transmitter, receiver, T-R circuit, or whatever, from scratch can be an overwhelming project for the beginner.

I've built receivers, transmitters and test items from magazine articles, and frequently departed from the author's suggested parts layout because some critical item or other had to be substituted. Bill, things are never perfect. Even prospective hams have to make trade-offs and compromises. So you might as well start now.

This letter is written by a guy who used to invade the junk heaps in search of cast off radio parts. Once I even brought home a rubbish-contracted skin disease. Many of the scrounged parts ended up in transmitters used on the air. You see, money to buy parts was kind of scarce in those years.

My recommendation to you is to look for kindred souls in your area through Ham Helps or by listening on 75 or 2 meters and tracking hams down from their addresses in the Radio Amateur's Callbook Magazine. (Sneak a look in the Callbook while visiting a radio parts store some time, if it's too expensive to buy one.)

Then get acquainted. Lean on others for awhile, until you learn to walk alone in this tremendous hobby. Maybe some day you can become a leader. Good luck.

Paul L. Schmidt W9IDP
Bloomfield IN

P.S. Your town of Alpena, Mich., has some 30,000 people. There should be a ham or two in town who can help you get started.

SWAPPER

I'll be glad to swap my time in helping you set up, program, debug, etc., a microprocessor, in exchange for using or acquiring a system, the hardware. I have background in systems/programming: many systems, many languages, assembly and higher level languages. Please contact me to discuss situation.

Toby Maki
102 Minott Rd.
Westminster MA 01473

YASME: THE BLOW STRUCK!

This is a report on the YASME operation during the month of March in the Republic of Nauru under the call C21NI. Approximately 7500 QSOs were made with amateurs in 116 countries. While, at other stops in Pacific areas, Europe was workable from only a few minutes to a very few hours, from C21NI there were some beautiful openings to Europe. One day the band was continuously open to Europe for 10 hours.

The first QSO from C21NI was with JA5DH on 1 March 1976. The last QSO was with UB5JBY on 25 March 1976. Some 1500 QSOs were made during the last half of the ARRL SSB DX competition and again some 1500 QSOs were made during the last half of the ARRL CW DX Competition.

We made arrangements by radio for our next stop to be YJ8 (New Hebrides). We had written permission to operate there. We had an apartment rented there (from YJ8DE). We had our plane tickets, etc. It was impossible in Nauru to obtain a visa to anyplace, but we had been told in the Fiji Islands (by the French Chargé d'Affairs) that no visa was required for a 30 day visit. We arrived safely in Vila, New Hebrides; all of our gear was taken off the plane; people were waiting to greet us. Transportation was waiting to take us to our apartment. Then the blow struck! The Head of Immigration (British) said that we could not enter the country without a visa and that he would not issue one in Vila. We were ordered to get back on the plane that we had just left and leave the country immediately. We protested and almost refused to go — however, there were lots of policemen there and it appeared that we would be either forcedly put on the plane or forcedly taken to jail. After holding up the plane for nearly an hour, we found ourselves and all of our gear back on the plane bound for New Caledonia.

Lloyd Colvin W6KG
Iris Colvin W6DOD
Noumea, New Caledonia

THE MIDAS TOUCH

It is unfortunate that there are those who feel that criticism should be expurgated from *73*. There are many countries today where criticism is discouraged and the press contains references to omniscient leaders whose infallible decisions have meant the Midas Touch to the fortunate publications who are privileged to pay taxes and make other support (and who might disappear if they were to voice any critical comments). I suppose if I were high on the totem pole, I would not like criticism either; but criticism is good for the public — it keeps officials on their toes, keeps people honest, and in the long run is beneficial to all society. Whereas I may not agree with editorial content, I support a person's right to that opinion and his right to publish it. That's the American plan! (And we can buy tubes from Amperex and RCA!)

Paul Schuett WA6CPP/WA7PEI
Wallace CA

R/Os NEEDED

For benefit of any readers who are unemployed, please place this small note somewhere in *73*: " Radio Officers needed urgently. Six months endorsement program with pay very likely."

Valley Mills TX 76689

RACE RESULTS

This past February I wrote to you complaining of the lateness of my first issue of *73* (I had not received my January issue yet) and challenged you to beat the ARRL response to a similar complaint some years back that I made. Namely, my challenge

AMSAT

FIELD DAY WEEKEND

Since extra Field Day points can be gained by making contacts via the OSCAR satellites, it has been decided to change the operating schedule of OSCAR 6 for FD weekend. In order to keep the satellite's battery more fully charged, the first three orbits of the 26th of June which would normally be on will be kept off. The following AMSAT-OSCAR 6 orbits will be turned *on* for FD QSOs (starting Sat., June 26, 1976):

Orbit	Eq. Crossing Time (GMT)	Longitude °W	Call Areas in Range
16906	18:07	327.6	Northern W1, 2, 3, 8, 9, Ø, 7 states & VE, KL7, KH
16907	20:02	356.4	Same as previous orbit
16908	21:57	25.1	W1, 2, 3, 8, 9, Ø, VE, KL7, northern W4 & W7
16909	23:52	53.9	All states except KH6, all VE
16910	01:47	82.6	Same as previous orbit (June 27)
16911	03:42	111.4	W5, 6, 7, 8, 9, Ø, VE3-8, KL7
16915	11:22	226.4	W1, 2, 3, 4, 8, 9, VE1-4
16916	13:17	255.1	All states except W6 & KH. VE1-6 & eastern VE7
16917	15:12	283.9	All states except KH6
16918	17:07	312.6	All states except southern W4
16919	19:02	341.4	Northern W1, 2, 3, 8, 9, Ø, 7 & VE, KL7, KH6
16920	20:57	10.1	W1, 2, 3, 8, KL7, VE & northern W9, Ø, 7

The uplink passband of OSCAR 6 is 145.90 to 146.00 MHz; downlink is 29.45 to 29.55 MHz. AMSAT-OSCAR 7 will be in Mode B (70cm/2m) on GMT Saturday June 26. The uplink passband for Mode B is 432.125 MHz to 432.175 MHz. Downlink is 145.975 to 145.925 MHz. OSCAR 7 will switch to Mode A (2m/10m) at 00:00 GMT on Sunday, June 27, 1976. The Mode A uplink is from 145.85 to 145.95 MHz and the downlink is from 29.4 to 29.5 MHz. AMSAT-OSCAR 7 will be about 27 minutes behind its older brother OSCAR 6 during the Field Day weekend. The MAXIMUM effective radiated power for either satellite is 100 Watts. ERP equals the antenna gain times the power delivered to the antenna.

OSCAR 6 ORBITAL INFORMATION

Orbit	Date (July)	Time (GMT)	Longitude of Eq. Crossing °W

QRP TEST

All users of the 70 cm to 2m Mode B transponder of the AMSAT-OSCAR 7 satellite are invited to participate in a special three day low power (QRP) test which will occur on June 16, 17 and 18, 1976. The test will begin at 0000Z, 16 June, when the satellite switches from Mode A to Mode B on orbit #7245. It will be kept in this mode by AMSAT telecommand stations located in Canada and Australia. The final orbit of this three day test will be #7282 on Friday, June 18.

All stations using the transponder are urged to run *10 Watts* effective radiated power or lower, and those who cannot reduce power to this level are asked not to transmit in the 432 MHz uplink passband, since their presence will reduce the effectiveness of the many low power users who will participate in the QRP test. Signal reports sent should include the erp being used (i.e., RST 569 erp 5 W), so that those listening can get an idea of how effective low power can be via AMSAT-OSCAR 7 when the high power stations aren't hogging most of the available power.

Remember that one Watt into a 10 dB gain antenna system will produce the maximum recommended 10 Watts effective radiated power. If an exciter runs 10 Watts or more output, a half wave dipole will be a big enough antenna to use, and, if more attenuation is needed to reduce the erp, an old piece of lossy coaxial cable can be added to the existing transmission line. It doesn't really matter how the 10 Watts erp is achieved. The important thing is to run QRP for the three day test and send the results along with a station description to AMSAT, PO Box 27, Washington DC.

FOR YOUR EYES ONLY

Microprocessor/Microprograming Handbook
by Brice Ward
293 pp., $6.95.

The economic advantages of the microprocessor, or "computer on a chip," have made them a popular and commonplace device in many commercial and industrial applications. The prolific use of microprocessors is bringing this technology to any forward-thinking person. As one becomes more familiar with the capabilities of microprocessors, his imagination devises applications.

Microprocessor/Microprograming Handbook provides a coherent introduction to the world of microprocessing. This readable text examines the vocabulary, architecture, memory systems, machine language, and assembler language of this exciting new technology. It provides valuable insight for the student or hobbyist interested in automation, electronics, or small computer applications, the engineer or technician who may be familiar with one microprocessor but would like to sample other architectures and their capabilities, and the business manager whose product could be improved by the incorporation of a microprocessor or who would like to be more familiar with the devices his staff is using.

Microprocessor/Microprograming Handbook is more of an introductory text on 4 and 8 bit microprocessors than a thorough handbook. Although there are more than 40 manufacturers of these devices, this text discusses the Motorola 6800 and draws heavily on the Intel 4040 and 8080 devices. Reference is made to 2 and 16 bit devices, but little information is provided.

As a text, it provides a sweeping view of the topic with enough detail to obtain a thorough understanding of several specific uPs. The devices detailed in this text are among the most popular used today. Its general ease of reading, along with helpful appendices for Abbreviations, Terminology, Manufacturers, and Support Chip Sets, provides valuable footing for amateurs and professionals interested in knowing more about these devices.

Electronic Conversions, Symbols & Formulas
by Rufus P. Turner,
Tab #750, 224 pp., $4.95.

This rather inclusive reference includes practically every formula that an electronic hobbyist would need for any use. Basic mathematical laws, functions, formulas and constants are presented, followed by fundamental and useful electronic design formulas.

Circuit design is usually accomplished in one of two ways — the amateur's way (cut and try) and the engineer's way (figure it out first). With this compendium of the needed data, the engineer's way isn't so hard after all, thanks to calculators. Wonder how to design that bandpass filter or wind that coil? Do the abbreviations f_{co} and h_{oe} confuse you? They, with all other common electronic abbreviations, are there. Wonder how to convert Maxwells to Webers or footpounds to kilogrammeters? These and other conversions, common and obscure, are compiled.

Let's face it: Most of us don't remember those formulas we saw on

our license exams, except the easiest. If you should need them, here they all are. It practically makes electronics math look easy.

Op Amp Circuit Design
& Applications
by Joseph Carr
Tab Books #787,
Blue Ridge Summit PA,
282 pp., $6.95.

The most popular and useful device to emerge from the development of linear ICs is the operational amplifier. Their versatility is amazing, as they are an inexpensive and convenient approximation of the "perfect" amplifier.

This new book brings together the theory and circuitry needed to apply op amps to a wide range of applications. After a thorough, well illustrated description of op amp basics, applications are presented for use in computation, test equipment, active filters, power supplies and more. There's not much you can't do, it seems, with today's op amps.

Besides the conventional op amps, exotic and newer devices are also covered, keeping the circuit designer up to date. Anyone with an interest in designing or building audio, power supply, instrumentation or other linear circuitry would do well to read this book.

Build-It Book of Miniature Test
& Measurement Instruments
by Robert P. Haviland
Tab #792, 238 pp., $4.95.

Here is a complete guidebook for the construction of a wide range of test instruments. None of them is expensive to build, and all are compact and modern.

Complete instructions are given for all of the devices, including printed circuit layouts and parts lists. There are also chapters on general construction practices, to help your projects look professional. Newcomers to construction would do well with this book, as it is not written exclusively for the expert. Experts will still find use for the gear, though.

Included are RCL bridges, audio signal generators, general purpose test amplifiers, a Q-meter, sound level meter, and digital counter. And there are more circuits than that. Fifty measurement functions are possible with the devices described, and that's not bad for $4.95!

SOCIAL EVENTS

FLUSHING NY
JUNE 5

The Third Annual Hall of Science Radio Club auction and flea market will be held Saturday, June 5 at World's Fairgrounds, Flushing, L.I. Admission $1.00, sellers $2.00. No sellers commission but 10% fee on auctioned items. Zoo, boating, children's farm, art and science museums adjacent. Field Day goodies galore. For more information write: Box 1032, Flushing NY 11352.

HUNTINGTON WV
JUNE 6

The Tri-State Amateur Radio Association (TARA) 14th Annual Hamfest will be held Sunday, June 6th at 11:30 am at Camden Park, Rt. 60 West, Huntington WV. Talk-in W8VA/8 146.04-.64, .16-.76, and .34-.94. For more information and tickets write to: TARA, PO Box 1295, Huntington WV 25715.

WINFIELD PA
JUNE 6

The Penn-Central Bicentennial Hamfest will be held Sunday, June 6 at the Union Township Volunteer Firegrounds, Winfield PA, 11 miles south of I-80 on Route 15. Contests, auction, flea market — start at noon. Registration $2; XYL, children free, free parking. Contact W3GPR.

BELLEVILLE MI
JUNE 6

The Southeastern Michigan Amateur Radio Hamfest will be held Sunday, June 6, 1976, from 6 am till 4 pm, at the Wayne County Fairgrounds, Belleville, Michigan. 20 minutes from Detroit, 10 minutes from Ann Arbor. I-94 at Belleville Road Exit. Featuring: indoor exhibits, swap and shop, trunk sales, food and refreshments, camping space adjacent to fairgrounds available at a nominal free, and hotel and motel reservations will be available. 5 major prizes. Tickets $2 advance, $2.50 at gate. For more information and tickets write to: Hamfest, Box 1976, Belleville MI 48111. Talk-in 37/97 rpt — 52 simplex. Sponsored by: A.R.R.O.W. Repeater Inc., WR8ADH.

OLD WESTBURY NY
JUNE 6

The Electronic Flea Market sponsored by L.I. Mobile Amateur Radio Club (LIMARC) will be held Sunday, June 6, 1976 from 9am to 4 pm (rain date: June 20) at the N.Y. Institute of Technology, Rte. 25A and Whitney Lane. Admission $1 per buyer; $2 per space seller. For additional information call W2KPQ (516) 938-5661. Talk-in on 25/85.

PISCATAWAY NJ
JUNE 6

The Tri-County Radio Association Inc., flea market will be held June 6, 1976 at Nick's Grove, 318 William Street, Piscataway NJ. Opens at 10 am, admission $1, tables $4, half tables $2. Door prizes. Talk-in 146.52, 147.855/147.255. For further information call (201) 725-0778 or (201) 752-4307 or write: PO Box 412, Scotch Plains NJ 07076.

MANASSAS VA
JUNE 6

The Ole Virginia Hams A.R.C. is sponsoring its second annual Mid Atlantic area "Quality" Hamfest for Sunday, June 6, 1976, at the Prince William County Fairgrounds, Route 234, ½ mile south of Manassas, Va. Directions: take I-95 to Route 234 at Dumfries, Va., or I-66 to the Manassas exit, then south on Route 234. Talk-in on 146.37-97, 147.84-24 and 146-52 simplex. Featuring — large display and exhibit area, electronic flea market, and door prizes. For more information and advanced registrations write to: WA4GVX, 1708 Sharp Drive, Woodbridge VA 22191.

PRINCETON IL
JUNE 6

The Starved Rock Radio Club Hamfest will be held June 6 at the Bureau County Fairgrounds, Princeton, Illinois, same place as last year. Free coffee and doughnuts from 10 to 10:30 am. Camping and trailer space on a first come first served basis for a nominal fee. Official dedication of Starved Rock Repeater by ARRL officials. Advance registration, $1.50 until May 20, after that/or at gate $2.00. For more complete information, motel list, maps, etc., furnish long SASE. For reply, write: Starved Rock Radio Club W9MKS, RFD #1, Box 171, Oglesby IL 61348. (815) 667-4614.

SHAKER HEIGHTS OH
JUNE 11-13

The Midwest Affiliation of Computer Clubs (M.A.C.C.) is sponsoring the first annual Midwest Regional Computer Conference at Cleveland in June, 1976.

The event is being hosted by the Cleveland Digital Group and will take place in Shaker Heights, Ohio at the Stouffer Somerset Inn, 3550 Northfield Road. Dates are June 11, 12, and 13. Tickets are $2.00 in advance and refreshments will be available.

The event will have a Trade Show type format with each manufacturer having a booth or booths for his own use. Additional demonstrations, technical sessions, games (such as Star Trek), etc., will be going on almost continuously. We are planning on a rather large flea market and, of course, program duplication, copying and media conversion facilities will be available.

More complete information and tickets can be obtained by writing to: The Midwest Affiliation of Computer Clubs, PO Box 83, Brecksville OH 44141.

SIOUX FALLS SD
JUNE 12-13

The Sioux Falls Amateur Radio Club, Inc. and the Sioux Valley Repeater Association, Inc. will hold the 1976 South Dakota Ham Picnic in Sioux Falls on June 12 and 13 at the Sioux Empire Fairgrounds on Sioux Falls' west side, ½ mile east of Interstate 29 and the 12th Street off ramp — follow the "QSY" signs. A talk-in will be on 3950 kHz by the S.F.A.R.C. Club station, WØZWY. Members of the S.V.R.A. will provide information and assistance on the WRØACK 16/76 repeater. For further information, please send an SASE to Sioux Falls Amateur Radio Club, PO Box 91, Sioux Falls SD 57101.

ATLANTA GA
JUNE 12-13

The ARRL Southeastern Division Convention and the Atlanta HamFestival 1976 will be held on June 12-13th at Dunfey's Royal Coach Motor Hotel, I-75 at Howell Mill Road, Atlanta GA. Special HamFestival rates of $16 single, $21 double are in effect. Individual registration is $3 in advance, $4 at door; family registration $5 in advance, $6 at door. Flea market spaces (outdoors) are $5 each, first come, first served. For more information and pre-registration forms, write: Atlanta HamFestival 1976, 53 Old Stone Mill Road, Marietta GA 30062 or telephone area (404) 971-HAMS day or night.

ARNOLD MD
JUNE 13

The Maryland Mobileers Amateur Radio Club will hold its Sixth Annual Hamfest on Sunday, June 13, 1976 at Anne Arundel Community College, Arnold, Maryland. Gates open at 9 am. Registration: $2. Tailgaters: $3 plus registration fee. Drawings to be held at 3 pm. First prize: $200 Savings Bond. Talk-ins on 146.10/.70 — 146.52 — 146.16/.76.

WILLOW SPRINGS IL
JUNE 13

The 19th Annual ABC Hamfest will be held Sunday, June 13, 1976 sponsored by the Six Meter Club of Chicago, Inc. Located southwest of Chicago at Santa Fe Park, 91st and Wolf Road, Willow Springs IL. Advance registration $1.50; at the gate $2.00. Large swap row, picnic grounds, AFMARS meeting, refreshments. Advance tickets from Don Marquardt K9SOA, PO Box 79, Lyons

IL 60534 or any club member. Talk-in on 146.94 FM or WR9ABC 37-97 (PL2A).

GRANITE CITY IL
JUNE 13

The Egyptian Radio Club, Inc., W9AIU Hamfest will be held Sunday, June 13, 1976 at the club house located north of Granite City, Illinois, ¼ mile south of the Old Chain of Rocks Canal Bridge. Swapper Row, games for the kiddies, lunch served, cold drinks, ladies' white elephant sale and Bingo. Talk-in on AF9ACA 146.76. Admission free.

AKRON OH
JUNE 20

The Goodyear Amateur Radio Club WA8UXP of Akron, Ohio will hold their 9th Annual Fathers' Day (Hamfest Picnic), on June 20, 1976, at Wingfoot Lake Park located east of Akron, Ohio, one mile west of Suffield, Ohio, on County Rd. #87 and near County Rd. #43. Huge flea market, displays, swap and shop, prizes on the hour, picnic tables available. Adult and children's play area all day. Join us for an enjoyable day of entertainment. Hours: 10 am to 6 pm. Family admission S2 prepaid; S2.50 at gate. For details, tickets, map and program, write to Floyd T. Gilbert WB8ALK, 1976 Newdale Ave., Akron, Ohio 44320.

SCHEREVILLE IN
JUNE 20

The Midwest Repeater Association with the Indiana Dunes Amateur Radio Club's Hamfest will be held June 20, 1976 at the Lake Hills Senior Citizens' Picnic Grove, 8100 Austin Road, Schereville IN, from 8 am to 5 pm. Food, drinks, door prizes, etc. Talk-in 146.31-.91 (WR9ADK) or .94, .52. Tickets or more information send SASE to I.D.A.R.C., PO Box 5, Dyer, Indiana 46311.

HONOLULU HI
JULY 3-4

The Honolulu Amateur Radio Club will hold its Hamfest/Swapmeet on July 3 and 4, 1976. The Swapmeet will be held on the grounds of the Kaimuki High School, 2707 Kaimuki Avenue, Honolulu, between the hours of 0800 am and 3 pm. Charges per stall will be $2. The Hidden Transmitter Hunt will start at 0900 am on 4 July 1976. The transmitter will operate on 146.52 MHz. Participants will meet at the Pancake House, Ala Moana Center, Honolulu, prior to 0900 am for contest instructions. Registration fee will be S1 per vehicle. Prizes will be awarded to the top 3 winners. For additional information and participation in the HARC Hamfest/Swapmeet, write: George Stillman KH6AN, PO Box 7111, Honolulu, Hawaii 96821.

DUNSEITH ND
JULY 10-11

The 13th Annual International Hamfest is scheduled for July 10 and 11, 1976 at the International Peace Garden between Dunseith, North Dakota and Boissevain, Manitoba. Many prizes to be won. For more information write: Craig R. Schmidt WBØGFZ, Co-Chairman, 1976 Hamfest, Reed Hall #302, North Dakota State University, Fargo ND 58102.

SANTA MARIA CA
JULY 11

The Satellite Amateur Radio Club is sponsoring the Santa Maria Amateur Radio Picnic And Swapfest to be held on Sunday, July 11th, 1976, beginning at 12 noon at the Newlove-Union Oil Picnic Grounds on Orcutt Hill. Watch for the signs marking the turnoff, 1 mi. south of Clark Ave. on US 101. Talk-in will be on 146.52 and 7280 kHz.

The highlight of the event is the Santa Maria style barbecue, to be served at 2:30 pm. All the meat, salad, beans, bread and salsa that you can eat. Soft drinks will be available, but bring your own beer.

The main door prize is a Tempo One 80-100 meter transceiver. Other prizes, too. Swap tables available at $3.00 each.

The meal alone is well worth the drive from L.A. or the central valley. Tickets are only S5.00 for adults/$2.50 under 12, and can be obtained by sending a check made out to Santa Maria Swapfest, Route 1, Box 55A, Santa Maria CA 93454.

Please obtain tickets in advance so that enough meat can be ordered.

CHARLESTON SC
JULY 11

The Charles Towne Hamfest will be held at the Gaillard Municipal Auditorium on Sunday, July 11, 1976, in Charleston SC. Registration is $2, which includes a door prize ticket. Activities include an indoor flea market, displays, home brew contest, CW copying contest, historic tours, and a special program on the Marconi Wells Fleet Wireless Station. Saturday activities include OCWA, MARS, S.C. SSB Net Banquet, and a hidden xmtr hunt. Talk-in on 34/94 and 3915. For further information write — Charles Towne Hamfest, Box 4555, Charleston SC 29405 or check into the S.C. SSB net on 3915 at 7 pm local time.

PORTAGE IN
JULY 18

The Lake County Amateur Radio Club's 2nd annual hamfest is July 18 at the Issac Walton League in Portage, Indiana. Take 1-94 to Ind. 249 exit, then north on Ind. 249 ½ mile. Tickets $1.50 advance, S2.00 at gate. Write: Herbert S. Brier W9EGQ, 409 S. 14th St., Chesterton, Indiana 46304.

TERRE HAUTE IN
JULY 18

Turkey Run Hamfest has MOVED! New location is the Vigo County Fairgrounds on Highway 41 just South of Terre Haute. There will be prizes galore, lots of flea market space under a roof, XYL Bingo, and plenty of overnight camping will be available. Presale tickets are available 4 for $5 or $1.75 ea. At the gate 3 for $5 or $2 ea. For further information or tickets write to Wabash Valley Amateur Radio Assn., P.O. Box 81, Terre Haute IN 47808.

briefs

There is resistance growing in some quarters to the ARRL repeater coordination plan. Many amateurs consider the precedent dangerous; there have been few repeater wars lately and they tend to get settled without outside intervention. In the most notorious case of the past year, the party causing the trouble (K4LSP) is the ARRL-recognized coordinator for Tennessee, though the offended repeater is in North Carolina — whose own coordinator considers K4LSP's behavior improper.

This year's ITU commemoration in May should see the first of the "N" group callsigns for domestic use. Calls like N62ITU and N38ITU are being assigned, as well as the "more conventional" ITU calls like KQ3ITU. It's not rare DX, just special events calls in the United States. While any licensee can request an ITU call, participation is somewhat limited by the $29 special license fee.

A "point of sale" CB licensing system is now going into operation. A form that comes with every new radio will permit self-assignment of a temporary callsign, that will become effective upon mailing the application (with fee) to the FCC. The postal receipt will validate the authorization.

Hopefully this system will help, not hinder, the FCC's attempts to reduce the licensing delays in the Amateur Service. While Novice licenses are being processed in about two months, some are taking longer and the percentage of lost applications is still high.

The FCC has ruled that the telephone companies may no longer prohibit interconnection of privately purchased equipment to the phone system. As of May 1, you could attach privately owned telephones and similar non-hostile devices to your telephone line without paying a special rate for an interconnect coupler.

Certain "amateur" equipment companies are doing a big business in sales of HF SSB equipment to the 27 MHz "HF" operators, who operate from 27.3 to the bottom of ten meters. The current published roster of HF International members lists about 40,000 names; bootleg registration "calls" are now well into the "HFC" series. Current amateur worry is that the "220 MHz synthesized CB transceiver" advertised by National Radio Institute in other ham magazines will become popular among CBers — even though 220 MHz CB is a dead issue.

Lloyd (W6KG) and Iris (W6DOD) Colvin have been cruising the South Pacific on a YASME Foundation DXpedition. After their successful C21NI operation on Nauru, they went to YJ8, New Hebrides, where they were denied entry because they didn't have a visa — they had been told that they didn't need one. They had to move on to New Caledonia.

SLATER MO
JULY 24-25

The Antique Aircraft and Amateur Radio Show will be held Saturday and Sunday, July 24 and 25, 1976 at the Slater Memorial Airport. Registration $1 in advance: $1.50 at the door. Buffalo burger feed Saturday night and Sunday noon. Talk-in 3963 kHz, 146.94 and 146.28/.88. For additional information and advance tickets write Dale Beilsmith WØKNF, 807 North Broadway, Slater MO 65349, (816) 529-2173.

CROSSVILLE TN
JULY 24-25

The Oak Ridge Amateur Radio Club, Inc., Annual Crossville Hamfest will be held in Crossville TN on July 24-25, 1976 at the Cumberland County Fairgrounds. Technical forums will be at the Holiday Inn on July 24 and the banquet will be at Holiday Hills Country Club on Saturday night with a Breeder Reactor Program planned. Sunday, July 25, features a picnic, flea market, raffle of many valuable prizes, and "eyeballing your friends" at the fairgrounds.

CANTON OH
JULY 25

The Tusco Amateur Radio Club and the Canton Amateur Radio Clubs are holding their Second Hall of Fame Hamfest on July 25, 1976. It will be held at the Stark County Fairgrounds, Canton, Ohio. This weekend, by the way, is the weekend of the National Pro Football Hall of Fame Football Game and Parade.

FLAGSTAFF AZ
JULY 30-AUG 1

The Ft. Tuthill Hamfest will be held July 30-31 and August 1 at Flagstaff, Arizona at Coconino County Fairgrounds across I-17 from airport. R-V and tent camping. Three days in the tall cool pines. Swapmeet, tech sessions, contests, prizes, pot luck; and exhibits. Talk-in 146.22/82, 146.34/94, 146.52 and 3992 kHz.

Handy Dandy Soldering Iron Cooler Offer

Hey baby, how does that title grab you? If you are at all like me (and you must be something like me or you wouldn't be reading this article, let alone the magazine), you enjoy finding solutions to the nagging little everyday problems found in our favorite hobby. The gadget in the photographs is my solution to a little problem that has bugged me for years. I am sure that there are many of you who have been faced with the same irksome situation: what to do with the mini-iron that you need for working on transistors and ICs, when the damn thing is up to working temperature and you need the hand to do something else.

In other words, where can you put it down? Like you, I've tried ashtrays, saucers, boards with nails, etc. Well, I finally decided to do something about it, and I don't mean buy a factory-made stand. Oh, I could have done it that way but for two reasons. First, I'm cheap! (Besides, it's more fun figuring it out for yourself.) Second, the factory-built stands only give you a place to put the pesky iron down, and I figured that if I was going to build a holder, I might just as well build one that controlled the temperature of the iron as well. As you may have guessed by now, I'm one of those lazy guys who never buys what he can build, and never builds a gadget to do one job if it can be made to do more.

A quick look at the photos will show that this is a project built one hundred percent from genuine junk box parts, and not the kind you have to buy. The base is an old 3"x5"x2" steel black crackle finished (at least it used to be) box that had been used for at least five or six other projects before finally finding respectability as the centerpiece of the workbench. Large green and red jeweled pilot lights of the 7½ W 115 V type are used in the top to show that the device is on (green), and that the soldering iron is on high heat (red), when it is withdrawn from the cradle. I didn't really need the lights, but I

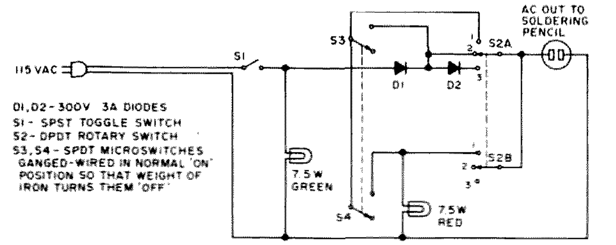

Fig. 1: D1, D2 – 300 V 3A diodes; S1 – SPST toggle switch; S2 – 2PDT rotary switch; S3, S4 – SPDT microswitches gang-wired in normal ON position so that weight of iron turns them off.

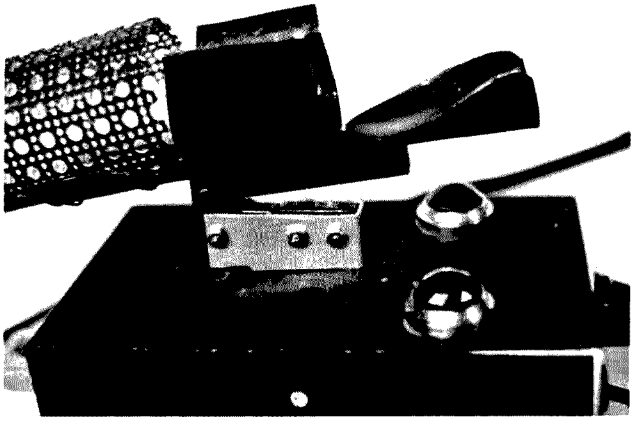

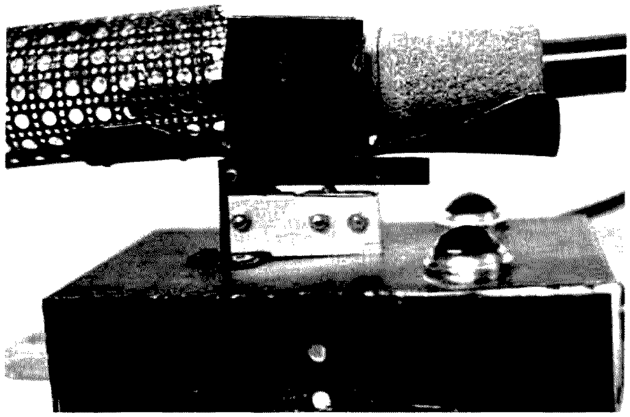

have a lot of them and they filled up two holes in the top of the box that needed filling.

The cradle for the iron is made from scrap aluminum, and the heat shield is a piece of scrap perforated aluminum sheet rolled into a tube and fastened to the cradle. This assembly is fastened to a piece of ¼" square steel rod. I drilled two holes through the cradle and the square rod and hit it with two pop rivets. The rod is now drilled at a point just aft of its balance center so that when the iron is removed it will tilt forward of its own weight. I made a little three-sided post out of scrap aluminum and pop-riveted it to the top of the box (see close-up photo); this provides the pivot point for the cradle and also a place to fasten the microswitches. In my version (I'm sure that there is no one reading this who will ever build a carbon copy), the microswitches are turned off by the weight of the iron on the cradle. As you will note in the schematic, this opens the circuit across a diode, thereby cutting down the heat on the iron when it is at rest and shorting it out when the iron is removed. Removing the iron also lights the red signal light showing that higher heat is being applied and also informing you when you don't put the iron back in the cradle properly.

Of the two switches on the front, the toggle switch controls line voltage, while the double pole triple throw rotary switch selects one of three modes. Number one position is direct line voltage or high heat. In this position the iron is connected at all times directly to the 115 V ac line. In number two position the iron is in series with a 300 V 3 A diode while in the cradle, and directly to the line voltage when it is lifted to be used. The third and last position puts the iron in series with a diode at all times, cutting the heat still further. I have found that the third position is best for soldering tiny leads close to the bases of delicate solid state devices such as HF transistors. The number two position is the one most in use on my bench, since it keeps the iron reasonably hot, but not at high temperature, and within five or six seconds after lifting it from the cradle it is up to full working heat.

The number one position could, quite frankly, have been eliminated but the switch position was there so I just went ahead and wired it in. It is rarely used because it causes tips to oxidize very quickly. The wiring diagram is, hopefully, self-explanatory. I must confess that this simple tool (gadget) is the most used addition to my bench that I have ever built. It has been in uncomplaining constant use for over two years, and only my natural proclivity for procrastination has kept me from sharing it with you before this.

This article is not an exact plan for construction, as should be obvious, nor is it intended as such. As I said in the beginning, if you are anything like me, you will have your own built-in prejudice against doing a carbon copy of anything. So just use the idea as a little prod to the grey cells and come up with your own solution. I'm sure that there are many other ways of doing this, and probably most of you can think of an even better way.

Have at it; there are too many soldering irons sitting around cold in the first place, so put them to work. ■

Perfect CW

--drive 'em crazy with the Keycoder I

Fig. 1. Keycoder I built by W9UBA.

Fig. 2. The author's version of Keycoder I.

The CW keyboard keyer described here should appeal to any amateur who wants to increase his code speed and send letter-perfect, space-perfect CW — or to anyone seriously interested in teaching or learning the code.

Although there are a lot of articles and letters in ham magazines about amateur radio clubs teaching code, the use of a keyboard keyer as a teaching aid seems to have been neglected, possibly because most such keyers are quite expensive. Keycoder I, however, can be built for \$60-\$75, *including keyboard,* and would make an excellent club project. When used as a code teacher, the keyboard keyer has the following advantages to recommend it:

- Perfect code — The learner always hears correctly formed characters
- Variable speed — Character rate is continuously variable from about 5 wpm to over 50 wpm (unlike code records or cassettes)
- Repetition — The student can practice by himself the characters that he is having difficulty with (again unlike recorded code lessons)
- Instructor need not know CW! — A unique feature — XYLs, harmonics, and other non-hams can help the novice learner without themselves knowing the code

Other technical advantages of Keycoder I are:

- TTL Logic — 9 inexpensive and readily available ICs, plus about 2 dozen discrete components, make up most of the circuit; 7 toroidal cores and another couple of dozen discretes provide an encoding matrix that would require over 100 diodes
- Rf Insensitive — With TTL ICs and only minimal bypassing, no rf problems have been experienced with the two units illustrated
- Self-contained — Power supply, logic, monitor (with tone and volume controls), and output circuit are all contained within the keyboard case
- Simple construction — A commercially available IC board makes wiring the logic easy (simple point-to-point wiring with no critical steps)

Fig. 1 is a close-up photo of the unit built by Charles H. Haut W9UBA (New Berlin WI), who is the author of this project if not of the article, and Fig. 2 shows my keyboard with a few control variations.

Keycoder I is a TTL adaptation of the Touchcoder II keyboard keyer described in the July 1969 issue of *QST*. That article contains a very good discussion of the circuit theory and of the toroidal core transformers used, so this information will not be repeated here. Our theory discussion will take you on a tour of the TTL-version schematic diagram (Fig. 3). For convenience of discussion, the schematic is separated by dashed lines into the following six areas representing functional blocks: (1) dot generator, (2) dash generator, (3) shift register, (4) encoding matrix, (5) monitor, and (6) output stage. The discussion that follows will be so divided also, with some necessary overlapping. On the schematic diagram, the logic state H ("1") or L ("0") is shown for the output of each IC. These states are for static conditions, when no character is being generated.

Dot Generator

IC1 is a 555 integrated circuit timer set up as a triggered multivibrator. The frequency of the multivibrator (and hence the code speed) is determined by the

values of R1-R3 and C1, and is adjustable by means of R2. The duty cycle is 50% for all practical purposes, thus providing dots and character interelement spaces that are equal. (Of course other R and C values can be substituted. Those on the schematic are the ones in W9UBA's unit; I used R1 = 1k, R2 = 50k, R3 = 15k, and C1 = 2.2 uF, with equally satisfactory results.)

R4, R5, and CR1 are bias components that are necessary to make the first dot the same length as following ones. This is because normal timer operation charges and discharges C1 between 1/3 and 2/3 vcc. However, on the very first cycle, C1 is discharged, and has to charge from 0 volts to 2/3 vcc. The resistors, which are merely a voltage divider across the power supply, maintain a bias voltage on C1; CR1 prevents interference with the normal triggering of IC1.

The output of the dot generator (pin 3) is routed to both the output circuit and monitor through two sections of IC4 (NOR gates); the first section is a summing gate (discussed later), and the second section disables the output (and monitor) for the duration of 3 dot lengths at the completion of each character, to provide automatic character spacing.

Dots are generated when pin 6 of IC1 goes low, which occurs only when pin 6 of IC3 goes low.

Dash Generator

As with other keyers (both keyboard and manual), Keycoder 1 forms dashes by filling in the space between two successive dots, thus producing dashes exactly 3 units long. The circuit action is as follows: FF8 is a "D" type flip flop that clocks on the rising edge of pulses applied to pin 11. When no dashes are called for, pin 3 of IC3 applies a "1" to the data input (pin 12) of FF8, and the Q output of this flip flop is high and the $\overline{Q}$ output is low. FF8 is clocked each time a dot is generated but does not change state as long as the IC3 output is high. When a dash is required, pin 10 of IC4 goes high, causing pin 3 of IC3 to go low, and FF8 is readied to toggle when it is clocked. For a dash to be formed, two dots are generated. The first dot is passed through to the output but also clocks FF8. The $\overline{Q}$ output of FF8 then goes high and holds the summing gate portion of IC4 open after completion of the first dot. After arrival of the first dot, pin 1 of IC3 also went low, readying FF8 to toggle back to its static state. FF8 is clocked by the second dot, and its $\overline{Q}$ output goes low again, but the second dot now holds the summing gate open. Hence, the summing gate is open for a period of two dots and the space between them, and a 3-dot-length dash is formed.

This same sequence of events takes place at the completion of each character to automatically provide a 3-dot-length space between characters, but this terminal dash is made silent by applying a high to pin 12 of IC4.

Shift Register

As shown in Fig. 3, the shift register portion of the schematic consists of "D" type flip flops FF1 through FF7, two sections of a triple 3-input NAND gate (the third section isn't used), the remaining two NOR gate sections of IC4, and two gates of a quadruple 2-input NAND gate IC (the fourth section isn't used). In this mechanization, the 3-input NAND gates serve an OR function, one

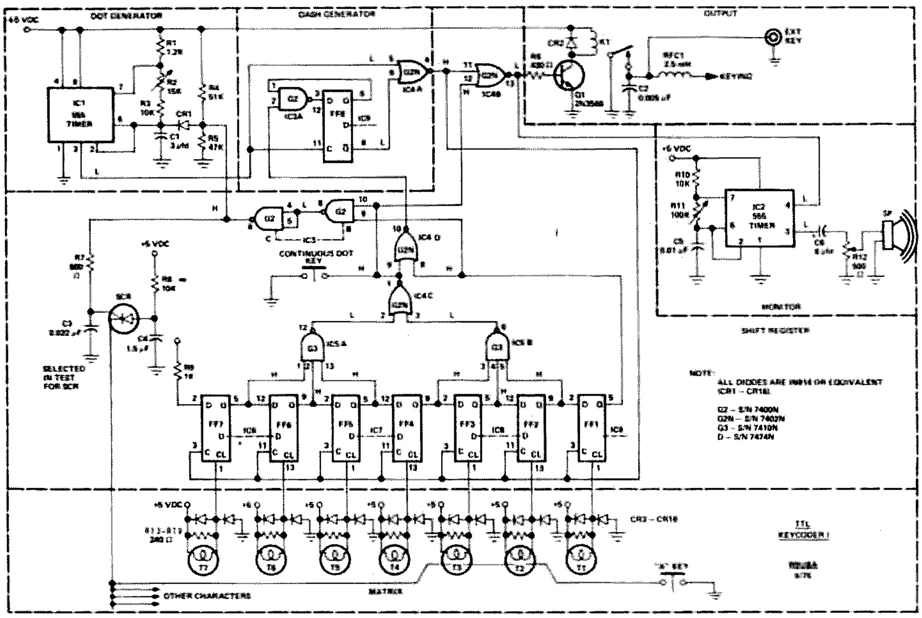

Fig. 3. Schematic.

section of IC4 is used as an AND gate, and pins 4, 5, and 6 of IC3 are really only an inverter, so things aren't entirely as they seem.

The flip flops are all "D" types, and are packaged two per IC. Note that the second flip flop of IC9 is the FF8 previously mentioned. Only the Q outputs (pins 5 and 9) are used, and these are a logic high in the static condition. For our purpose, the flip flops are "set" (Q = "0") by applying a low to their "Clear" terminals (pins 1 and 13). Shifts occur from left-to-right only.

With the foregoing in mind, let's leave the hardware mechanization for a bit and refer to the Character Generation Table (Table 1). Here, the "X"s in the horizontal rows represent the dashes in a character, the "X" furthest to the left is a "silent dash," and the blank spaces to the right of the silent dash represent dots. Although data is shifted left-to-right, we "read" Morse characters in this table from right-to-left. For example, in the row for the letter "P", starting from the extreme right we see a blank space which represents a dot. Moving to the left we find two "X"s, which we know are dashes, followed by another blank space for a dot, and finally another "X" (which is the silent dash to separate this character from the next). In terms of the hardware, the "X"s represent the flip flops that are simultaneously set when a keyboard key is struck, and also the toroidal cores that must be strung to generate that character.

The character generation scheme, which was originally proposed by James B. Ricks W9TO (Evanston IL), has three rules:

1. If only one flip flop is set, a number of dots will be generated, the number being one less than the number of the flip flop set. For instance, in the row for "S", only one "X" appears, in the column headed FF4; therefore 3 dots will be generated.
2. If FF1 *and* any other flip flop are set, a dash will be generated.
3. If only FF1 is set, a silent dash is generated.

As each dot or dash is completed, all entries in the appropriate row of the table are shifted one column to the right, and another of the three above rules is applied. For the letter "B", initially the conditions for rule 2 are met, and accordingly a dash is generated; after one shift to the right, rule 1 applies, and three dots are generated; these three dots produce three more shifts, after which rule 3 comes into effect and the character is completed, followed by a 3-dot-length space.

Returning to the schematic, observe that the static state for the flip flops is for their Q outputs to be high. This results in the other gates in the register being forced to the logic states shown, ending up with pin 6 of IC3 being high and the dot generator disabled. Through a process to be described later, one or more of the flip flops is set each time a key is struck. The resulting lows on the flip flops cause the outputs of one or both sections of IC5 to change state and, in turn, pin 1 of IC4 and pins 8 and 6 of IC3, thus starting the dot generator. If pin 5 of IC9 goes low and the Q output of any other flip flop also goes low (rule 2), pin 10 of IC4 will go high, and a dash will be generated; otherwise a dot will be formed. The dot or dash causes pin 4 of IC4 to go from a high to a low. This pin is connected to the clock inputs (pins 3 and 11) of the shift register flip flops, but a high-to-low transition does not affect a "D" type flip flop. However, when the dot or dash is completed, pin 4 of IC4 again goes high, and the low-to-high transition does clock all of the flip flops causing a right shift. That is, the Q output of each flip flop assumes the logic state that its left-hand neighbor had before the clock pulse. The resulting new set of Q outputs now initiates another dot or dash which, in turn, produces another clock pulse to shift the register to the right again, and so on until only the output of FF1 is low. This is the condition (according to rule 3) to generate a silent dash. What actually happens here is that FF1 turns on the dot generator, but since the other flip flop outputs are all high, pin 1 of IC4 is high and provides the output inhibit signal to pin 12 of IC4. Note that the silent dash creates another clock pulse that shifts the "1" output of FF2 into FF1, thus ending the character cycle and restoring the static condition.

In addition to starting and stopping the dot generator, pin 6 of IC3 also activates the gate of the SCR that provides current drive to the keyboard encoder circuitry. Therefore, the keyboard is locked out during character generation, but is automatically re-enabled as soon as the character is completed. This feature also provides automatic character repeat: A character is repeated, with 3-dot-length spaces between, as long as a key is held down.

This is a fine operating feature for sending words with double "o"s and double "l"s, etc., but is not so hot for sending double "e"s at high speed. If desired, automatic repeat can be disabled by reducing the drive on the SCR.

Note the "continuous dot" key connected between pin 1 of IC4 and ground (this is the switch labeled "DOTS" in Fig. 2). This is depressed and held down while adjusting the SPEED control to initially set the keyer to the desired code speed. The continuous string of dots resulting from holding down this switch represents the maximum sending speed for a given SPEED control setting. Holding down the "E" key also produces a string of dots, but with 3-dot-length spaces between each one.

Keyboard Encoding Matrix

Toroidal core transformers, driven by an SCR, are used for encoding keyboard contact closures to set the shift register flip flops in accordance with the Character Generation Table. These transformers are made by winding 10 turns of #30 enameled wire around half inch diameter powdered ferrite cores. The windings are equally spaced around the circumference of each core, but the spacing is not at all critical (see Fig. 4). Only cores with high permeability, such as those in the Parts List, should be used. The "one turn primary" of the transformer is simply a length of the same type of wire passed through the center of the cores appropriate to the character to be formed (per the Character Generation Table). One end of this primary is soldered to the keyboard contact of a given character, and the other end to the cathode of the SCR. There is, of course, one such primary for each of the 44 CW characters in the table, and several pass through each core. With #30 wire the cores don't get too crowded, and there is no effect on the cores by wires that pass around the cores but don't go through them (see close-up photo of the logic board, Fig. 5).

One end of the secondary winding of each transformer is connected directly to Keycoder's +5 V dc regulated power supply, and the other end to the "Clear" terminal of each shift register flip flop. When the SCR fires, a high current pulse passes through the one turn primary connected to the key pressed. This pulse induces a very short duration high voltage (up to 15 V) pulse in the secondaries of the cores it passes through. These pulses are polarized in opposition to the +5 V applied to the secondaries and drive them to ground potential, thus setting the flip flops to which they are connected. The resistor across each secondary is for loading to suppress transients, and probably wouldn't really be needed (but is cheap insurance). Its value isn't critical. The diode in parallel with the resistor clamps the voltage to +5 V to prevent possible damage to the flip flop from too high a voltage spike. This probably isn't actually required either, but W9UBA and WA9VGS are cautious fellows. The diode in series with the clamping diode to ground prevents the flip flop "Clear" from being driven below ground (negative voltages should never be applied to TTL ICs).

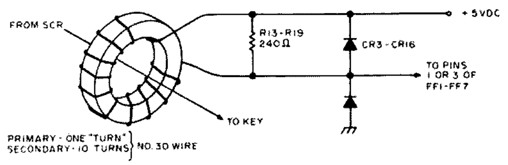

Fig. 4. Toroidal core transformers used for encoding.

The SCR circuit works like this: C4 is charged up to the power supply voltage through R8. The gate of the SCR is open since pin 6 of IC3 is high, but current cannot pass because the keyboard key is open, breaking the cathode connection to ground. When a key is struck, the circuit is complete and C4 discharges almost instantaneously (the actual discharge time depends upon the time constant of C4-R8). This discharge produces the high current pulse to fire the core secondaries and set the flip flops. The instant a flip flop is set, pin 6 of IC3 goes low, closing the SCR gate, and C4 begins to recharge for the next character. The closed gate ensures that the keyboard is locked out until the character being generated is completed and IC3 pin 6 goes high again. C3 is simply a filter capacitor to prevent transients from triggering the SCR.

Monitor

IC2 is also a 555 IC timer connected as a triggered multivibrator. The bias components used in the dot generator are not necessary here since the IC is oscillating at audio frequencies. None of the R or C values are critical and can be chosen to suit your preferences or what you have available. With those shown, the monitor produces

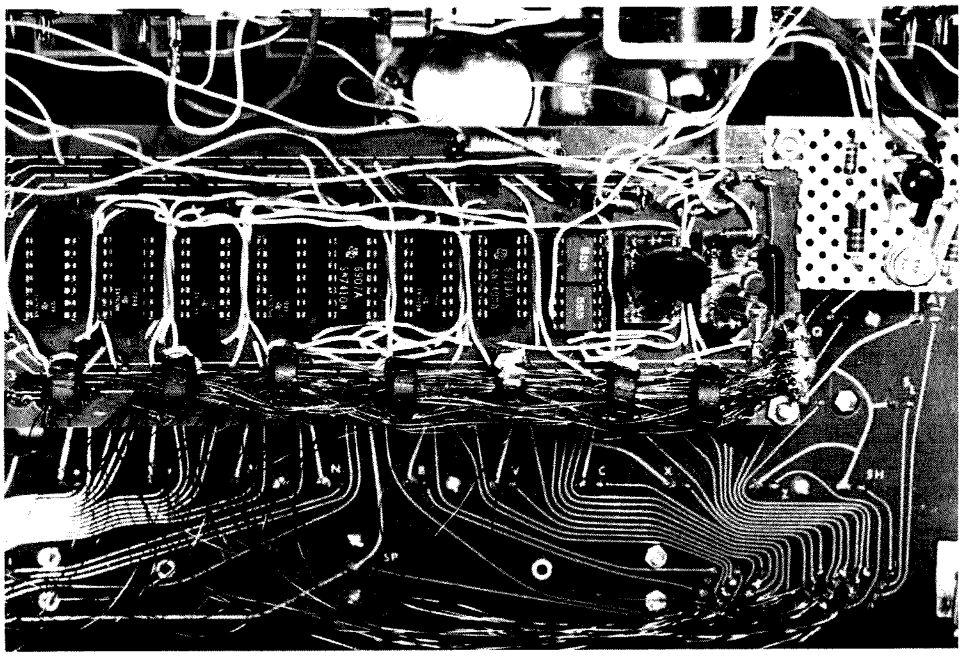

Fig. 5. Close-up view of the logic board.

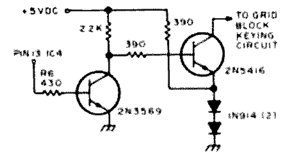

Fig. 6. Transistor keying circuit for Keycoder I.

tones from about 50 Hz to several thousand Hz, adjustable by R11. Of course R11 can be a fixed resistor if you'll settle for a single tone. C6 and R12 form the simple but adequate volume control. When set at its low end, R12 completely silences the monitor, and at the high end the IC will drive a 2"-4" speaker to a volume adequate for a medium-sized room. In the dot generator, the "Reset" terminal (pin 4) was tied to +5 V dc and the IC was triggered on and off via pin 2. In the monitor, however, we switch IC2 on and off via pin 4, since our driving signal (pin 13 of IC4) is low in the off state and high in the on state.

If Keycoder I is to be used exclusively with rigs that have a sidetone, obviously the monitor could be eliminated completely, but for the small number of components involved it's nice to have the unit completely self-contained for code practice without connection to a rig.

Output Circuit

The TTL output of Keycoder I can be used to drive either a keying relay, as shown in Fig. 3, or a PNP power transistor, if you can find one with ratings adequate for the keying circuit of your rig. (We found such transistors very hard to find; W9TO very kindly provided a list of suitable transistors, with their voltage ratings, which is appended to the Parts List.)

In the relay circuit shown in Fig. 3, Q1 can be any small NPN audio transistor (I used a HEP 728 with R6 = 2200 Ohms). The value of R6 can be changed to optimize the base drive if you substitute for Q1. For K1 I used a Griggsby-Barton 831C-2, which is packaged in a 14-pin DIP package and includes a protective diode (CR2). This relay is both small and completely silent, but is relatively expensive (about $5), and its contacts will only handle about 125 mW. However, this was adequate to key my Kenwood TS-520 transceiver (keying current 10 mA at 12 V). A better choice would be a surplus reed relay, such as listed in the Parts List. These are quite inexpensive (2/$1), and will handle 500 mA or better. W9UBA has used one of these relays to key his Drake T4X transmitter, Hallicrafters SR160, and several Heathkit rigs, without any difficulty.

C2 and RFC1 are for filtering any rf out of your rig's keying circuit line, and may or may not be needed depending upon how "clean" your rig is. Without either filtering component in the circuit I "froze" the contacts of one IC relay after several hours of troublefree sending, but have piled up several dozen operating hours without any relay problems after adding C2 (I still have no choke in the keying line).

Fig. 6 shows the circuit for transistor keying. Again, Q1 can be any NPN audio transistor. W9UBA has both a reed relay and the transistor shown in Fig. 6 connected in parallel in the output of his keyer, and switches back and forth between the two. Most of his on-the-air contacts have reported no discernible difference between the relay and transistor keying.

Construction

The keyboard unit is enclosed in a rugged and handsome case that is spacious enough for all of Keycoder's component parts. It was obtained from Meshna Electronics (#SP-153-L) for $35, plus shipping charges on 7 lbs. from Lynn, Mass. It is built on a heavy cast iron frame, and is trimmed in leatherette and imitation walnut grain sheet metal. The keys are magnetic reed type, very smooth, with about 3/16" travel. An added bonus in this assembly is the 10 rectangular switch positions (as seen in Fig. 1). Five of these are dummies – the plastic switch caps are in place but there is no switch beneath them – and I removed them and used the space for mounting 3 control pots (Fig. 2). Four of the other 5 switches are momentary action DPDT switches, and the fifth (labeled "PWR" in Fig. 2) is a DPDT Push-On/Push-Off switch. The two switches on the extreme right have screw-base "grain-of-wheat" light bulbs installed in sockets inside the translucent caps. I wired one of these, through a 20 Ohm, 1 Watt dropping resistor and the second set of "PWR" switch contacts to the power supply, to serve as an on-off indicator. W9UBA accomplished the same purpose by installing a red LED in a hole drilled in one of the switch caps (Fig. 1). There are also plenty of unused key positions on the keyboard (SPST), so you should be able to mechanize any control setup you like without additional switches.

There is a diode matrix circuit board just beneath the bottom cover of the key-

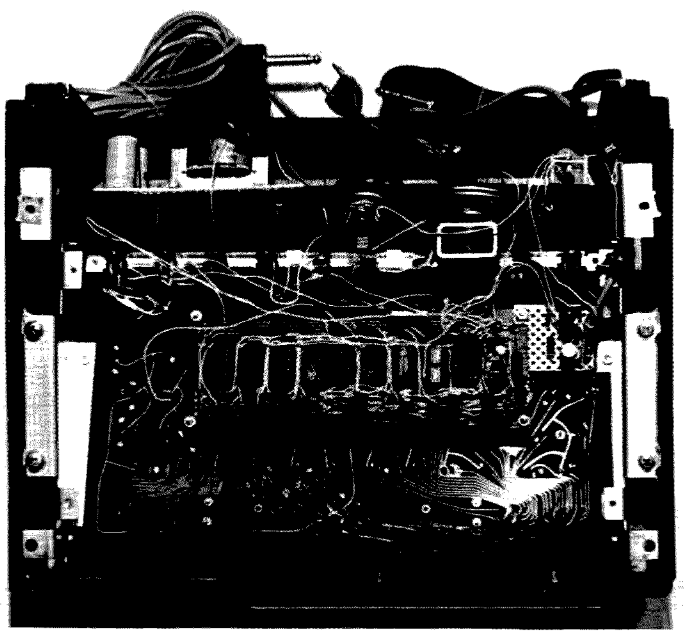

Fig. 7. Interior of W9UBA's Keycoder I.

board case. This board contains about 160 diodes and several dozen 33k resistors that can be added to your junk box (although the leads are awfully short). This board is attached to the case with a couple of screws and two multiple-lead ribbon cables that are easily removed. Beneath this discarded diode board is the key contact board, with all of the key contacts nicely labeled. Half of the foil patterns from the key contacts go to solder terminals grouped together at the bottom left-hand side of the board, and half lead to similar terminals at the bottom right. I soldered the core primary wires directly to the key contacts wherever they were on the board, while W9UBA made these connections to the bottom sets of terminals, resulting in shorter wire runs and a neater appearance (see Fig. 7).

The 9 integrated circuits, the SCR, and their associated discretes were all mounted in DIP sockets on a Radio Shack Universal Display Board (P/N 277-108). This board is predrilled for 10 14-pin DIPs, and etched with solder pads for the DIP connections and 8 separate buses running the length of the board, 4 on each side of the DIP patterns. These buses were used for +5 V dc, ground, SCR common, and the flip flop clock line. We both used #22 hookup wire for all connections; W9UBA ran his wires on the top side of the board while I made most of my connections on the foil side. Either way, this board saves a lot of building time compared with vectorboard construction or laying out and etching a PC board. The board measures about 2½" x 6¾" and costs $3.

Since the 555 ICs have only 8 pins, both of them can be mounted in one 16-pin socket; the leftover sockets can then be used for mounting the SCR and 555 discretes. The toroidal core transformers and their diodes and resistors are also mounted on the board, beneath the row of ICs (as seen in Fig. 5). The cores are wound and soldered into the circuit, but the leads are left about ¾" long. Any one of the primary wires connected to the SCR is then strung through each core before it is mounted and the wire is grounded; if nothing happens, the core polarity is incorrect and the long leads permit it to be turned 180°. When a core is operating correctly, it is glued to the board with a drop of Duco cement. Stringing the primary wires through the cores will be easier if the cores are mounted so that their openings are in a reasonably straight line.

The values of R7-C3 and R8-C4 required some juggling to get reliable SCR operation. The most severe test of SCR and core operation is generating the figure "0", since 6 flip flops have to be set simultaneously to produce this character. If you have difficulty generating "0"s, or with repeat operation, vary the values of the above components, and/or try connecting R8 to the unregulated output of the power supply to get a higher voltage and hence more current.

All the integrated circuits were bypassed with .01 uF disc capacitors from +5 V dc to ground, at the buses right opposite each IC. These capacitors are visible at the top of the board in Fig. 5. In addition, each side of the power supply transformer primary is bypassed to ground with .001, 400 volt capacitors. The all-metal, completely enclosed keyboard case provides good shielding and also contributes to the lack of rf interference.

Fig. 3 does not show the power supply, since the keyer's power requirements are reasonably uncritical and the builder will probably wish to fabricate his supply with whatever parts he has available. The Keycoder draws about 100-125 mA and the +5 V should, of course, be regulated. We decided to build our supply based on the Radio Shack 5 Volt Regulated Power Supply PC board (P/N 277-102, price $1.49). This board measures only 1¾" x 3¾", and can accommodate whatever parts you have or whatever circuit variations you wish to make. Fig. 8 is a schematic of the power supply with the parts values as specified by Radio Shack. In this configuration, the supply is rated at 1 A. The power supply is mounted in the upper left-hand corner of the case in W9UBA's unit, as shown in Fig. 7.

Parts List

IC1-IC2	555 Integrated Circuit Timer
IC3	Quad 2-input NAND gate (SN 7400)
IC4	Quad 2-input NOR gate (SN 7402)
IC5	Triple 3-input NAND gate (SN 7410)

*Germanium transistors, all others silicon.

Referring again to Fig. 7, the output transistor and its driver and associated resistors are mounted on a scrap of vectorboard just to the right of the logic board, and the reed relay is just above the vectorboard, mounted to a partition added to the enclosure. The monitor speaker is mounted on the other side of this partition (beneath and to the left of the relay).

The volume, tone, and speed control potentiometers have to be miniature types if they are to fit in the area shown in Fig. 2. The pots are mounted to a small piece of thin aluminum sheet, which is held firmly in place when fitted between the keyboard assembly and the outer case. W9UBA used full-sized pots mounted under the row of keyboard switches, as shown in Fig. 1. Also note in this photo the sub-miniature thumbwheel type pot mounted in a rectangular hole cut in the switch cap (extreme left-hand one).

The speed control range can be increased at either the low speed end or the high speed end, or both (by altering the values of R1-R3 and C1), but resolution will become poor if too large a speed range is attempted, and it will be difficult to accurately repeat a given speed setting. Two switch-selected pots could probably be used to obtain a greater range of speeds without sacrificing resolution. Audio taper pots should be used for speed, tone, and volume control.

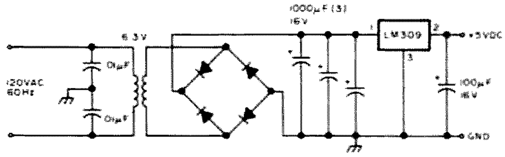

Fig. 8. Schematic of +5 V dc regulated power supply.

Operation

Both W9UBA and I have had several compliments on having a "gud fist" before informing our contacts that we were using a keyboard keyer. More important, we estimate that our CW speed increased 5-10 wpm within 3 weeks after having our Keycoders on the air. We believe this is due, in part, to hearing perfect code as we are sending, and in part to the natural tendency to send faster, since it's so easy (thus unintentionally inviting a higher speed QSO).

It takes very little practice to get the rhythm of typing on a keyboard keyer, and you don't have to be a good typist. Once you know where the characters are on the keyboard, 20 wpm seems incredibly slow, even for a "hunt-and-peck" typist. A good typist must learn to allow enough time for long letters, such as "q" and "y", to be completed before hitting the next key, and a shorter time for letters like "e" and "i", but with just a little solo practice you'll be ready to go on the air. It was originally thought that a 2 or 3 character memory, and/or a space bar mechanization, would be added to Keycoder I, but operation without these features has been so good that it has been decided to forego this additional circuitry.

In addition to W9UBA's design work, moral support, encouragement, and help with parts procurement, the assistance of three others should be acknowledged: James D. Stenseth K9CML (Franklin WI) and Mr. Ray Young both helped with design details, and on-the-air contacts and letters from W9TO were much appreciated. ■

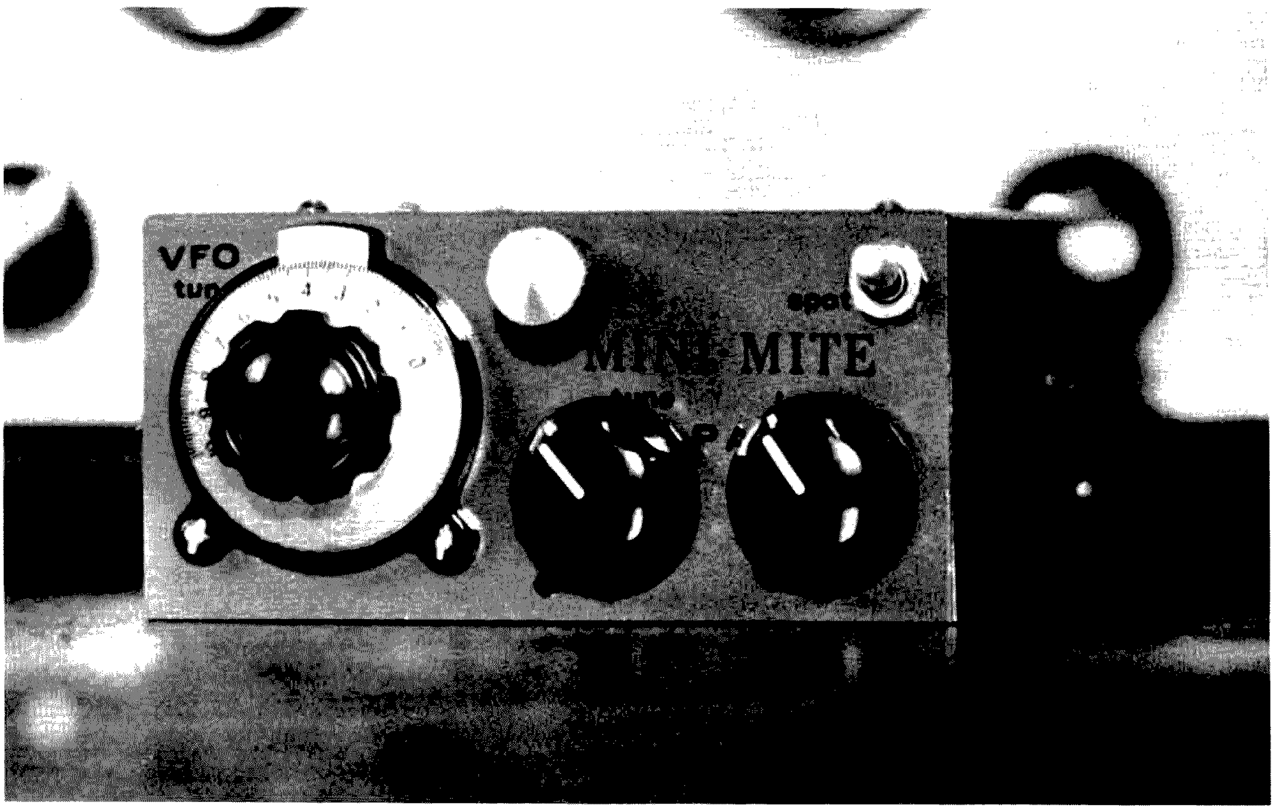
The Mini-Mite Allband QRP Rig

--runs a mighty seven Watts

Operating QRP is fun. Operating portable is fun But, operating QRP with the kind of inefficient antenna systems sometimes encountered in portable operation is no fun at all. Sure, with a good matchbox, you can load a barbwire fence, or a set of bedsprings, but those aren't the best radiators in the world, and the puny little 100 mW QRP rigs will have a hard time getting across the street. While facing this dilemma, I decided someone should invent the perfect QRP rig, one that is small enough to be super-portable, low powered enough to run off a lantern battery, and gutsy enough to make some noise across town into the



The Mini-Mite, a "kilowatt" among QRP rigs, runs 7 Watts peak power for cutting through the QRM and clearing the frequency for the little QRP rigs.

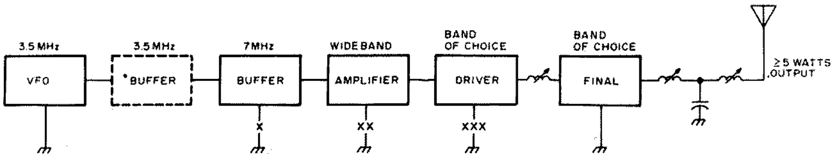


*Fig. 1. Block Diagram. The Driver and Final stage tuned circuits are selected for the band of your choice. Note they operate straight through on all bands for maximum efficiency. *This buffer is optional; it may be added to reduce vfo pulling — this is especially helpful when the unit is used with break-in keying. The keying points (shown by "X") have various advantages and disadvantages. See the text for a complete discussion.*

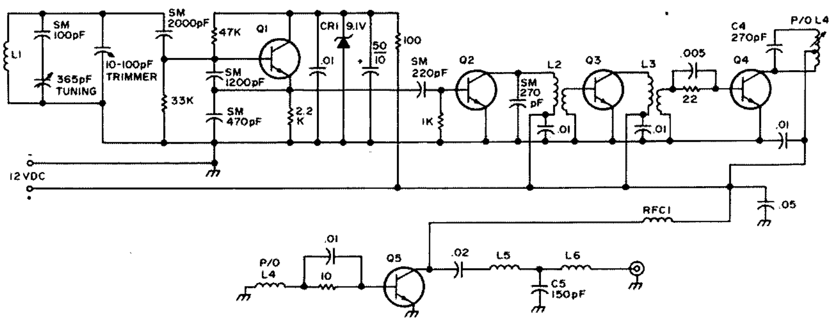

Fig. 2. Schematic Diagram. Coils are discussed in the text. All values in pF unlesss otherwise stated. Resistors are given in Ohms and are all ½ Watt carbon types.

average portable antenna.

Since I am the only inventor I know, I had to call upon myself to come up with this "wonder-rig." And (if I do say so myself) I did a pretty good job. The final outgrowth of the requirements is a muscle-powered mini-watter I call the "Mini-Mite." Now you can build yourself a Mini-Mite for less than twenty dollars. It is the perfect Novice rig with its 7 Watts dc input; it is the perfect standby rig for the oldtimers; and darned if it's not the answer to the QRP nut's portable operating dreams. The rig is vfo controlled (why be old-fashioned?), it runs a solid five Watts, can be held in one hand, and has a complement of controls you would expect to find only on more expensive rigs. You can build it for any or all the bands of your choice, 80-10 meters. And, finally, if you insist on staying around the one Watt level with your QRPing, you can leave out the final for a dandy low-power "low power" transmitter.

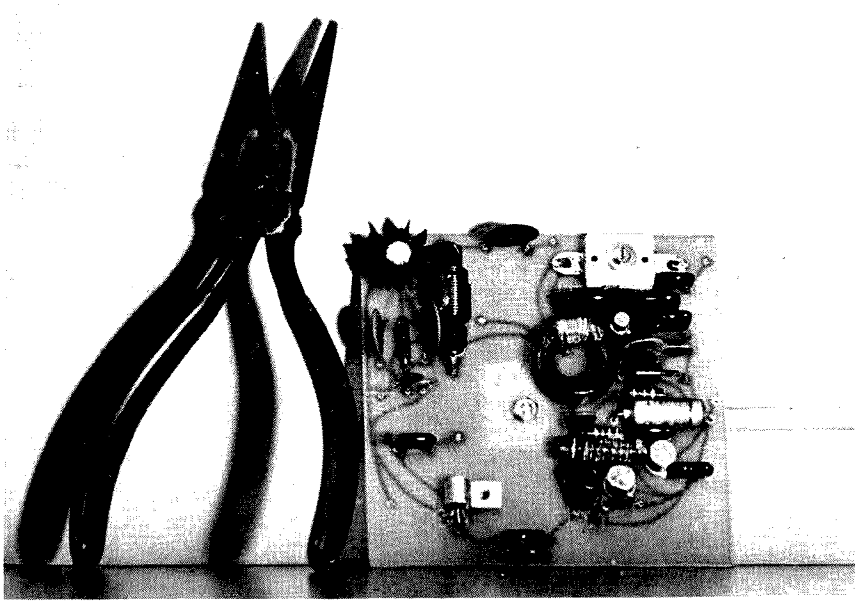
Fig. 1 is a block diagram of the Mini-Mite. The rig is pretty straightforward as far as using conventional circuits. Once you are into the schematic you will see some unique features that save space and money in the rig. The vfo circuit is very stable and you have a choice as to using a bipolar vfo or an FET vfo (schematics for both are given). The buffer shown in dotted lines is optional; it provides greater immunity to pulling as the rig is tuned and keyed. This option is a must for the operator who wants "everything" in his rig, or who is interested in using break-in operation. The buffer stage (solid lines) uses a broad-tuned low Q circuit which resonates at 7 MHz, but passes sufficient 80 meter signal to allow the rig to operate multi-band. The buffer operates class A and runs at fairly low power. The amplifier stage is a wideband outfit which delivers the first real power in the rig; you could use the amplifier output as a transmitter output, except that it is rich in harmonics. The driver serves two purposes; one, of course, is to provide power drive for the final. The other use for the driver is to select the harmonic of the vfo signal that will be used to transmit. The driver tuned circuit is comparatively medium Q. The driver tuned circuit alone does not provide adequate harmonic attenuation, so if you decide to build the "QRP" Mini-Mite you may leave out the final stage, but you must keep the final tuned circuit because it provides the necessary harmonic rejection. For normal QRP "plus" operation the driver feeds the final which in turn generates the so-called high-power output signal. The final output circuit is one of those unique circuits I mentioned, it uses slug-tuned forms to provide the tune and load controls. The output will easily load into 50-70 Ohms and a little more. Harmonic output at the final is very low and when the rig is properly tuned the output signal is very clean.

Fig. 2 is the schematic of the complete Mini-Mite. Some of the interesting features are the coils. You may pillage the junkbox to see what you have, or you may buy three sets of the units given in the parts list. For the vfo coil, L1, the buffer coil L2, and the rather unique output transformer L3, you use only the slug from a coil. You do not use the coil form itself. Coils L4, L5 and L6 use the complete slug-tuned form as these three coils are tuneable and must have some means of adjustment.

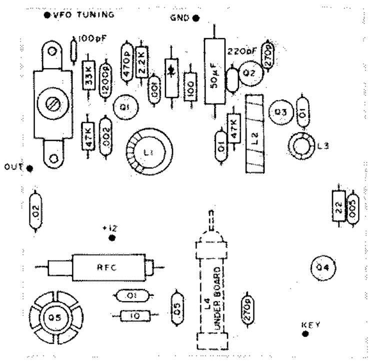
Construction

I am the biggest booster of perfboard construction when only one of anything is built, although the photos show a printed circuit board for building more than one of the units. The coils are available from Radio Shack and are sold two to a package at slightly over a buck.

The vfo in the pictures uses an Amidon T92 toroidal coil, but other units have been



Here is the Mini-Mite PC board.



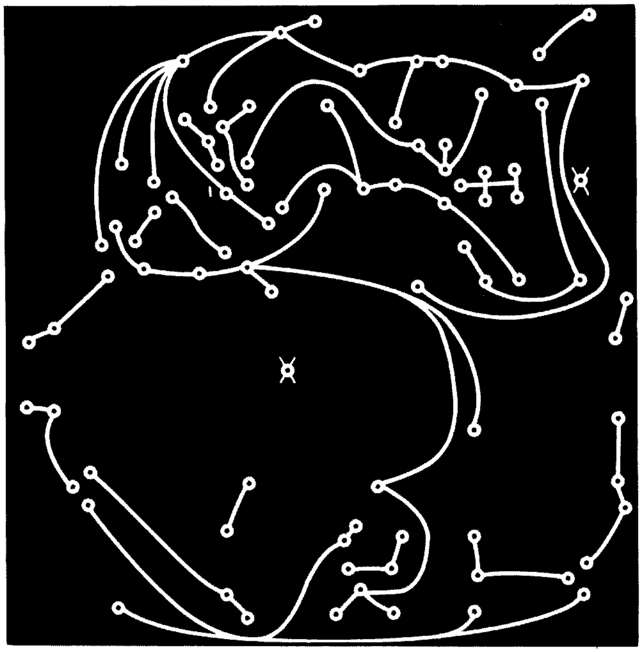


Fig. 3. PC board layout, top and bottom views.

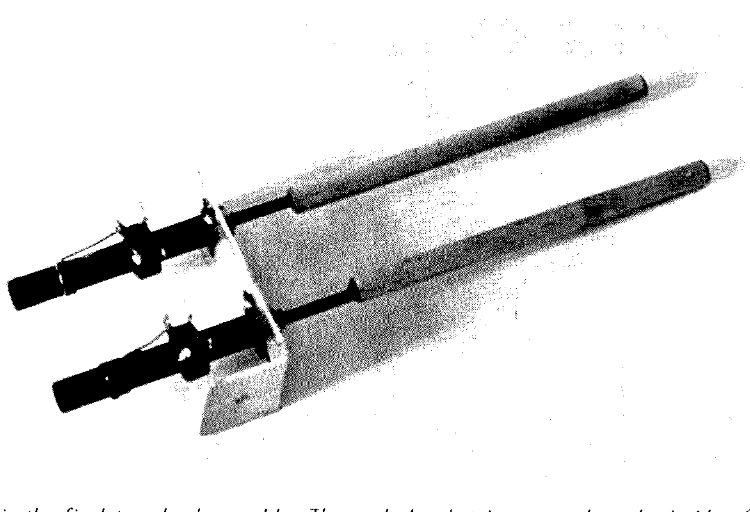
built using the slug as described and they offered comparable performance. Although you could construct the vfo in a separate shielded box, it is provided for right on the PC board. Fig. 4 gives the schematic for the alternate FET vfo. Both vfos tune with a 365 pF tuning capacitor and use a 100 pF fixed capacitor in series to limit the tuning range. Vfo tuning is linear for the bottom 100-200 kHz of the band and then becomes non-linear (but usable) over the remaining portion. This is generally acceptable, since most people will just put the linear portion in their favorite part of the band anyway. The FET vfo will provide more stability than the bipolar unit, but it will run the cost of the rig up a little since the same transistor that is used in the vfo can also be used as the buffer, amplifier and driver stage. Also, you may get slightly less drive to the buffer using the FET.

The buffer stage provides a compromise between actually isolating the oscillator and giving a little power output. That's why there is an alternate buffer, to provide isolation and little or no gain. Fig. 5 shows the alternate buffer; the circuit uses no tuned circuits and is merely stolen from the Radio Amateur's Handbook. The Mini-Mite buffer is straightforward and uses the slug form previously described (and as can be seen in the photos). It should resonate around 7 MHz if you want to check your work with a grid dip meter. The windings are wide-spaced along the entire slug, not wound closely together. Hold the windings in place with a little Q dope, or equivalent. The output link is wound on the cold end (Vcc side) of the coil and provides impedance matching for the amplifier stage.

The amplifier runs class B and there are no biasing resistors to worry about. It is very simple: The input goes on the base, the emitter is grounded, and the collector gets +12 through the output transformer L3. L3 is left untuned and serves to couple wide-band, harmonic loaded output to the driver stage. The transformer itself is a twist on the toroid. It is fabricated from a high-permeability coil slug that has a hole all the way through it. Either grab one from the junk box, or drill a hole (lengthwise) the rest of the way through the Radio Shack slug after the tuning screw is removed. This stage provides enough power to dimly light a #47 bulb connected across the secondary. The power is to put some kick in the driver stage and if not for all the harmonics, you could use this output for a QRP transmitter all by itself.



Here is the final tune-load assembly. The angle bracket is mounted to the inside of the cabinet and the wooden dowels serve as tuning shafts to the front panel.

Harmonics are taken care of in the driver to a great extent. The higher power drive from the amplifier is used to drive the driver into class C for most efficient operation. When the driver operates, current flows through the 22 Ohm resistor, setting up a reverse bias that causes the stage to operate class C. The resistor is bypassed for the ac signal. The tuned circuit in the driver is close to that in the buffer, except that the coil is tapped to yield a higher Q with the higher power output. Harmonics at this stage are nothing like at the amplifier stage, but to use this stage as the QRP rig, you will have to couple the output tank circuit to get an acceptable signal. The tuning of the driver coil is accomplished by a wooden dowel shaft extension. The dowel should be approximately 4½ inches long to reach the front panel from its position under the PC board. As can be seen in the photos, the coil mounts on the PC board directly. An angle bracket is satisfactory mounting.

The final stage will run a theoretical 7 Watts dc input. The output circuit is a "T" network with slug-tuned coils used as the output tuning and loading controls. The final output transistor is rather expensive, but is hardy and generally works well in

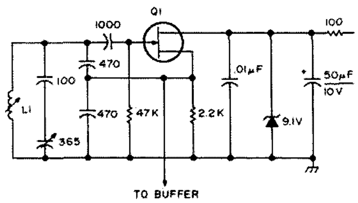


Fig. 4. Alternate FET vfo. Capacitors and resistors in pF and Ohms unless otherwise stated.

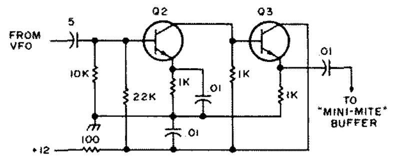

Fig. 5. The optional buffer is used in conjunction with buffer in transmitter to provide better isolation for break-in operation or for when some pulling of the vfo cannot be tolerated.

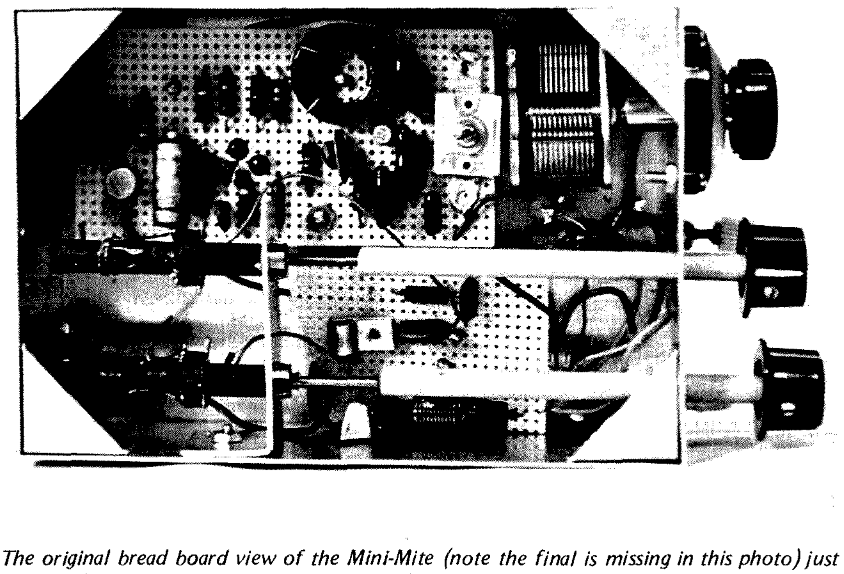
Table 1. Coil/capacitor data (final values will need trimming).

these applications. It will operate at frequencies in excess of the 30 MHz encountered in the 10 meter version of the Mini-Mite, so it is a pretty good choice until research proves the existence of a better all-around transistor. The rf choke used in the final is a high-current jobby. A conventional rfc has too much dc resistance and limits the output power stage can run. Wind forty turns #18 en. close and in 2½ layers directly on one of those slugs.

Table 1 gives values for coils and capacitors to be used for multi-band operation. You may wish to switch in the coil/capacitor combinations, or do some experimenting with winding multiple coils on the same form. Some of the problems are that the coil/capacitor combinations are sympathetic to harmonics and you may get false loading. But, as long as the Q is high enough, you could make each band peak at some different setting of the slug in the coil form. This helps eliminate the problem. Also, remember to use shielded solenoid inductance formulas because the overlapping coils act as shields and change the normal calculations. The cost savings of this system would be significant. This could be our answer to the old familiar tapped coil setups in tube-type rigs.

The final tuning coils are mounted on a piece of angle aluminum as shown in the photos. Each slug-tuned coil has a wooden dowel extension approximately 3-3/4 inches long. The dowels used on all the tuning setups are standard 1/4 inch diameter units. They are epoxied to the tuning screws. When the coils are tuned to minimum inductance, the knobs stick out from the front panel a little way. You can build the unit, tune it, then cut off the dowels at the right approximate length to keep the knobs from sticking out too far.

Construction is not too critical. The Mini-Mite is built in a 6x4x2 inch chassis (LMB #642); you may add the bottom plate which is available for this chassis. The circuit board is a very tight fit in the box. In order to get the circuit board in, it will have to be slid into place before the tuning capacitor is mounted. Then push the circuit board back all the way against the back wall of the box. This should leave enough room to insert the tuning capacitor. Hold the capacitor in place by means of its mounting holes and screws, then slide the PC board forward into its mounting place. The PC board is held away from the chassis on 1/4 inch spacers. Mount the spacers in place, tighten nuts over the mounting screws, and then the PC board is slipped into position and more nuts are placed over the mounting screws. This allows you to remove the PC board without the hassle of always fumbling to find a way to hold the spacers in place while you stick the mounting screws through them and the PC board.



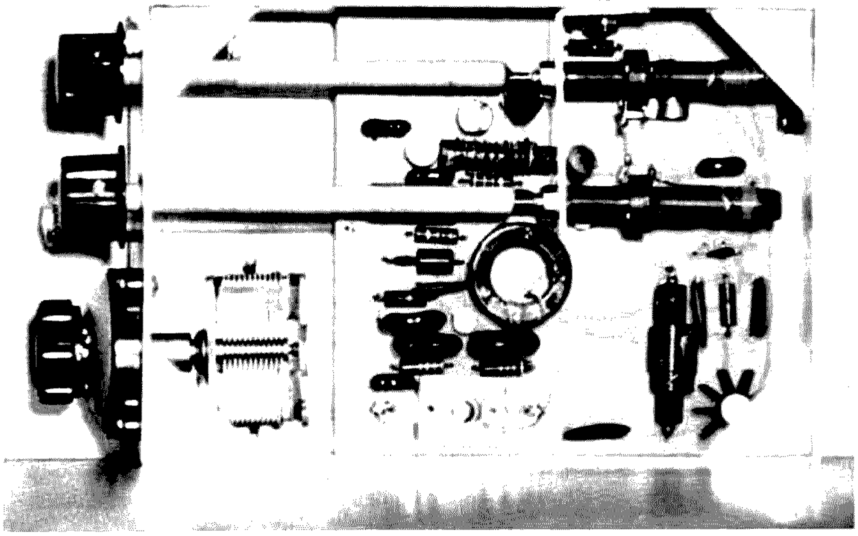
The original bread board view of the Mini-Mite (note the final is missing in this photo) just goes to show that layout is not critical, as this unit worked quite well. Also this prototype used the optional buffer — the two plastic-type transistors just behind the vfo.

Operation

Before you can begin to operate the Mini-Mite, you must provide for the type of keying scheme which will best serve you. For instance, you may wish to key the oscillator for break-in. Fig. 1 suggests some keying schemes. The PC board is set up for keying the driver and final simultaneously. To change from this requires some revision of the printed tracks. Keying the driver and final is convenient and easiest, but has one major disadvantage. Dirty key contacts will increase the chance that some voltage will be dropped across the closed contacts. At the higher current levels encountered at this

point, you can drop, say, a volt or so, and lose effective input power to the final and driver, and degrade the output signal. Keep the key contacts reasonably clean and you should have no particular problems. Tuning up the Mini-Mite is pretty much like tuning any other rig, except that you must also tune a solid state rig for cleanest output signal. You will have to monitor on a receiver as you tune up. You can use a #47 dummy load, but take care not to leave the key down for periods over a minute or so, as the overvoltage to the bulb will burn it out. Tuning to an antenna can be accomplished with a field strength meter, in-line wattmeter, swr bridge on forward power, or a tuning meter as shown in the schematic Fig. 6. Tune for maximum all the way around and you should get the cleanest signal.

Well, for just under twenty dollars, the Mini-Mite is going to make the Novice a fine first rig. Or it will serve the guy who operates portable for fun quite well because it has enough kick to cut through some of the QRM. It also makes a great standby rig for the day when that low band transceiver pops off the air and you would like to tell the guys in the group what happened without a long distance phone call. Usually, when guys are on frequency and looking for you anyway, they will hear a little peanut whistle QRP rig coming in, so you will be able to set 'em straight (if you can still remember the code). And if you're a General or Advanced who has only got a transceiver that won't go on CW, here's your gateway to 20 wpm! ■



Here is the final version of the Mini-Mite component layout. The output transistor has a finned heat sink. The vfo is in the area shown with the toroidal coil although other coils may be used as discussed in the text.

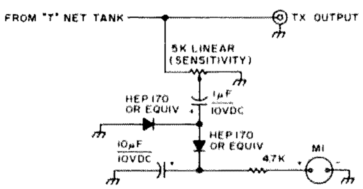


Fig. 6. Tuning meter. MI is a tuning indicator or battery level indicator available from many mail order houses or the XYL's cassette player.

Author's Note:

Add this modification (Fig. 7) to the Mini-Mite schematic. All it amounts to is adding a 100 Ohm resistor and a 1k resistor in the Buffer Amplifier. The 47k bias resistor is dropped so the stage runs class C.

The best way to run the rig as a 1 Watt output QRPer for anyone not interested in going the full 7 Watt route is shown in Fig. 8. Leave out the driver transistor and run a 100 pF between the output winding from the amp stage and the collector connection on the driver, then a 100 Ohm across the PA base to ground.

A Fun Counter Project

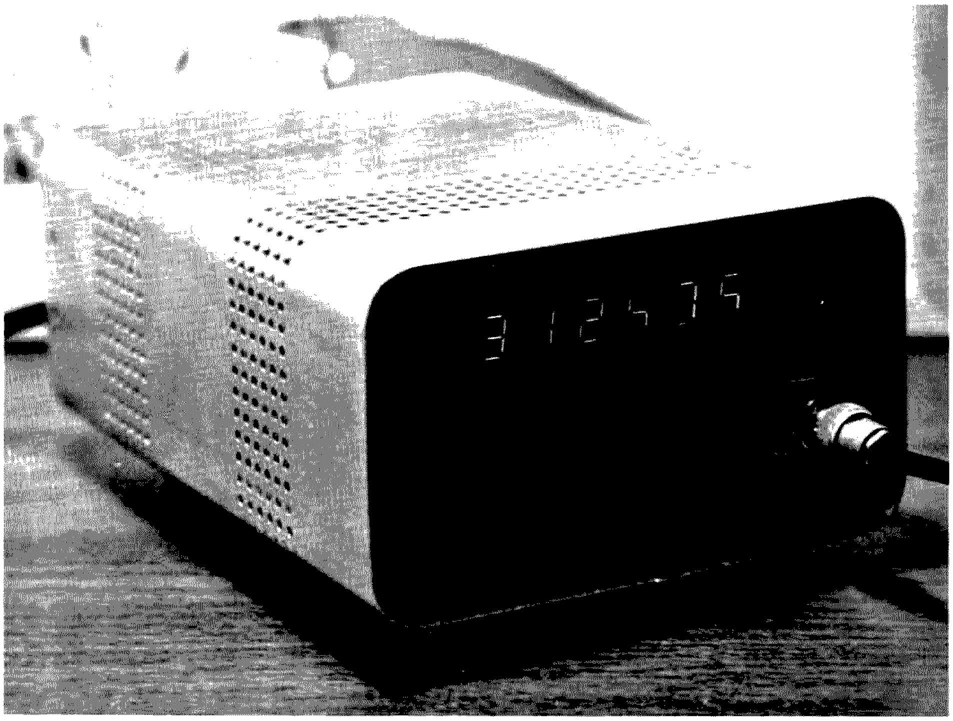
--an invaluable test instrument

for under $50?

Al Plavcan
PO Box 6173
Anaheim CA 92806

My original goal in designing this counter was to produce an inexpensive, no frills, reasonably accurate, minimum parts design. I think I accomplished this for the most part. Read on and see if you agree.

High impedance FET input, .2 to 30 MHz frequency range, sensitivity ≤ 60 mV RMS across most of its range, and compact packaging are some of its features. Also, two modes of timebase operation are possible: xtal controlled with an accuracy of ±20 PPM ±1 count and line frequency (±.05%). The heart of the counter (less readout and power supply) is mounted on 2 PC boards (≅ 3" x 5"). The cost of the boards filled with parts (for line frequency operation) plus the 6 Minitron readouts will run you about $40. An additional $8 pays for the xtal controlled timebase, and of course you'll need a power supply. Any junk box parts substitute will naturally reduce your costs.



Operation

The block diagram of Fig. 1 shows the signal flow and control. Referring to Fig. 2, Q1 to Q4 shape the incoming signal to produce TTL compatible levels. A precise 100 ms gate (at IC19 pin 2) is then "or"ed together with the signal (IC19 pin 3). This gated signal is counted down and displayed on the readouts. The trailing edge of the 100 ms gate triggers the one shot IC24. A pulse is generated that strobes the quad latches IC7 to IC12. The stored data is transferred to

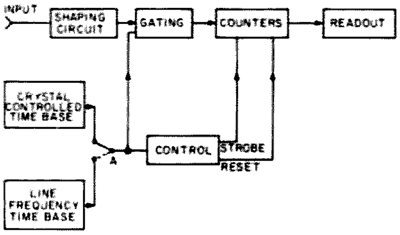


Fig. 1. Block diagram.

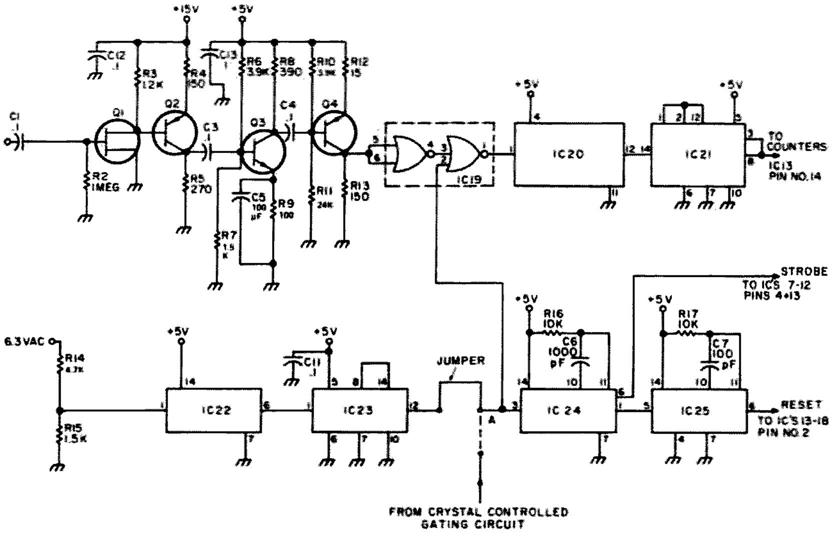

Fig. 2. Input and Control board.

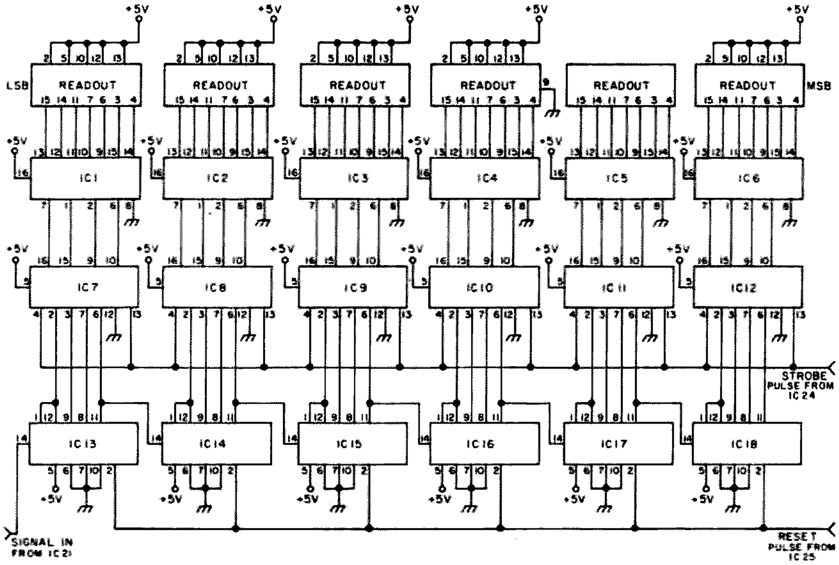

Fig. 3. Display board.

the decoders and readouts. The trailing edge of the one shot triggers another one shot IC25 to produce the reset pulse to counters IC13 to 18. All counters are reset to zero until the next gated input is counted. Thus the sequence is: gate, count, transfer, reset.

Construction

As mentioned earlier, the heart of the counter is mounted on 3" x 5" PC boards (actually 3" x 5-3/16"). You can package these boards any way you like. Just allow sufficient ventilation in any enclosure you use. One of the drawbacks of laying out small boards is that you can't get all the circuit connections on them that you'd like. So we're going to have to add some jumpers. Refer to Fig. 2 and Fig. 5. After all the components are mounted, jumper IC19 pin 2 to IC24 pin 3. Also jumper point "A" to the pad right above it (for line base operation). That's all the jumping we need for the Input and Control board.

The Readout board will require the following jumpers (refer to Fig. 3 and Fig. 6):

1. IC7 to 12 – jumper all pins 4 and 13 (strobe).
2. IC13 to 18 – jumper all pins 2 (reset).
3. IC13 to 18 – jumper pins 1 and 12 on each IC only.
4. IC13 pin 11 to IC14 pin 14.
5. IC14 pin 11 to IC15 pin 14.
6. IC15 pin 11 to IC16 pin 14.
7. IC16 pin 11 to IC17 pin 14.
8. IC17 pin 11 to IC18 pin 14.

Also, power to all ICs and all power grounds will have to be added. Refer to Fig. 3. Jumper grounds to the ground plane and between boards. I suggest you use Molex terminals to mount all ICs. The added cost is worth it.

The Input and Control board artwork (Fig. 5) is laid out for 60 Hz operation. If you're satisfied with an accuracy of approximately 500 PPM on your counter,

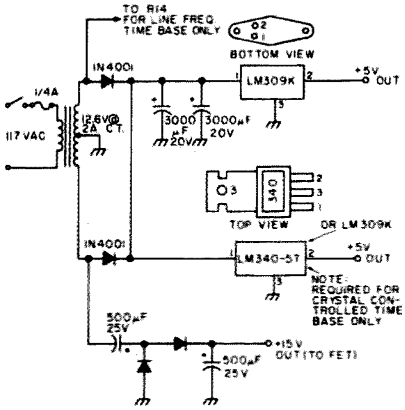

Fig. 4. Power supply.

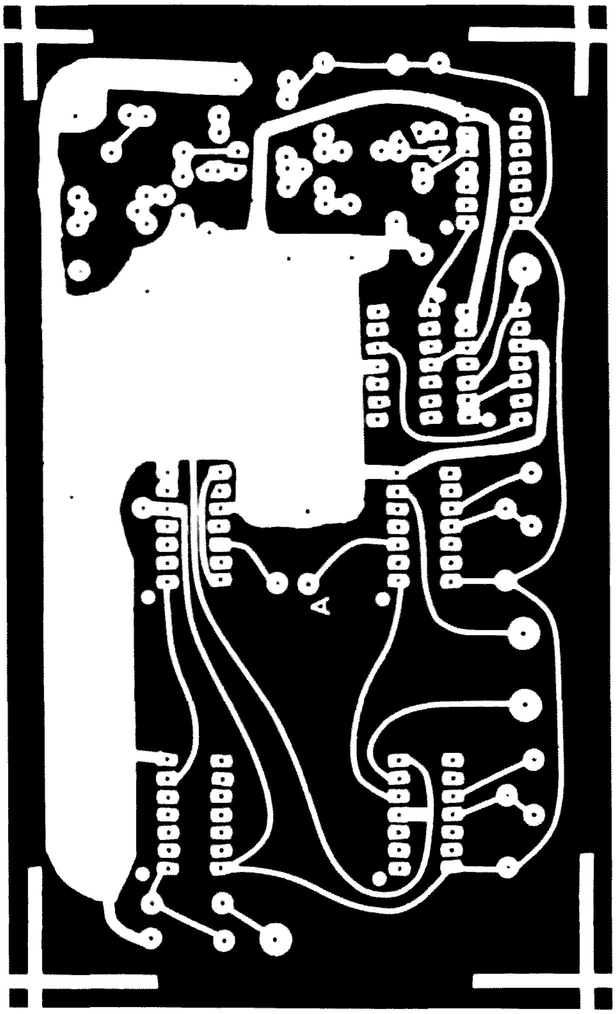

Fig. 5(a). Input and Control PC board, full size.

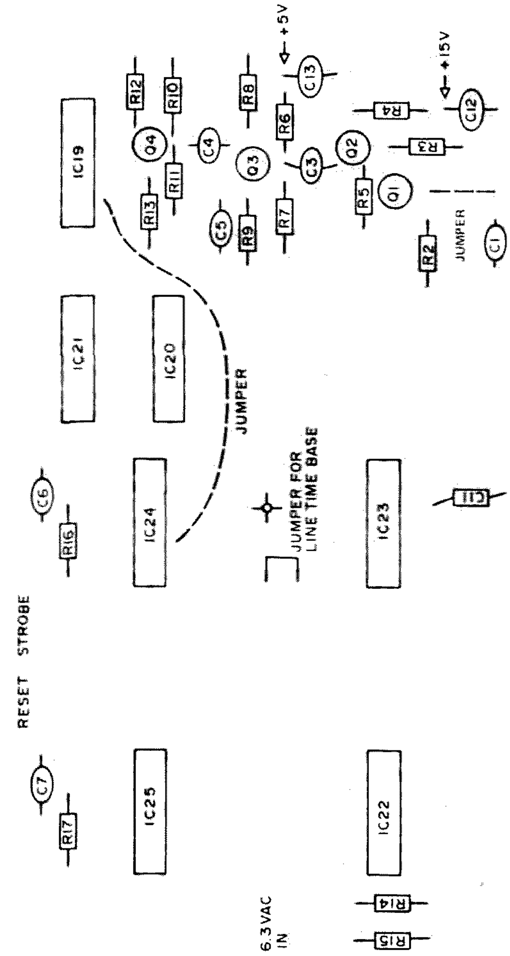

Fig. 5(b). Component layout, Input and Control board.

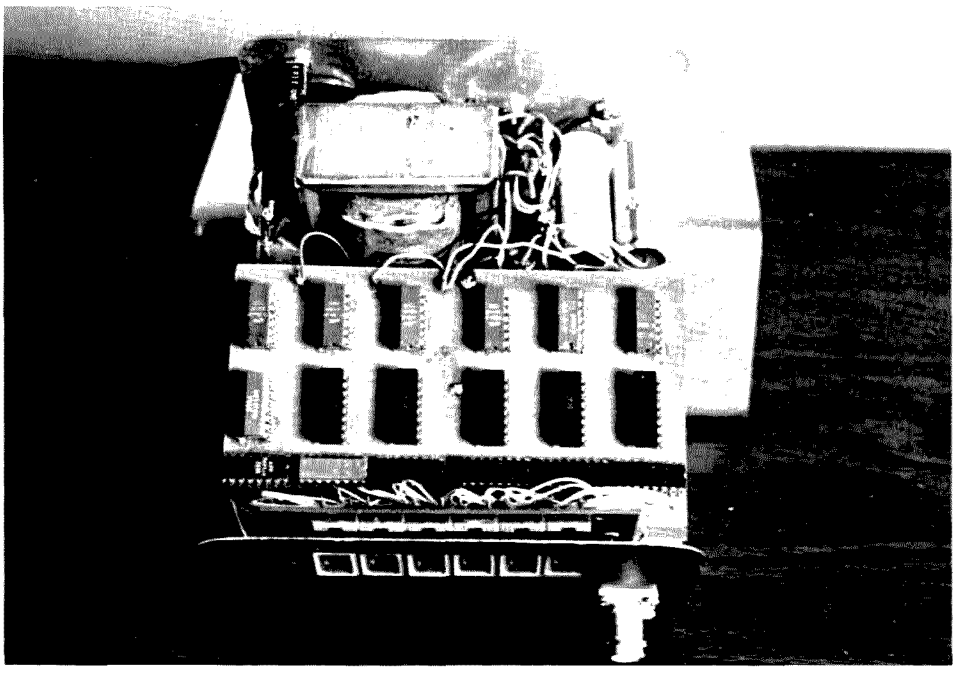
use it as is. You won't need the LM340-5T in the power supply, so that's an additional saving.

The crystal controlled timebase should be added to get the most accuracy from your counter. Fig. 7 is a suggested circuit. There is no artwork included for this additional circuitry. Layout is not critical and could be hand-wired in no time. If used, you won't need IC22 and IC23. To connect, remove the jumper at point "A" and connect the output on the last counter to point "A".

That's about it. If you got all the jumpers in right and your power is connected right (double check), you should be finished. The dot near each IC on the artwork is pin



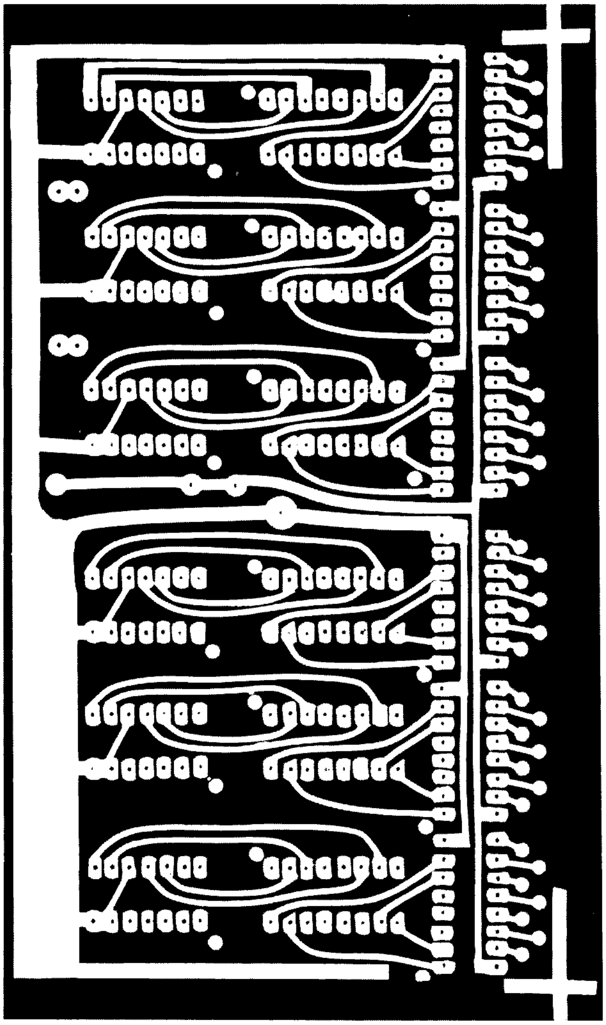


Fig. 6(a). Display PC board, full size.

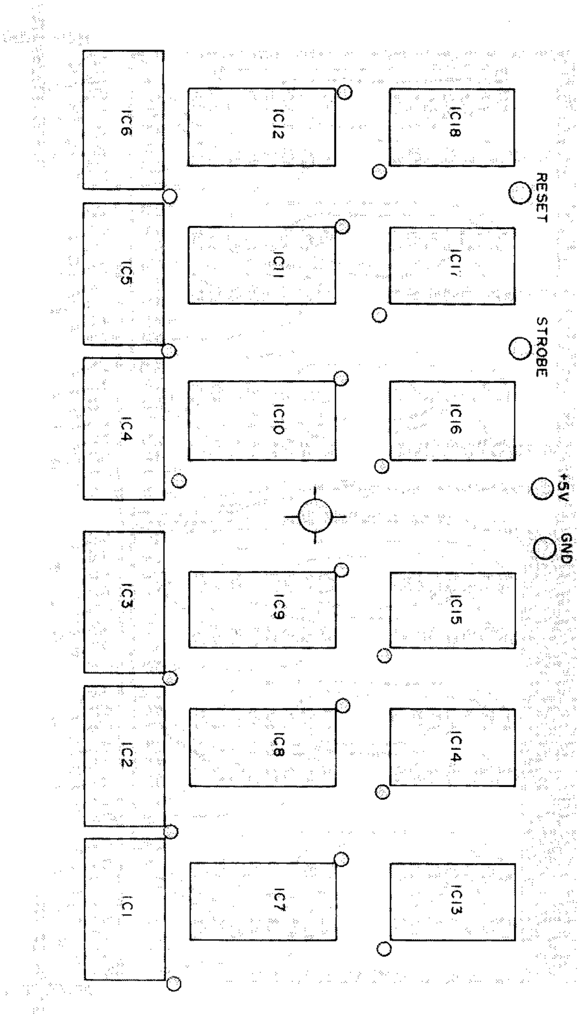

Fig. 6(b). Component layout, Display board.

1. Make sure all ICs are installed correctly. That's another reason for using the Molex terminals. It's a lot easier to reverse an incorrectly mounted IC with them.

There is no calibration procedure. If it's wired right, it'll work. One word of caution. If the counter fails to count all the way to 30 MHz, IC21 could be the cause. It has to divide by 5 up to 15 MHz. Substitute it with other 7490s until you get one that goes to 30 MHz on the input.

Finally, your counter is compatible with any of the prescalers available on the market, extending its range to 300 MHz. ■

Note: For a more versatile counter, and to prevent overloading the front end, the input circuitry shown in Fig. 8 should be added.

NEW PRODUCTS

ICOM's IC-202

What has two meters, three Watts, and a swinging VXO wrapped up in a $280 package? The IC-202, of course!

A few months ago, Jay W6BWB, took his Japanese-born wife Kiyo to visit relatives in Japan. A trip to Akihabara, Tokyo's Electronics District, was also on the agenda. It was a fortunate bit of timing that ICOM had just introduced six meter and two meter walkie-talkies in Japan since Jay was "hot to trot" to get on two meter sideband after monitoring the activity for some months. It was also fortunate because the price was very reasonable when compared to other units available.

So he bought the rigs (for six and two). Listening on six or two in Tokyo was an eye-opener. I suppose it was because of their code-free license (held by many very technically competent engineers, by the way), but the bands were filled with activity day and night. Even from 60 miles outside of Tokyo, Jay found high activity.

Back in the states, the rig proved quite adequate for local QSOs out to 60 miles or so. The surprise came when he was able to work Los Angeles and San Diego some 320 and 420 miles down the mountainous coast of California! Jay's QTH is one of the better ones in Santa Cruz, but even with his KLM 16 element beam and 70 foot tower his total height above sea level is less than 125 feet. No matter how you slice it, 420 miles on 3.2 W PEP is nothing to sneeze at!

I've been able to check out two IC-202's at SBE's engineering facility. Both showed good results. Both had less than 0.125 uV sensitivity for 10 dB S+N/N ratio. Both gave better than 70 dB intermodulation rejection (+10 and +20 kHz signals required to equal the level of the desired signal). The AGC is reasonable . . . 15 dB audio change for over 70 dB rf change (0.3 uV-1,000 uV). Audio output is adequate for a portable package but may be marginal in noisy vehicles in mobile service . . . about 1 W.

The transmitter shows good design with spurious and harmonic content below the 70 dB range of the Spectrum Analyzer. Distortion products at the 3.2 W level allowed by the ALC are better than 30 dB below each tone (-36 dB by ARRL standards). Some have been able to increase the output to over 4 W PEP by backing off the ALC, but the 1.5 dB gained by doing this is probably not worth the 5-6 dB of additional "garbage" it causes.

The unit's size makes it a natural for trips, mountain-topping, battery operation, "natural power," and emergency use. It is roughly the size of the popular TR-22 FM transceiver (2¼ x 6½ x 7½). It features built-in batteries (nine "C" cells), internal whip antenna, external power jack, external antenna jack (SO-239), and external speaker jack.

The VXO covers two ranges as it comes from the factory, 144.00-144.20 and 144.20-144.40. Two additional ranges are available or an external VFO can be used. The VXO is calibrated in 5 & 10 kHz steps and can be set within about 1 kHz of a desired frequency. While this is not as accurate as rigs like the Echo II (which can be set within 100 Hz), it is good enough so that you can tell that a station is there.

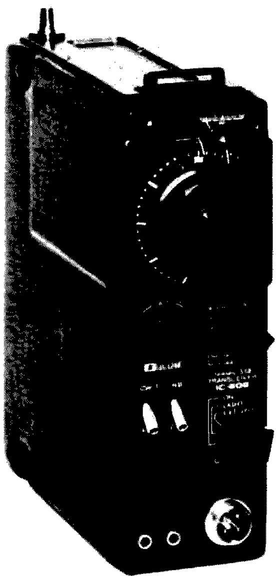
The rig sports Receiver Incremental Tuning (RIT) so that the receiver can be tuned independently from the transmitter. The RIT has a center-off detent.

CW is accomplished by throwing a front panel switch each time CW is desired. This sets up a carrier shift of about 1 kHz for automatic offset. Some may find that the switch is inconvenient as it must be turned off again in order to receive. However, this is a minor inconvenience. CW output is about 4 W.

The "S" meter is of the "hang" variety making signal levels easy to read. Since it works off the AGC line it does not read below 0.5 uV, however, even though this is well into the "Q-5" area. The "S" meter doubles as an rf output indicator.

There is no squelch on the IC-202. While this is not considered a problem by many sideband operators, I like to have it on my rigs. I find it convenient.

Of the seven or eight IC-202 owners in the San Francisco Bay area, I don't know of any who have been disappointed with their units. Some have had some drift problems because of temperature variations in mobile service, but part of this seems to be traceable to using cheaper grades of American crystals not specifically cut for VXO service. ICOM has not published full specifications for the crystals and so far only includes 144.0-144.4 crystals. Since operations in many parts of the country center around 145.010 in keeping with the .010, .110 tradition on other VHF bands (6m, 2m, 220, 432, 1296), ICOM might do well to include the 145.0-145.2 MHz range at least as an option. This might eliminate the spec problem.



Speaking of frequencies, due to the very rapid growth of SSB in the San Francisco Bay area we have frequent QRM problems when QSOs get going in several communities independently. Since cross-town signals are quite loud, signals from other areas often aren't noticed. However, the poor guy located in between two such QSOs ends up with a real problem!

Perhaps a lesson from the 11 meter bunch would be in order. We've already made a gentlemen's agreement to use 145.005 for "DX" with 145.010 for monitoring and calling. Then "private" QSOs move up 20 or 30 kHz to get out of the way. CBers go one step further in that each community has its "channel" so that when they QSY off the calling channel they don't end up on distant QSOs. While something this formal might not be desired, it has the advantage that one can find someone in a specific area by calling on that frequency. I figure if "Red Rover" can handle it, hams ought to be able to do it!

One last comment. Bob WA6MUG took his 202 up to Lick Observatory on Mt. Hamilton (3500 feet). He worked many Bay area stations plus several hams down at Webster Radio in Fresno . . . some 120 miles. Signals were very good all the way around. The clincher is that Bob was using *battery power* and the *internal whip antenna!* The IC-202 promises to be a fun radio.

James Eagleson WB6JNN
Santa Cruz CA

Build a FAX from Scratch

-- repeater control, with ID

Most anyone who owns one will agree that finding a surplus facsimile machine was something of a mixed blessing. The unit is probably large and unwieldy; replacement parts are a problem; and some modification was likely to be needed before the recorder could be used. The alternative, customizing one's own FAX machine, isn't really too difficult. The recorder presented here requires no great amount of mechanical ability to construct. It is an electrolytic type. Chemically treated paper is drawn between a rotating helix (nichrome wire) and a steel blade. A potential between blade and helix causes a marking ion to be deposited on the paper. The unit will record FSK transmissions of weather maps, as well as some wire service photo transmissions, though the latter will suffer mirror image in recording – pictures come out reversed with respect to left and right.

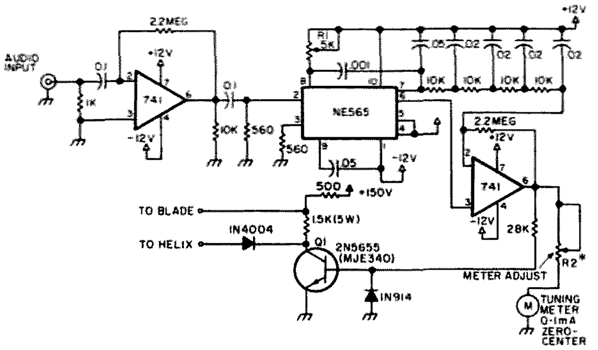


*Fig. 1. Demodulator. *Adjustable dropping resistor for zero-center milliammeter.*

73 Magazine has published a series of interesting articles on facsimile during the last several years: "An IC Facsimile Receiving Converter," Brockman, January, 1974; Ralph Taggart's series, "A Satellite FAX System You Can Build," August, September, and October, 1975; "A Fast Scan Facsimile System with SSTV Compatibility," Winkler, March, 1973; and "Facsimile for the Radio Amateur," Dean, August and September, 1971. I suggest that this material be explored before getting into the project. In particular, the article by Bob Dean (of Alden Electronic & Impulse Recording Equipment Co.) should be reviewed. It is an informative and comprehensive report on amateur facsimile.

Clyde B. Lee, Sr. W4NK
117 Woodmore Ave.
Louisville KY 40214

There is one definite prerequisite before getting underway. A little Western Union Telefax transceiver will be needed for a source of gears and bearings (and some electronic components). These "deskfax" units are still plentiful on the surplus market. If there is any difficulty in finding one locally, I can supply a source ($5.00 for the unit plus shipping). Please include a self-addressed

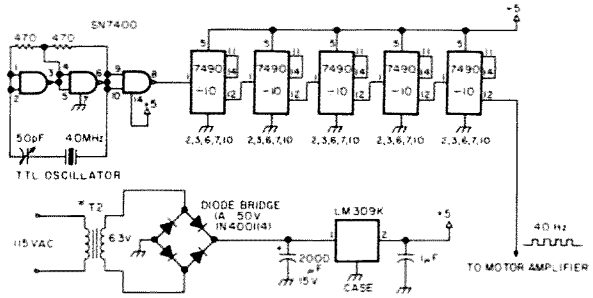

*Fig. 2. Precision ac source. *Filament transformer from deskfax.*

stamped envelope with your request.

Electronics

The demodulator, Fig. 1, is merely a RTTY terminal unit. A suitable lead resistor and diode have been added to optimize it for facsimile. This circuit, employing an NE565 phase locked loop, was presented by Nat Stinnette W4AYV in the February, 1975, issue of *Ham Radio Magazine.*[1] The demodulator works on the FM principle. The voltage-controlled oscillator of the NE565 locks onto the incoming signal and tracks it between the frequencies of the black (1500 Hz) and white (2300 Hz) tones, resulting in a corresponding dc shift at the output. A voltage comparator connected to the output of the PLL produces plus and minus voltages to activate printing transistor Q1. A zero-center milliammeter functions as a tuning indicator.

The precision ac source Fig. 2, supplies 40 Hz to a 50 Watt class B motor amplifier, using a pair of 6550 tubes connected as zero-biased triodes. Inasmuch as the deskfax operated at 180 rpm (60 Hz supply), 40 Hz is required to lower the speed of the synchronous drive motor to produce 120 rpm. The 120 rpm helix rate is required to copy weather map and some wirephoto transmissions. The little TTL crystal oscillator circuit is a "surefire" one from *QST*, February, 1974, p. 34. When others are cranky, this one will work!

I used the following procedure to select T_X, the motor amplifier output transformer (see Fig. 3). The method requires a known composition resistor, VTVM, and filament transformer (part of a more extensive routine by WØMKF in *Ham Notebook* for determining values of unknown inductances). The setup will only give ball park values of impedance, but that's close enough:

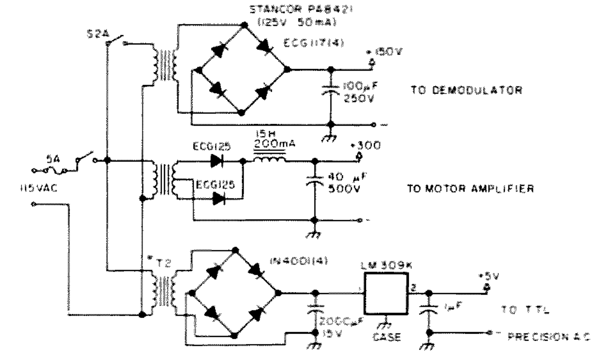

*Fig. 3. Power supplies. *T2 — 6.3 V from deskfax. S2 — DPST switch.*

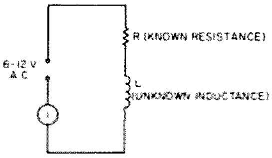
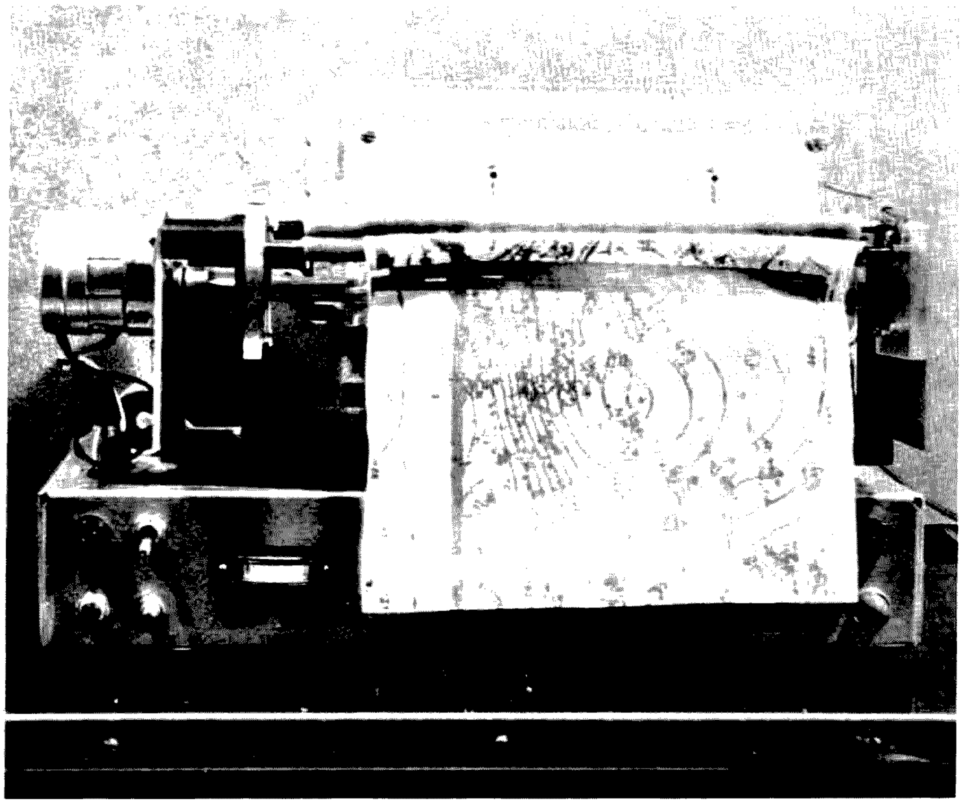
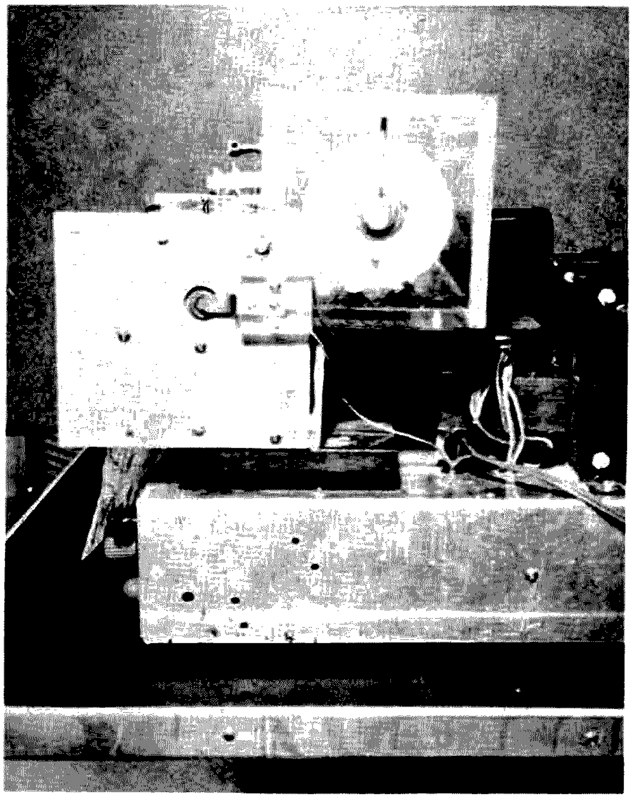
1. Measure ac voltage across known series resistor.
2. Compute I from E/R_L.
3. Measure ac voltage across inductance.
4. Compute Z from E/I.



Applying the method, in turn, to deskfax motor windings, primary and secondary of a surplus (unmarked) power transformer on hand, the following values were obtained:

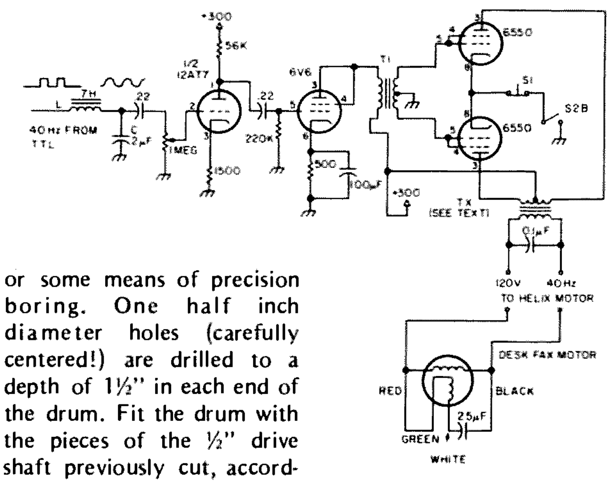
	Z (Ohms)
Deskfax:	750
Primary:	1400
Secondary:	20k





Helix contactor.

Fig. 4. Motor amplifier. T_X – see text. T1 – Stancor A4713. C – Stancor C1707. S1 – N.C. SPST push-button switch. All resistors ½ Watt 10%.



That's the best combination my junk box could produce – anyway, it works!

In the motor amplifier, Fig. 4, L and C (7 Henry choke and 2 mF capacitor) filter the square wave 40 Hz tone from the TTL source to an acceptable sine wave for the amplifier. In selecting the output transformer, T_X, select a husky one, 115 V primary, with a secondary around 350-0-350 V at 175 to 200 mA.

Mechanics

As a first step, dismantle the deskfax. Disengage the traversing mechanism. Rotate the drum and slide it slowly to the left. As you look through the hole in the drum you'll see a brass screw in the drive shaft. Remove the screw. Loosen the collars and fiber gear. Now the half inch drive shaft can be removed from the left. Remove the cradle and strip it. Remove the following electronic components: the push-button switch, the 6.3 V filament transformer, and the 2.5 mF motor capacitor.

Cut the cradle in two, making the cut 4-3/4" from the left end (the bronze sleeve bearings should be covered to protect them from filings). Next, cut the 1/2" steel drive shaft as follows: from the left end of the shaft, 1 piece 4-7/8"; from the right end of the shaft, measuring from the shoulder, 1 piece 2" long. (This allows ½" clearance between the end of the helix drum and the right bearing.) See Fig. 5. Center and drill and tap the bearing end of the 2" piece for a ¼" 4/40 screw (this will be a wiping contact).

Helix

I've used Wink W6WMI's system in constructing the helix. (See Fig. 5.) The helix drum is a plexiglas rod 1½" diameter, 10" long. This *is* a step that will require a lathe or some means of precision boring. One half inch diameter holes (carefully centered!) are drilled to a depth of 1½" in each end of the drum. Fit the drum with the pieces of the ½" drive shaft previously cut, according to Fig. 5. Drill and tap for a 4/40 screw ¼" in from the right end of the drum. This screw must go through the wall of the drum and make good electrical contact with the drive shaft. Drill and tap for 6/32, ¼" screws to anchor the #22 nichrome helix wire. The screws are located ¼" in from each end of the drum and positioned to form a 370° lead (one spiral turn occupying 9" with about 5° overlap at each end).

Looking at the right end of the drum, rotation will be counterclockwise. The nichrome wire is to be wound clockwise (sweep will be from right to left as contact is made with the blade). Snug the wire up as tightly as possible on the drum, then pass the free right end over to be fastened by the contacting screw.

Cradle

Using a 3/16" bit, drill any additional holes needed in the base of each of the two pieces of cradle previously cut. Set the pieces on a plexiglas sheet 3/8" by 4½" by 14¼". Temporarily install the helix and align it so that it turns smoothly. Mark the mounting holes, then drill and tap for #8 screws. A 13" by 17" by 3" chassis is used for assembling the recorder. Place the plexiglas base (above) on the chassis. At this time install whatever you intend to use for shock mounts. There should be at least 4. (Excellent shock mounts are available from the deskfax, but there are only 3.)

Paper Humidor

An aluminum plate 1/8" by 3½" by 10" is to be installed on the flange of the right cradle member (this flange formerly supported the optical system). Position the plate so that it overlaps the forward edge of the flange ½" and is aligned with the right end of the cradle. Before mounting the plate, using a 3/16" bit, drill holes in each corner of the plate for mounting the paper humidor.

The Alfax paper must be kept moist for the electrolytic process to work; so while the plexiglas enclosure does add to the expense of the project, it is an essential part of the recorder. IPS Weldon #3 solvent (or other suitable brand) is used in assembly. You'll need an applicator. I paid the additional price and had the distributor cut the pieces to size. See Fig. 6. The box goes together easily – just tack the members with a few pieces of Scotch tape, apply the sol-

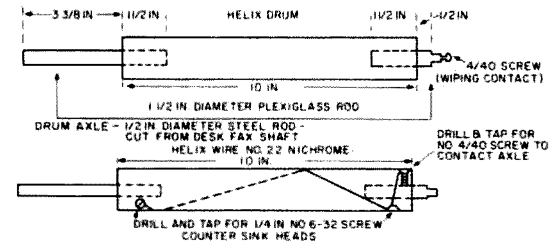


Fig. 5. Helix.

vent, and in a matter of seconds the pieces are *really* welded. Note that paper will be fed through a 1/8" slit, formed by pieces A and B of the front of the humidor.* Next cut out two supports for the Alfax paper. Use 3/8" plexiglas and cut to the dimensions of Fig. 6. Center these at the ends of the interior of the humidor and cement with solvent. Align the top, then drill and tap for a ½ inch 6/32 screw at each end. Place a roll of Alfax paper in the humidor and replace the top. Drill and tap for a 6/32 screw 2" long that will extend down through the cover and contact the hub of the paper roll. These should be about 9/16" in from the end of the cover and in line with the center of the hub. Do this for both ends. The 2" 6/32 screws installed will function as "brakes" to control the flow of paper.

Blade Assembly

Cut a piece of 3/8" plexiglas to 1¼ by 9½". Install steel pins at each end, as in Fig. 7. (Material for the pins can be taken from the deskfax push-button switch assembly.) Cut a piece of ½" aluminum angle and install with 4/40 screws as shown. The two screws at each end at the top will anchor two phosphor-bronze motor brush springs. The three screws along the forward edge will secure the blade,[2] wedging it between the plexiglas and the aluminum angle. (The National Weather Service and some TV stations use Alden facsimile recorders that use a blade in the form of a steel loop. These are discarded after a little wear and are a good source of material for the blade required here. 9½" sections can be cut from the loop.)

Paper Feed Assembly

See Figs. 8 and 9. The paper feed mechanism is driven by a 5 Watt, 115 V, ½ rpm, 60 Hz synchronous motor. This is a Hurst, Model CA, available directly from the Hurst Mfg. Co., Motor Division, Princeton, Indiana, currently at $18.06. This speed (½ rpm) with ½" rollers, produces a 9" by 11" recording. Not exactly symmetrical, if one is a purist. The rollers are made by slipping 10-3/4" lengths of rubber tubing (½" O.D., ¼" I.D.) over ¼" steel rod (the material should be turned and ground shaft or drill rod). The driven roller is 13-1/8" long; the idler is 11-7/8". Ball bearings (NICE type 1602 DC) are used for the driven roller. The bearings are 11/16" O.D., ¼" I.D. The tension springs, E and F, are 1-3/4" long, cut from the traversing mechanism (spring) of the deskfax. Reference Fig. 9: the 3/16" diameter holes at O and P are to be at a depth of 3/16" on the inner surfaces of supports A and D. These will retain a 3/16" rod (preferably brass) to smooth and align the paper as it emerges from the slit in the humidor. The bottom of the rod should align with the top of the helix and be positioned about 5/8" forward from the center line of the helix. (This detail is not shown in the exploded view of Fig. 8.) Two aluminum "end plates" of 1/8" material, each 4½" by 5¼", support the paper feed assembly and the contactor for the helix wire. See Fig. 10. A coupling 1" long will be required to couple the 3/16" motor shaft to the ¼" roller rod (you'll probably have to make this). Place the plexiglas supports, A and D, on their respective end plates, and align the top and forward edges. Mark the mounting holes and the center line of the driven roller shaft. Drill a 5/16" hole for the motor shaft. This is to be expanded to 1/2" after the motor mounting holes have been marked and drilled.

A 3/4" diameter hole is to be drilled in the right end plate, 1-3/4" from the top edge, 2-7/8" from the forward edge. This is for the rotating contact (a 4/40 screw) in the right end of the helix drive shaft. The contactor is merely a piece of "springy" brass mounted on a small piece of 3/8" plexiglas.

Getting It All Together

Install the fiber gear and then the 7/16" collar at the left end of the helix drive shaft. Install the helix drive motor in the left cradle member. Place the helix in the sleeve bearings and mount the assembly to the plexiglas base. Position the aluminum end plates with the bottom edges aligned with the bottom of the cradle, and with the rear edges aligned with the rear edge of motor support. Attach these to the ends of the cradle with #8 screws (2 in the lower edge and 1 on the uprights that house the sleeve bearings). Press the ball bearings into the 11/16" holes in the plexiglas supports (A and D). Slip the paper smoothing rod into each support, seating it at O and P (Fig. 9). Install the driven roller. Attach this assembly to the aluminum end plates. The left support, A, will require 3 spacers 1½" long. These can be made up of 3 sets of 3/8" O.D. spacers for #8 screws, ½" long (H. H. Smith #2119) and 1" long (H. H. Smith #2117). Slip the coupling onto the left end of the roller shaft; mount the motor. Mount the springs and adjustable bearings (Fig. 8) for the idler roller. Install the aluminum base plate for the paper humidor. Place the humidor on the plate, centered with the helix, and with its front 1-1/8" from the center line of the helix. Mark and attach the humidor to the plate (use ¼" screws). Slip the left pin of the blade

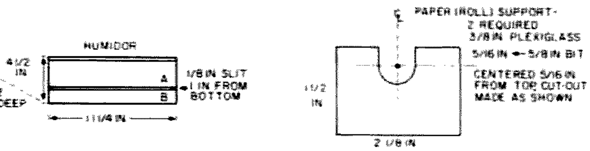

Fig. 6. Humidor and roll supports. Humidor (3/8" plexiglas): 2 pcs. 3-3/4" x 3-3/4" (ends); 1 pc. 4-1/8" x 11-1/4" (back); 1 pc. 3-3/4" x 11-1/4" (bottom); 1 pc. 4-1/2" x 11-1/4" (top); 1 pc. 2-5/8" x 11-1/4" (front); 1 pc. 1-3/8" x 11-1/4" (front). Assemble with IPS Weldon #3 solvent.

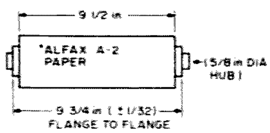

*Fig. 6(a). *Alfax paper collapsible core.*

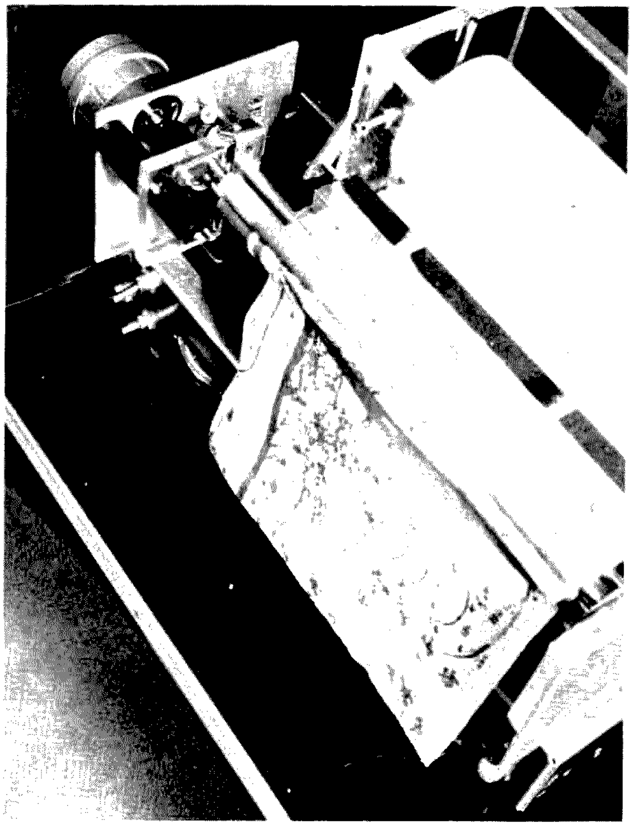
***Plexiglas, solvent, and rubber tubing were obtained from General Rubber & Supply Co., 3118 Preston Highway, Louisville KY.**

assembly into its mounting bracket (a piece of 1/8" brass, ½" by 3"). Rest the blade on the helix, center it, and, with the blade assembly leveled, mark the right end plate for a 1/8" bearing hole. Similarly mark and mount the left bracket. (Small thin pieces of brass, attached with 4/40 screws to the outer surfaces of the bearing members, will prevent lateral movement of the blade assembly.) Two #8 screws, 1¼" long, support the phosphor-bronze motor springs (Fig. 7). Use a #55 (or similar) bit and drill a hole adjacent to the head of each screw. Drill and tap the front wall of the humidor for these #8 screws, 1" from the top and 1¼" inch from each end. Two ¼" hex spacers, 1" long, threaded for a 6/32 screw (H. H. Smith #2324) are drilled and tapped for a 4/40 screw at ¼" from an end. Run a locking nut down on two 4/40 screws, 3/4" long, and then install in the hex spacers. Solder compression-type springs (I cut them from a transistor heat sink clip) to the tips of each 4/40 screw. Thread small gauge copper wire through the holes in the #8 screws after installing them in the front wall of the humidor. Secure the ends of the phosphor-bronze springs (the other end of the springs should be fastened to the aluminum angle of the blade assembly). Solder a lead to the right spring. Attach the helix contact to the right end plate, centering it on the 4/40 screw head from the drive shaft. Put a few drops of #10 oil on the sleeve bearings and worm gear. Turn the helix by hand to see that everything is still aligned. Set the collar and fiber gear in place. There should be just a tiny amount of backlash with the fiber gear and worm – and a similar "tiny" amount of end play between the collar and left bearing. Apply power to the helix drive motor to make any final adjustments of the 4 mounting screws necessary for smooth operation. Pour a small quantity of water into the humidor, and, assuming all of the electronics are functioning perfectly(!), place a roll of paper in the recorder and look for NSS!

Operation

Fleet facsimile broadcasts are made from NSS, Washington, D.C., on the following frequencies (kHz): 3357, 4975, 8080, 10865, 16410, and 20015. Incidentally, publication H.O. 118, available from the U.S. Naval Oceanographic Office, Washington, D.C., contains a wealth of data on worldwide FAX weather broadcasts (as well as RTTY). There is also information on interpreting weather codes.

This is the procedure I used with a Drake SSB receiver, an R4B, to adjust the PLL demodulator. Tune in the NSS signal (upper sideband). Most transmissions are of about 10 minutes duration, with 800 Hz shift between 1500 Hz (black) and 2300 Hz (white). Set R1 of the demodulator fully clockwise (maximum resistance). Tuning to the 2300 Hz tone



Paper feed detail.

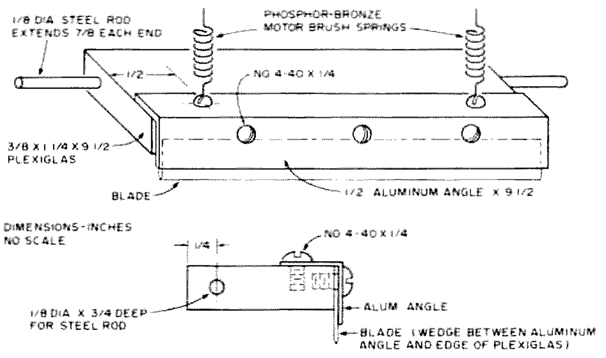


Fig. 7. Blade assembly.

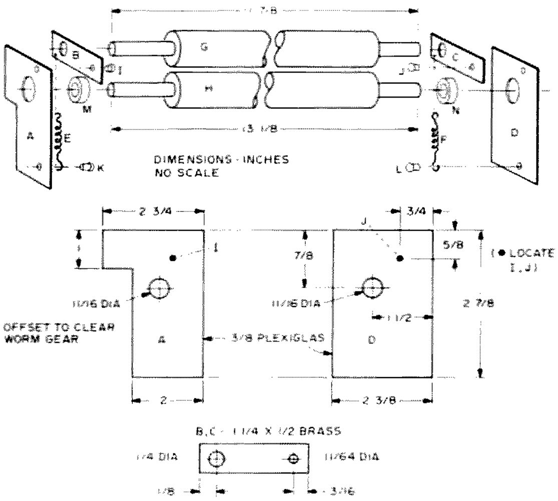

Fig. 8. Paper feed assembly (not to scale). A, D: left and right supports, 3/8" plexiglas. B, C: top roller bearing, adjustable brass, 1/8" x 1/2" x 1-1/4". E, F: tension springs. G, H: rollers. I, J: #8 screws, 1/4". K, L: 4/40 1/2". M, N: ball bearings.

should cause the zero-center milliammeter (tuning indicator) to deflect toward maximum negative. The 2300 Hz tone is transmitted between maps, so this is a good time to check the tuning indicator and set it for maximum deflection. Remain tuned to the 2300 Hz tone until a start tone is heard, indicating the beginning of the next map transmission. This will be a lower tone (I believe it is 675 Hz). This will be transmitted for 10 seconds, and will be followed by about 30 seconds of phasing pulses. During this time, with the recorder running, you should see the recording coming in as a field of black with a white line (about ½" wide) in the field. Momentarily activate the phasing switch (push-button) and note the shift of the white line to the right. Continue to pulse the phasing switch until you have the white line at the left edge of the paper. You now have your drum phased with that of NSS for proper reception of the map. The copy will probably look thin and skimpy with this setting of R1. Back off on R1 slightly and retune the signal. Note that you are able to control the width of lines in the recording (to some degree) by the setting of R1.

The recorder will copy wirephoto transmissions made at 120 rpm. Wirephoto transmissions will be on lower sideband (and inasmuch as press frequencies are private, it would be inappropriate to publish them here). I can say that occasionally I've tuned above 15690 kHz and come upon a signal that sounds like a flock of nervous wild turkeys, and with a little jockeying around the lower sideband, was able to get a picture.

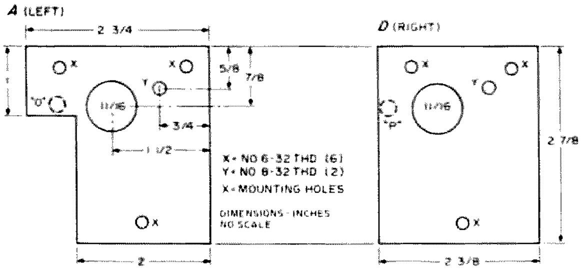

Fig. 9. Paper feed supports (3/8" plexiglas). Drill and tap each piece for 8/32 ¼" screw, 3/4" from forward edge, 5/8" from top. Drill 11/16" hole for ball bearing, on each piece 1½" from forward edge, 7/8" from top. 0 and P: 3/16" diameter holes to a depth of 3/16" on inner surface of each piece, 7/8" from top, 2¼" from forward edge, to retain 3/16" smoothing and aligning rod (brass, 3/16" x 12¼").

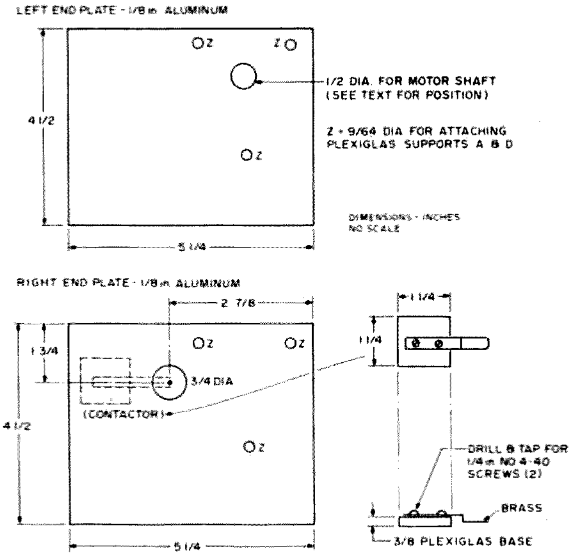

Fig. 10. End plates for paper feed assembly.

Options

If a smaller format is preferred, Alfax paper is available in various widths: 8½, 6-1/8, 5½ inches (¼ inch is to be added to accommodate flange thickness). A 19 inch format with paper feed of 96 lines per inch is more or less standard in facsimile transmissions. Lines per inch are increased with a smaller format, according to the relation:

$$\text{LPI} = \frac{\text{Helix rate (rpm)}}{\text{Paper feed (in./min.)}}$$

One would merely have to rewind the helix, select a paper feed motor with slower rpm (or decrease the diameter of the rollers), and adjust the paper roll supports accordingly.

Acknowledgement

Credit should be given to Lindsay Winkler W6WMI for much of the mechanical detail here. As an inspection of his "Fast Scan FAX System" (March, 1973, *73 Magazine*) will show, I've drawn freely on his ingenious design of helix and paper feed mechanisms. I am indebted to "Wink" and also to Nat Stinnette W4AYV for simplifying the project. ■

FCC SLOWNESS

First of all I would like to say that I, for one, like the new format of your magazine and your section on computers. I would like to see more future articles pertaining to the use of minicomputers in ham radio.

Secondly, I would like to comment on the long waits that the FCC puts prospective hams through for the return of tests, licenses, etc.

Recently I passed the Novice class examination and am now waiting patiently for my license to return. After waiting six weeks for my test to arrive (which was supposed to have taken three), I am now steeled to wait another eight weeks or longer for my license return.

I know that the surge in CB licenses has put utter chaos into the offices of the FCC. I would like to suggest that, as many others will agree, something should be done to keep the CB licenses separate from the ham licenses and reduce waiting periods down to tolerable limits.

With CB licenses, no one waits for that coveted piece of paper to arrive before going on the air. As a matter of fact, 99 out of 100 times they will start "ratchetjawing" as soon as they have their set operable.

Not so with ham radio. The prospective ham just sits there listening to the QSOs with a longing in his heart to be able to join in and aggravation in his brain knowing that all that is keeping him from it is the slowness of the FCC.

I would also like to comment on ham radio public relations. I work for the local newspaper in Scottsboro, Al., and we are more than glad to offer PR to hams. All that it takes with most newspapers is to let the editor know of the usefulness of ham radio and to be willing to be interviewed about the subject.

I have enclosed a clipping out of our paper that I wrote as PR for our second Novice and General license study class that is conducted at the local trade school by Richard Matthews WA4NWW. The response was good and helped to secure more students for our second class.

Please start including more building projects for the Novice, as I am sure that there are lots of Novices out there who would appreciate some simple projects to add to their station.

I would also like to take this time to express my appreciation to Richard Matthews WA4NWW, for the patience and understanding he showed in helping me to pass my Novice test.

Now, if my license would only hurry.

Larry Jackson
Section AL

HERE'S HOW

Ham Radio Classes Are Now Offered

WE ALWAYS GET OUR MAN

A Montgomery Amateur Radio Club member may have averted a tragedy on Monday, March 22, when he observed what appeared to be an assault and possible kidnapping.

The amateur radio operator, Ralph K3CMY, had just emerged from a store on Route 124 near Gaithersburg (MD) when he saw a man cursing and striking a woman. The man then forced the woman into an automobile as she resisted and screamed for someone to call the police. K3CMY reached for the microphone on his mobile FM radio and dialed the Montgomery County Police through the telephone autopatch of the club's Rockville FM repeater station. The car containing the man and woman pulled out onto Route 124 and headed north.

The Montgomery County Police advised Ralph that a patrol car was not immediately available. Ralph volunteered to try to keep the car in sight and the autopatch open. The dispatcher agreed.

On Muncaster Mill Road, near Redland, Ralph spotted a Park Police patrol car and advised the Montgomery County Police dispatcher of this possible source of help. The Park Police stopped the car carrying the man and woman and the Montgomery County officers arrived within moments. The people in the car were taken into custody.

K3CMY was warmly thanked by the arresting officers and the Montgomery County dispatcher for his assistance and the ability of amateur radio to deliver solid communications when the need arose.

At this time no details are known regarding the status of the man and woman who were the object of the chase.

DEEP THANKS

Mr. John Meshna
Dear John:

Please accept my deep thanks for sending me one of the last of your "mystery" calculators, as described by J. K. (Jake) Bach in the March, 1976 *73 Magazine*.

By the time I'd read Mr. Bach's article, written him my thanks for a really intriguing story, and received his delightful answer and a fascinating resumé of his background, I could hardly wait to receive a "busted" calculator from you and start to explore its innards, as per Bach.

When U.P.S. delivered your box to me, I was more than ready to pry into its lovely interior, and did so immediately.

The first step was to insert 4 "D" cells and flop it over to see if anything had happened. Voila, everything had happened! It was in full bloom and fully functional, with no open "L1" and no soldering needed.

Over the years, John, you have sent me many real "goodies," but this time you are but the keystone of a triumvirate: I have to thank Wayne Green for publishing your ad and Bach's story, and Mr. Bach for his careful research and manuscript.

MORE KUDOS FOR S. D. SALES

More kudos for S. D. Sales – great people to do business with!!!!

Your outlook on CBers is refreshing. (Even made *QST* stand up and take notice!) I found that both CBers and hams have much in common – obnoxious members who curse and just show disrespect for all who share the freqs.; great members who will give their all for someone just to help him out. Both have courteous members who are a pleasure to listen to and who this person looks forward to meeting on the airways (hopefully soon!). The greatest common link is the need to communicate!

Jim Griffin
Las Cruces NM

STOP THE PRESSES!

Stop the presses!! Stop the presses!! I got my April issue in February.

If this keeps accelerating, my brand new three year subscription will run out in August!!

Roy Rehbein WN1VHX
Hopedale MA

LOYAL ARRL MAN

Keep up the good work – I really enjoy your *73 Magazine* – it is really F.B. and tells it like it is.

As a loyal ARRL man, I sometimes get blood pressure rises, but a free press is essential for us to know all sides of every issue affecting our great ham fraternity.

Leo Scanlon WB5OJT
Vicksburg MS

HANG IN THERE

I've been reading, in various radio magazines, letters from readers complaining of the length of time it takes the FCC to process their license applications (or else they think the code requirements are too tough).

I'm writing because I think I have an actual example which might encourage these people to hang in there and be patient.

You have heard the old saying that good or bad, things come in threes.

The first thing was getting my license. After receiving my Novice license, I took the Technician test so that I wouldn't lose my call. However, I never went on the air as a Tech.

Der Repeatermeister

-- then get satellite pictures and other things

As I promised in an earlier article, here is the conclusion to the construction of a 220 MHz repeater. It is the control system I designed to operate any repeater with minimum attention. Once put into operation, there should be no need to ever service the control system, except for changing the ID.

This system consists of two main PC boards, the timer control and the ID. The timer board contains all the necessary circuitry for the complete and unattended operation of a remote repeater with provisions for timeout reset, instant dropout, and autopatch access and de-access with adjustable timers. The timers consist of two NE556s and one NE555 which are set up to control the transmit keying transistor. The timing functions are: autopatch timer, timeout timer, tail timer, ID timer, and what I call a receiver off timer.

The CW identifier is an improvement on the circuit in the *FM and Repeaters Handbook* published by the ARRL. It can be found on pages 136 and 137 (1972 edition). I didn't understand the clock oscillator and stop logic circuit, so I redesigned it to operate with the control board I had designed. However, it will function on its own quite well and will interface with almost any existing control system. Also, it's dirt cheap to build. Depending on where you get the 8223, total cost for parts is about $7.00. In fact, the whole system should only set you back about $30.00, which is cheaper than a certain CW ID kit I know of using diodes for programming.

Both boards are single-sided and four and three-quarters inch square so they may be stacked to save space. I really hate using a lot of jumper wires, but it's easier than trying a double-sided board. I admit that I'm not that good at making PC boards yet. If the boards are used separately, there is provision for using an LM309K on each; if used together, one may be eliminated and a jumper installed from the board with the regulator. Total current drain is around 400 mils, which is well within the ratings of the LM309K.

The nice thing about using a PROM is that it can be custom programmed in the field. Several magazines have published articles on programming the 8223, the best one having appeared in Popular Electronics, July, 1975, page 27. Once you get

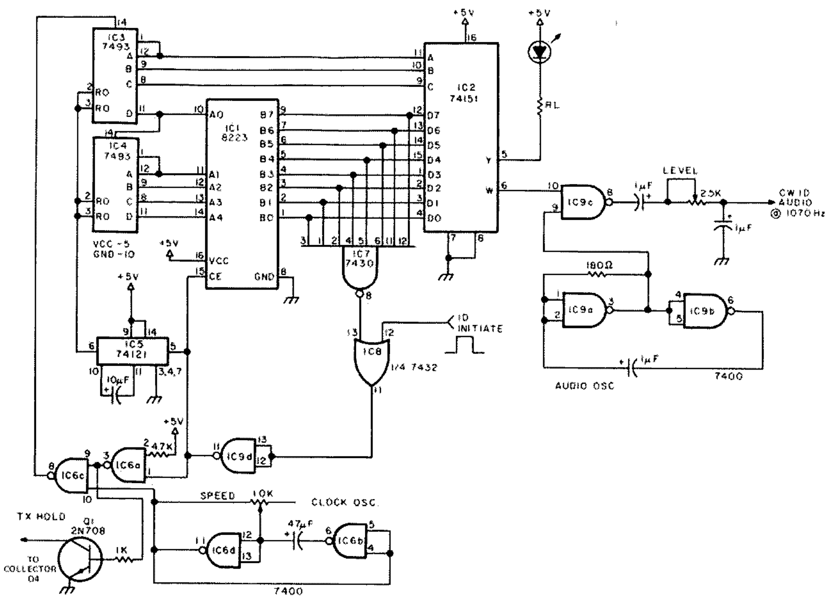

Fig. 1. PROM CW ID. Program note: Dit — 0 — Space in same letter 1; Dah — 000 — Space between letters 111; Space between words 11111 or 111111.

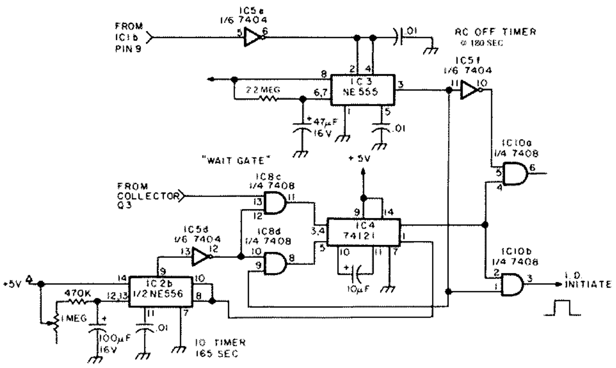

Fig. 2. "Smart" ID Timer.

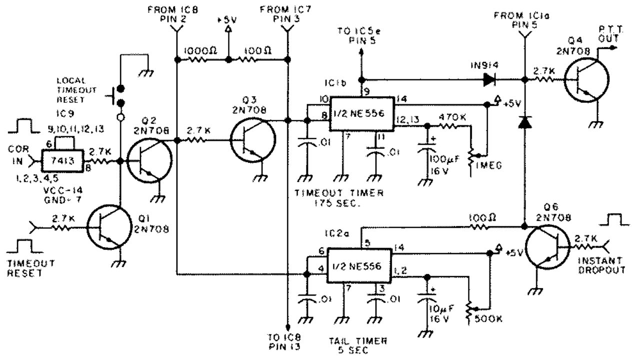

Fig. 3. Timeout and Tail Timer.

used to the procedure for programming, it only takes about five minutes to do the whole chip.

PROM CW ID

The changes made to this circuit are simple. Rather than the stop logic the original had, I used a 7430 8-input NAND gate. This chip will give a logic 0 output for all 1 inputs. The 7432 will decode the 0 from the 7430 and the 0 on the ID Initiate input and give a 0 output which is inverted by IC9d to fire the one-shot, resetting the two counter ICs to zero, and also puts a high on the Chip Enable of the 8223 which puts all the outputs to a logic 1, thus ensuring that the ID circuit stays stopped until initiated again by a logic 1 pulse.

This is very important. Program the 8223 with reverse logic. If you want a tone, the output of the 8223 must be a 0. Also, make sure that no set of outputs is all logic 1s, because this is the stop word. Try to arrange the programming in such a way that at least one output per word is a 0. Example: DE WA1UFE. Word 0 – 1000111, word 1 – 0111010, word 2 – 1011111, word 3 – 0001000, etc. The words read from right to left. That is, B7, B6, B5, B4, B3, B2, B1, B0. Of course, the stop word, 1111111, can be programmed anywhere in the chip, but should be immediately after the message.

A "Smart" ID Timer

This is the best part of the whole design. I wanted an ID that would not come on over someone's transmission, would wait until the carrier dropped, would have to ID on initial keyup, ID after a timeout, and ID once after repeater usage ceased. This one does it all.

IC2b and IC4 are connected as a self-resetting timer. But the gates marked "wait gate" control the resetting of the timer. Assume that IC3 has timed out. This puts a low on pin 9 of IC8, which puts a low on pin 5 of IC4. If there is no signal being received, pin 13 of IC8 is also low. As soon as IC2b times out, pins 10 and 12 of IC8 go high. Now the circuit is "waiting." Backing up a bit, IC3 is timed out because pins 2 and 4 see a

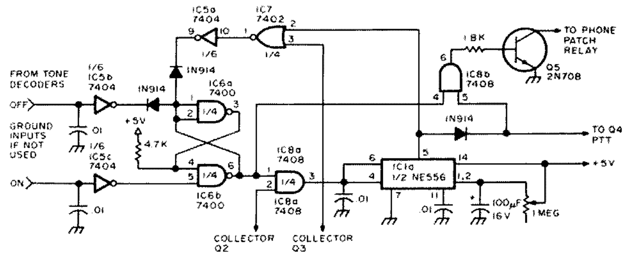

Fig. 4. Autopatch Timer.

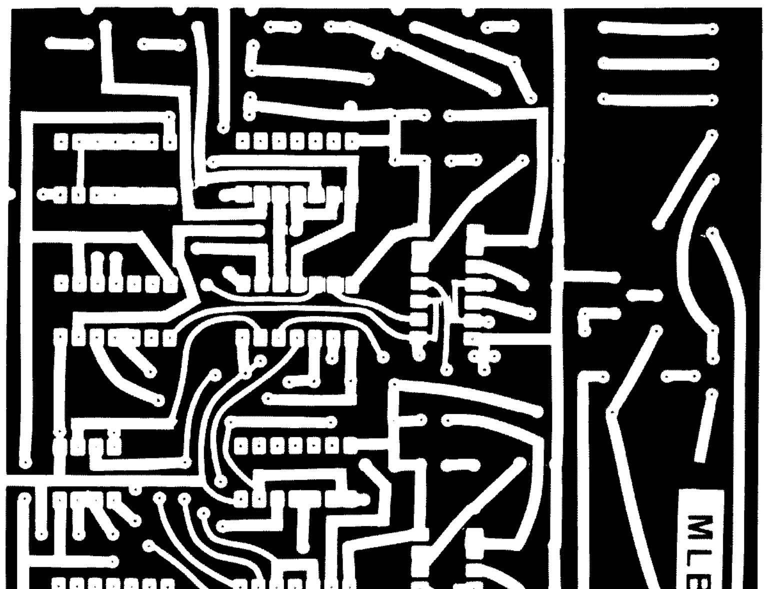

Fig. 5. Master logic board (full size).

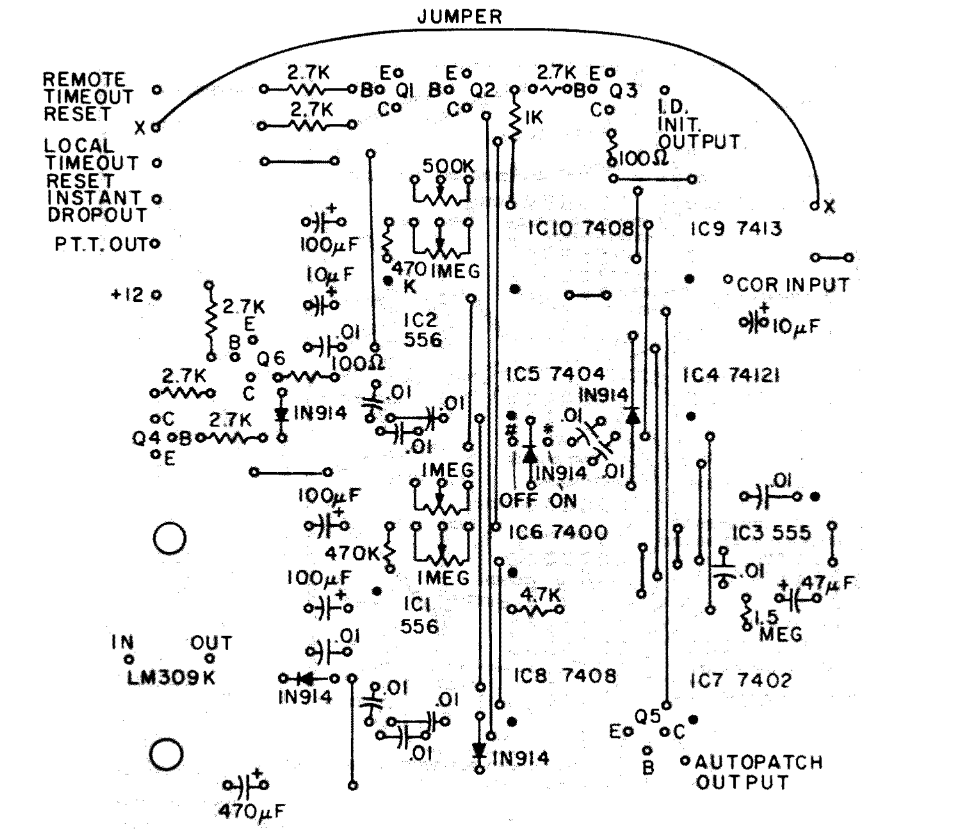

Fig. 6. Component side, master logic board. Dot identifies pin 1. Drill two small holes near input and output of IC9 and add jumper shown. Use insulated wire. Also use insulated wire for the long jumpers.

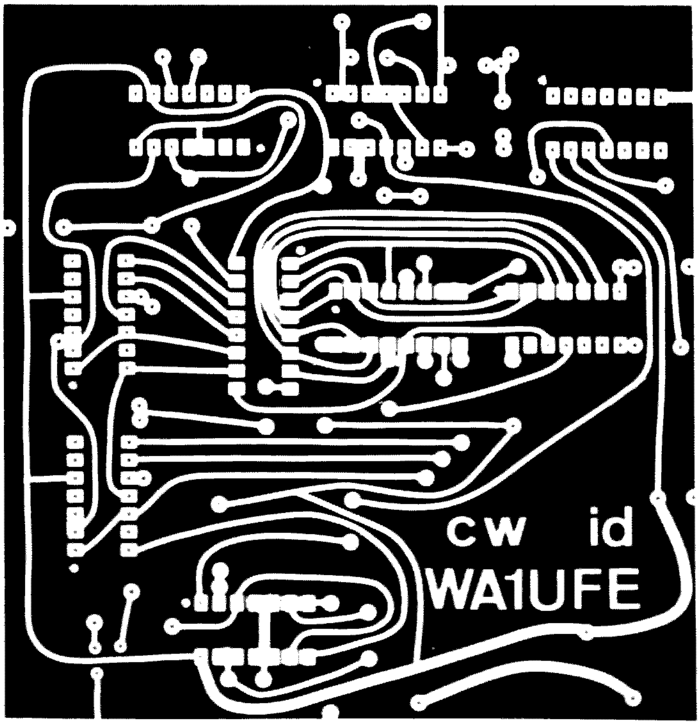

Fig. 7. CW ID board (full size).

high. As soon as the input goes low, the timer is reset, and will start timing as soon as the input goes high again. Now, suppose a signal is received. Pin 13 of IC8 goes high, and since pin 12 is high, a high is put on pins 3 and 4 of IC4. Nothing happens yet since pin 5 is still low. As soon as the signal drops, pins 3 and 4 go low and IC3 starts timing again, putting a high on pin 9 of IC8, which puts a high on pin 5 of IC4 and fires the one-shot which initiates the ID and resets IC2b. A similar sequence occurs during repeater usage, timeout, and final ID.

The reason for IC10a: I was trying to get an exclusive output for use with a voice ID circuit; logically, it should work, but practically, it doesn't.

Timeout and Tail Timer

A simple enough circuit: two timers working out of phase with each other. IC1b is set to control the transmitter on-time, which is variable from about 1 minute to 3½ minutes. IC2a is set to time out at 5 seconds and is reset each time the receiver squelch is broken. If no tail is wanted, a logic one at the base of Q6 will short the output of IC2a to ground through the 100 Ohm load resistor.

I found that I needed a Schmitt Trigger input. It seems that when the receiver's squelch is broken, the squelch gate generated a burst of noise that caused false triggering of the ID timer. Adding the 7413 cured the problem. A logic one on the COR input is needed to key the transmitter.

Q1 is used for remote timeout reset, which can be controlled from the remote control receiver and tone decoders. A short logic one pulse will momentarily ground the base of Q2, resetting all the timers.

Q4 is the transmitter

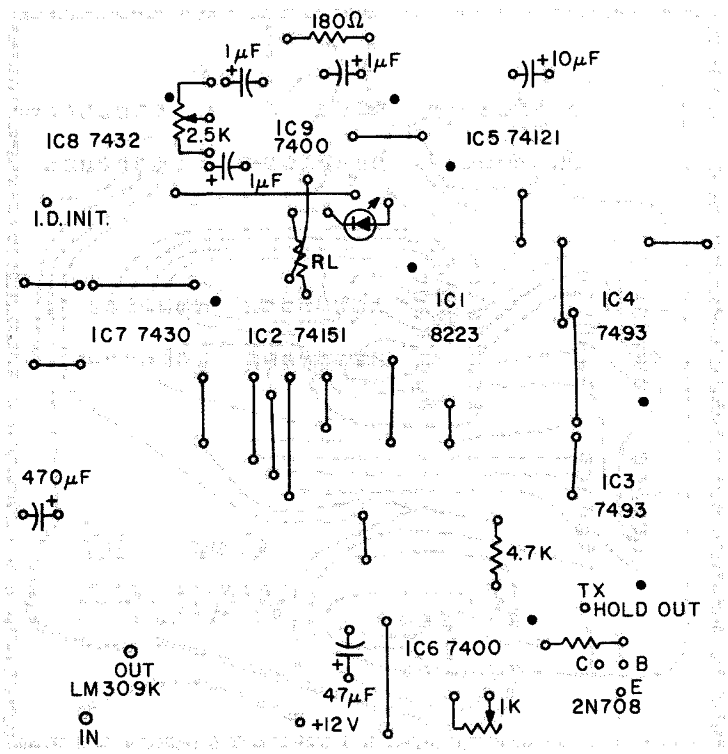

Fig. 8. Component side, CW ID. Dot identifies IC pin 1.

keying transistor. The collector is grounded when active, so this will work with relay keying or the solid state keyer I used in the repeater I built. If the transmitter being controlled uses a 120 volt relay, substitute a high voltage transistor for the 2N708 used here. I assumed a solid state repeater.

Autopatch Timer

Since autopatch is becoming more popular on repeaters these days, I decided to include a timing circuit for it, also. This circuit will allow an adjustable time delay in the receive mode (for the user). It is adjustable from about 30 seconds to over 90 seconds. If someone should access the patch and for some reason not be able to transmit again, once IC1a times out, it will automatically drop the phone line and reset itself so that one would have to re-access. The time-out on the user's transmission is limited by the normal time-out period.

Logic one inputs are required to enable and disable the timer. Not knowing what every repeater uses as tone decoders, I purposely designed it to be flexible. This will also allow any access code one wants to use, if other than * for access and # for de-access: single tone or sequential tone or whatever, as long as the circuit being used can provide a logic one output.

Not being familiar with phone patches, I decided on an uncommitted collector output. I am, of course, assuming that a phone patch has a relay in it that can be energized by grounding one side of the coil.

If this portion of the control board is not needed or not used, note that the inputs must be grounded; otherwise, the transmitter will latch on transmit. ■

Parts List — Logic Board

Lightning and Thunder and Other Stuff

-- can J. Bach be a relative of P.D.Q. Bach?

J. K. Bach
Ivy Hill Road
Walden NY 12586

For help with this story, I am grateful to C. S Daugherty, Teaneck NJ, Mr. and Mrs. Ashley, Walden NY, Barbara Gerard, Dale's Auto Parts, Walden NY, Shorty's Taxi Service, Walden, NY, E. Hassdenteufel, Telco, Newburgh NY, W. Green, Peterborough NH.

Over a hundred years ago, a father, mother and their two daughters sat before their fireplace, watching the dying embers. There came a bluish flickering in the chimney.

"What's that, Papa?" asked one of the girls.

"Wait a minute, and you'll see it again," he said.

Soon it came again, and took him with it when it went, without harming any of the others. One of the girls was my maternal grandmother, who was terrified of lightning all of her days.

Many don't know that heat ionizes air, and that a hot flue is a dangerously good conductor for lightning. An open window is not so good either — to stand in one during an electric storm is foolish bravado. A lightning stroke may be three miles long, *all of it* through air. It is well to avoid metal, but that does not, of itself, guarantee safety.

Many people get knocked kicking, or cold, by secondary or induced strokes. A lifelong friend of mine was in his house and saw a black walnut tree struck, and something knocked him down at the same time. With its bark blasted off, the tree later died. He also had a playmate who lagged behind a group and was struck in the open and killed.

Lightning deaths in this country run around four hundred a year, more or less. A thousand more are injured more or less seriously. I don't know if anyone has ever survived a direct main bolt of lightning — what they recovered from may have been secondary or induced shocks.

It often happens that a man's shoes will fly off when he is struck. Women's slippers are not very secure, but shoes, laced up, come off a lot harder. Lightning can do it, and frequently does. I think this is due to a violent muscle spasm.

If you like to investigate little understood subjects, try your own lightning investigation. In big cities, nobody knows what lightning is, except in the most general way; country and small town people have come to terms with it, and they can tell you stories . . . !

For instance, a close neighbor's wife saw a doorman struck from across a courtyard, and both his shoes flew off. He recovered quickly. Her husband's father, when he was seventeen, was struck and was unconscious for several hours. Thereafter, whenever an electric storm came up, he would lapse into deep unconsciousness, from which it was impossible to rouse him. At twenty-five, he married, and when his son was born, the baby used to drift off to sleep, or it may have been unconsciousness, along with his father. This was no catalepsy: They were both completely under. When the child was about eleven, he stayed awake. It is easy to think up explanations, but the passing years make it impossible to check. So nobody knows the answer, if there is one.

Another friend, who runs an auto supply business, saw a lightning flash at the very tail end of a storm which struck a locust tree. (These are frequent targets.) It spiraled the trunk more than once, jumped to a nut tree which was very close, down to a clothesline pulley and along the line, which was plastic with a steel center. Blankets were pinned to the line, and as she described it, the clothespins snapped off the line successively in a high arc like flights of arrows. The blankets fell. At the near end, the bolt burned out the telephone and its ground, knocked boards off the garage, set them afire, and simultaneously induced a power failure. She had to call the fire company, the telephone company, and the power company from a neighbor's phone and return to fight the fire.

What stuck in my mind was this one-at-a-time business with the clothespins, since I knew that lightning peaked out at 90,000 miles per second. So I asked about this again. She was less sure about the clothespins, but the ground was very muddy and held a film of oil and grease from parked cars. The blankets fell into this muck starting with the furthest one and continuing on down the line. If you have ever had a wash fall off a line — and I have — you believe her, science or no science. I never argue with facts.

At 90,000 miles/second propagation I defy you to see one end start before the other, but yet I have seen this many times and so have you and so have a multitude of people. Some of this is optical illusion — the strobe effect of ribbon or sheet lightning, perhaps. Some of it is imagination — you always see lightning strike *down*, even if it sometimes strikes *up*. In Fig. 1, next to the antenna, I have drawn a stroke of lightning as it was rendered in the middle of the last century. I don't know whether this was a convention, or whether it really looked this way to the artists of the day. Find an old woodcut of Franklin and his kite, and you'll see it shown that way. Not in real life though — no acute angles, no sawtooth. The fact remains that at times you *can* follow the progress of a stroke with the eye, and I don't care who says different. It is so, and I have seen it, and there was no mistake. The 90,000 miles/second is a *maximum*.

To continue, there was the local taximan. He was sitting in a dairy barn on a metal milking stool when the lightning rod on the barn was struck. He was knocked out, and when he came to, he saw a cow in a most un-cow-like position: flat on her belly with her front legs straight out in front of her, and her nose between her hooves. She recovered. Everything loose in the barn was upside down. Investigation revealed that the rod had been directly connected to the line of metal milking stanchions, which were embedded in the concrete floor-slab. The rod was properly grounded soon thereafter.

Some writer once pointed out that Franklin himself did not ground his lightning rods. The implication was that the old man wasn't very bright, which is a bit much. Old Ben is a hero of mine, and I happen to know that his first idea was to brush-discharge clouds and avoid lightning strokes altogether. But highly-charged clouds are swept along by the winds — the origin of sheet lightning, which strikes along a line that may be forty feet long. (This would give an apparent direction to the stroke even if it were near instantaneous.) There is no discharging such a cloud harmlessly except by a good lightning rod. Now Ben built an air shaft in his house, and suspended an iron lance in it (probably by strips of silk cloth, his favorite

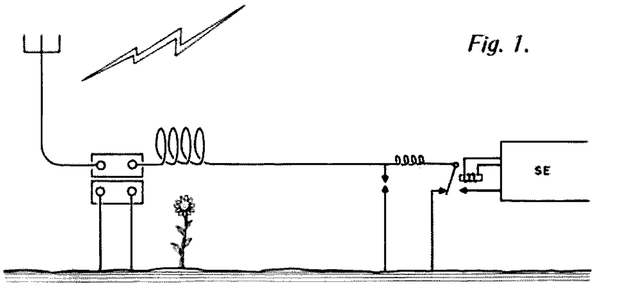

Fig. 1.

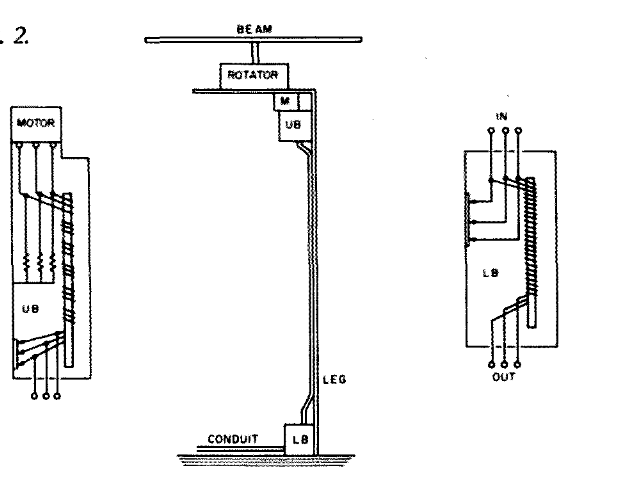
Fig. 2.



insulator) free from ground. His description makes no mention of any window, or viewing port, or peephole in this structure, but what do you think? I think he had a small window he could watch through from a rocking chair. I also think he could open this window, reach in, and charge a Leyden jar, or his own flat-plate capacitor, in fair weather from the normal voltage gradient whenever he felt like it. There is nothing in his writings to this effect, but it figures.

Franklin was no less interested in electrical discharges than any other scientist. Ask any of them. And ask them if they would attend a lecture by the old man if this were possible, and they might surprise you. As a scientist, then, he was studying discharges, and I infer that he got knocked off his chair one day and concluded that the brush-discharge theory applied only to Leyden jars. He grounded his rods forthwith. Earlier, he himself had written, "Experience keeps a dear school, but fools will learn in no other." He wasn't about to pay the tuition, himself.

Lightning comes and goes; it doesn't stick around to be studied. Aside from a few specialists, little is known about it. We not only don't know the answers, *we don't even know the questions!* When lightning strikes very close, say, within a hundred yards, there is no thunder. I have observed this myself. I also checked this with a hiker who was narrowly missed along a cliff path in the Poconos. What you get is one tremendous, ear-splitting CRACK, or explosion, and after that, nothing. No rumble, no echo, dead silence. Maybe your ears don't work very well afterward, but I have noticed the same thing with guns. Fire a thirty-oh-six or equivalent, and then listen to one across the valley and you will see what I mean. When you don't hear the rumbling thunder, you had a near miss and you had better believe it!

Sound travels at about 1100 feet per second. Five seconds between flash and thunder would indicate a mile and a little. Ten or fifteen seconds and the lightning is quite far away. But even at a mile, you sometimes get a sharp "click" simultaneously with the flash, followed by thunder later. Where does the click come from?

Obviously it comes from a pole transformer or lightning arrestor on a nearby highline, and you can hit one of them with a rock from anywhere. Nearly anywhere: Once I was really in the country, a storm came up, I got the flash/click with thunder following, and there went another perfectly good theory. I could see the nearest highline miles away.

During WW II when the 243-type air-spaced crystal holder was being developed, it was found that some plates would oscillate well in some holders and not at all in others. It was theorized that the defective holders had the wrong number of acoustic quarter-waves in them; they were redesigned, and were worse than before. After a lot of careful checking, it was determined that the sound waves had *twice their normal velocity* under the observed conditions. The formula was revised, the electrodes spaced accordingly and 243s were turned out like popcorn. So! *Two* different velocities for sound, eh? Let's call ordinary sound wave propagation O.S.W.P. and the more rapid mode, a *percussive* propagation. The O.S.W.P. takes advantage of the mass and the elasticity of the medium and is propagated very efficiently, but somewhat slowly. The percussive mode is explosive; it is driven outward from the source without regard to anything but its own force. It is not an efficient mode, since it is very rapid, and it is quickly attenuated. Does that fit the facts?

I saw an interesting submarine movie once. The boat was taking a real depth bombing. First a sharp "click," a wait, and then "Boom!" An officer explained to a passenger that the click was the detonator going off, followed by the boom of the main charge. You could tell if the explosion was near or far by the interval between the click and the boom. Sound familiar?

I have handled enough dynamite, and reloaded enough cartridges in my time to gag over the idea of an interval between detonator firing and the explosion of the main charge. Properly rationed, there is enough silliness here to supply a man for weeks. *There is no interval* between them, none that you could sense. The propagation speed of the explosion is what? – about a mile a second? – something like that, and all this stuff is together in one big drum. Having little faith in movies and their sound effects, I consulted a submarine expert I know – he has survived many depth charge attacks. He says no, it doesn't sound anything like in the movies, but yes, there is this click-pause-boom business, just as described. I haven't read anything about it, or talked about it to anyone, but again I infer that this is more of the same – O.S.W.P. and (percussive) P.P. with the percussive arriving first, but the ordinary sound wave following, and both starting at the same instant from the same source.

What's important about this? Maybe nothing. It could be important; I don't know, you don't know, neither does anyone else. But if it exists, someone should know about it. It is worth discussing.

The Encyclopedia Brittanica has a lot to say about lightning, and much of the information comes from the States, surprisingly enough. The Americana and the Collier's also have interesting sections. It is said that a lightning stroke has a diameter of 20 cm or about eight inches. What's wrong with that?

This: A flagpole is typically eight inches through. You can see the flag quite a distance, but the pole soon becomes invisible. You *know* that anything across the river is at least three miles away – still, lightning seen over there is no mere fiery thread – it has a most definite width, maybe a couple of yards across. This you can see.

Ever watch a searchlight beam on a foggy night? It goes up and is blunted like a finger, stops quite abruptly. Even as seen from the side, you get some of this effect. It

should taper off gradually, but it doesn't. Maybe that is why lightning looks so wide?

No, I don't think so. The encyclopedias tell us that the temperature inside a bolt is a little higher than that of the sun's surface, and certainly its brightness approaches the sun's also. Then it should look several times fatter than it does with *that* much light, if the finger theory applies.

I picture lightning as twisting and squirming around in a six foot tunnel of near-vacuum and high temperature and glaring light. Maybe the individual bolts are only eight inches across, but they succeed each other at very short intervals and pretty well fill the tunnel before the bolt subsides.

But no one will ever look down such a tunnel and see what I have described. Airplanes are sometimes struck by lightning, usually without harm other than a small hole burned in the skin of the plane. Pilots have said that the first time was terrifying, and the second, worse.

Why worse? I dismissed the subject, as you probably have, until this writing. The answer undoubtedly lies in the fact that the glare is so bright that the pilots can see nothing for five minutes or more – not outside, not instruments. Turbulence prevents hands-off flying, and currents of several thousand Amperes can magnetize and burn out almost anything. I shouldn't think the autopilot or radios would work very well. But the main thing is that, from any altitude, a modern plane can get *below* ground level in less than any five minutes. I think I'd give up flying, if I survived the first bolt.

We ought to get something practical as well as educational out of all this. OK, lightning arrestors. They are very old, not so old as the lightning rod, but in wide use on power lines at the turn of the century. Simple gaps have been sold as "lightning arrestors" for radio receiving antennas for a half century, but a simple gap is only half an arrestor.

When I worked for Ma Bell, I worked with a New York Tel man who had been an installer. He had a lightning trouble to fix, so he went to the house, replaced the drop wire which was shredded, and then looked for the arrestor. Now this is a book-sized slab of glazed white porcelain, with two long skinny fuses on top, and a metal screw can, which covers two carbon gaps which are the main arrestor. It was supposed to have brass terminals on it, too. Apparently the bolt had made sand of the base and vaporized the metal, since there wasn't a single piece of the thing to be found – not a sliver the size of a fingernail. The subset inside was in perfect order – he made sure of this.

By the way, the Brittanica has a line drawing of this lightning protector together with a brief description. The output of the protector (arrestor) where it goes into the house has the wires bent into a "drip loop" which is the subject of much discussion among installers. Eddie, my friend, surmised that this loop, besides dripping water off, made up half a turn of inductance, which was somehow responsible for keeping lightning bolts out of houses.

I agreed with him without reservation. It is a very low inductance, some fraction of a microhenry. Lightning is pulse stuff which seems to have an equivalent frequency of at least a megacycle. At that frequency we shouldn't expect much inductive reactance, but wait – the wave front of lightning is an extremely steep one. We are used to thinking in terms of a square wave of a few volts on a CRO. End to end, a lightning stroke may approach a BILLION volts, and there is one hellacious difference between rising six volts in a microsecond and rising, say, twenty thousand or more. Now, it doesn't have to equal the lightning voltage very far, only until the gap breaks down. Once this is well ionized, you have a pretty good short circuit and the inductive reactance is unimportant.

So far as the ground path is concerned. But it amazes me how people forget that in order to work, the inductance *must* have some current in it. (Heck, they mostly even forget to include the inductance!) What does this mean? It means that 99 44/100% of the bolt goes straight to ground, while 56/100 of 1% makes burned toast out of the front end of your transceiver or whatever. You just HAVE to account for this 0.56% because it is 0.56% of a lightning bolt, and may be sizable.

What then? I show, in Fig. 1, another arrestor at the station equipment which is not actually installed, but should be. Backing that up is a relay which is energized as long as the equipment is turned on, cutting the end-fed antenna straight through, or grounding the antenna on its back contact when released. I don't have that installed either, but I'm going to have. I have seen receivers with the front end burned up and I don't want any.

I said that nearly everybody neglects the inductors. But look for them in Telco and Powerco installations. And Radio Broadcast Transmitters. I worked a couple of years for a local BC station. Their coax cables are as big as your wrist, and the "drip" loop, or inductor, is three turns or so, each a yard across. The end is connected across the base insulator, and in parallel with this is the lightning gap. It looks like a piece of heavy strap iron, grounded under the base insulator, with a bolt at the top that faces a tower leg, spaced no more than an eighth of an inch away from it.

One morning, as the FCC requires, I was reading the antenna base currents and logging them, when the lightning gap caught my eye. While it looked heavy enough to swing on, I was a little cautious – I reached out and tapped it gently with the edge of my shoe. Not like Kojak entering an apartment, but rather gingerly. I got a big, bright, hot arc that stood for five long seconds and went out. I loped back for the transmitter at my very best lope but everything was OK; the tape was still running and there were no telephone calls. Nobody listens! I concluded that the strap was several laminations of sheet copper painted black. I know it was flexible and not very springy.

Another man I worked with had a farm, and used fence "controllers" for cattle – i.e., an electric fence. Lightning got this thing every couple of weeks and he needed a new one, or extensive repairs. I mentioned the drip loop and he wound about ten turns at the controller terminal. No more trouble.

My own lightning arrestor is for an end fed 80 meter dipole. Most lead-ins are 50 Ohm transmission lines, but this poses no problem at all. Just wind the whole business, center conductor, braid and all, in a coil. It won't even add an irregularity to your line. Maybe a gap will, though there is a coax fitting with a built-in adjustable gap that is supposed to be OK.

But how about transmitting through such a device? Wouldn't it need a gargantuan gap? Let's see . . . for a 50 W line at 2 kW Peak Envelope,

$$P = E^2/R$$
$$E^2 = PR = 2 \times 50 = 100$$
$$E = \sqrt{100} = 10$$

which I don't believe for a moment and I hope you

don't either. Obviously I'm suffering from a lack of coffee.

Ah! Much better!

$$E^2 = 2{,}000 \text{ (ah-HAH!) } \times 50 = 100{,}000$$

$$E = \sqrt{100{,}000} = 316 \text{ volts}$$

or some such, which is a lot more reasonable. I have heard the figure 8,000 volts breakdown between needle points. Spark plug gaps are a great deal shorter than this, but remember they work under high pressures. So it looks like the little fitting I spoke of will work for a full sized ham transmitter. If it doesn't, and you have to introduce a larger one, which makes an irregularity, remember please, that lightning makes lots bigger ones.

Fig. 2 is about rotators and their wiring. I don't have one of these, but if I did, I should protect it as shown. The box does not have to be steel, but steel is nice. When lightning goes down that leg to ground, there is an enormous magnetic field produced. There is no way to shield the wiring – all you can do is "drip loop" and gap it. At the motor end, I have shown some resistors to ground. These are high enough not to affect normal operation, but at the same time afford a lightning path to ground besides that of the motor insulation. I have a feeling that the windings will break down pretty easily unless there is protection. As I say, I don't own one, so this is all theory.

We don't know the whole story about lightning yet. As a child I lived across the river from Cincinnati. One evening I was treated to a celestial fireworks display like no other I have seen or heard of. So far as I could see, there was not a cloud in the sky. The arc in the lone streetlight in our block sputtered and clinked, but the lightning outshone it making it negligible. Starting at the southern horizon, the bolts crawled across the sky to the zenith, like the fiery hands of God reaching . . . reaching . . . for whom? For a frightened little boy (me), guilt-ridden as all of us then were? Not to feel guilt continually was surely arrogance, which was something else to be guilty of. Nevertheless, I watched as long as I dared, because there was no slightest sound, save the beating of my own heart and the clinking of the arc light. The lightning was completely silent, and as spooky as anything Hitchcock ever dreamed up.

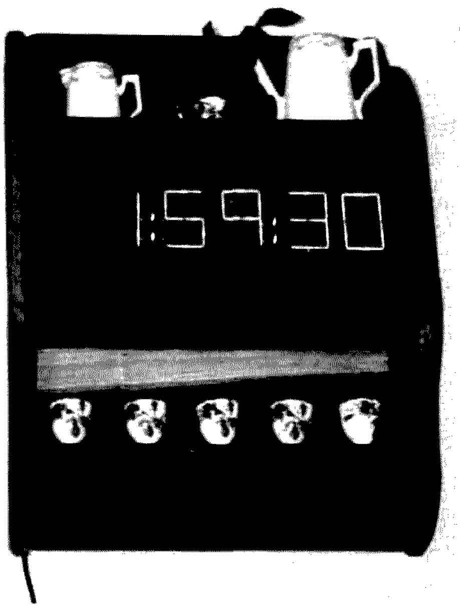
I asked my parents about it. "Heat lightning," they explained. It was so far away that I did not hear the thunder it generated. Far away? Straight up? And if you look up definitions you will find exactly that explanation in modern books.

In 1885 the Washington Monument was struck several times on one occasion, and several observers testified that the strokes were absolutely noiseless. The Empire State Building often has noiseless strokes. Here it is theorized that the upward "stepped leader" was not followed by a main stroke (they don't say why) so that the violent blast is missing.

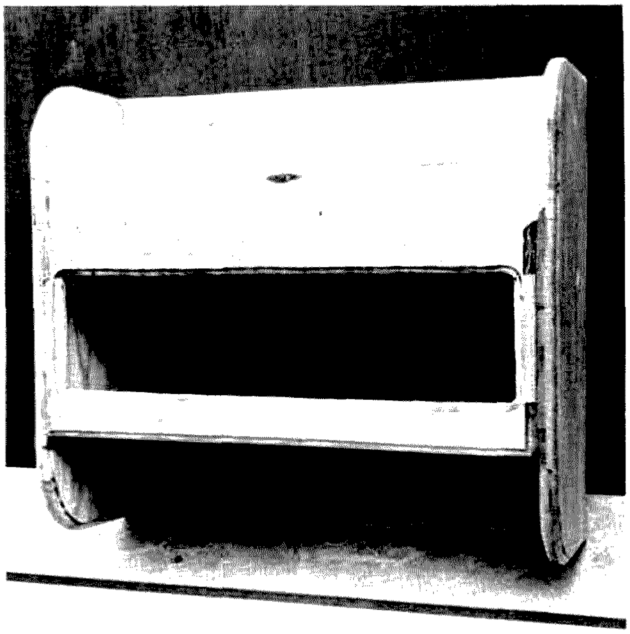
The Brittanica also mentions that a length of #14 AWG rubber-covered wire was struck by a bolt, which in some fashion completely removed the wire, leaving a tube of rubber intact. They don't say how long the wire was.

Apparently someone had doubts about all this, so he set up an experiment with the same kind of wire (Dammit, how *long* was the wire? It makes a difference!) with exactly the same results – the artificial lightning either vaporized or melted or punched out the wire insert leaving a rubber tube, intact.

I have succeeded with this story if I have convinced you only that *lightning is nothing to horse around with!* ■



Completed wall clock with two whatnot shelves.



Another cabinet "in the rough," ready for sanding, finishing, and the works.

Behold the Giant Nixie Clock

--using a minimum of new parts

Jack Grimes W4LLR
P.O. Box 16004
Memphis TN 38116

The May 1975 issue of *73 Magazine* contained the article "Fat Nixies For Chronometer Nuts." I'd tip my hat, if I wore one, to anyone who makes use of a surplus bargain, and the Burroughs 7971 alphanumeric tubes are a steal on the market at the present time. When used as the display for a six digit clock, they become an eye-popping conversation piece.

Having accumulated a sizable stock of the giant nixies with clocks in mind, the *73* article was a welcome sight and inspired me to get out the old soldering iron and dust off the workbench (that is if you can call four layers of assorted junk, including, but not limited to, resistors, condensers, wire, metal drill shavings, transformer laminations, etc., "dust").

My giant nixies were acquired complete with the sockets and brackets mounted on boards. Each assembly includes two nixies, two sockets, 33 transistors, about 100 resistors, 25 diodes and 18 capacitors, plus wire.

Before I began work I reached for the Radio Shack catalog to look up the price I would have to pay for the RS2008 300 volt NPN transistors specified in the article. It quickly became apparent that the $5.00 paid for the three boards (with six nixies and sockets) was only a small down payment on the finished product. Another bottleneck (at least to me) was that a quick look through the latest flyers in the shack showed no readily available source of PNP 300 volt transistors at any price. (I never did get around to writing Heathkit.)

Since I had ordered nixies to build seven of the clocks for use as gifts (for people

who seem to have everything), I was somewhat reluctant to purchase the necessary 448 resistors and 175 transistors, when half or more of the little solid state devices would be costing upwards of $1.50 each. Besides that (now we get to the nitty-gritty), the pocketbook was slightly flat!

So I kept staring at those surplus boards with those 33 transistors in nice shining rows, and all those other parts. And I kept looking at the May 1975 issue of *73 Magazine* and at the spec sheets which came with the MM5314 clock chips. At one time, I reasoned, those same 33 transistors *had been used to drive the nixies.* So why not use them in the nixie clock?

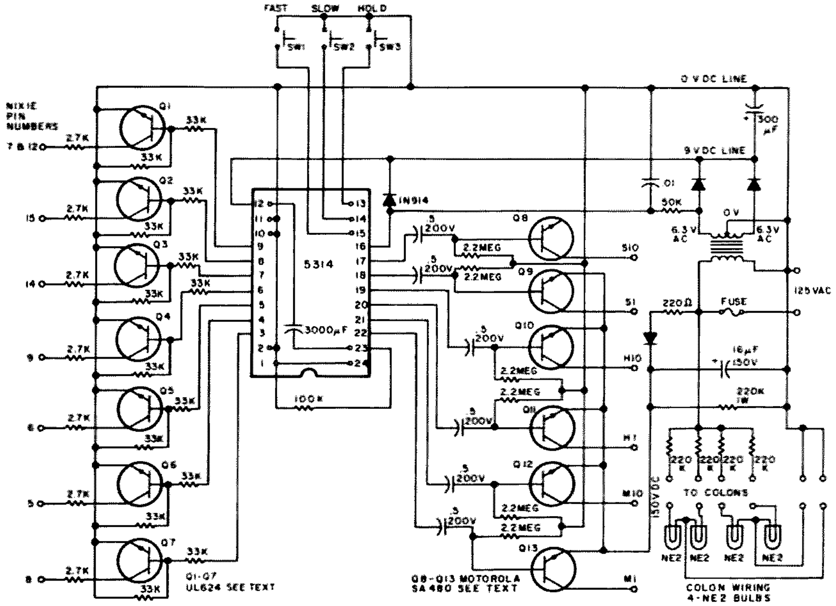


Fig. 1.

It was easy to determine that the long row of transistors farthest from the brackets had been used as segment drivers (UL624). Two transistors located at one end of the board, approximately two inches behind the only 2 Watt resistors, were determined to be PNP high voltage type. Most are Motorola SA480. A few boards used Texas Instruments, designated UL480.

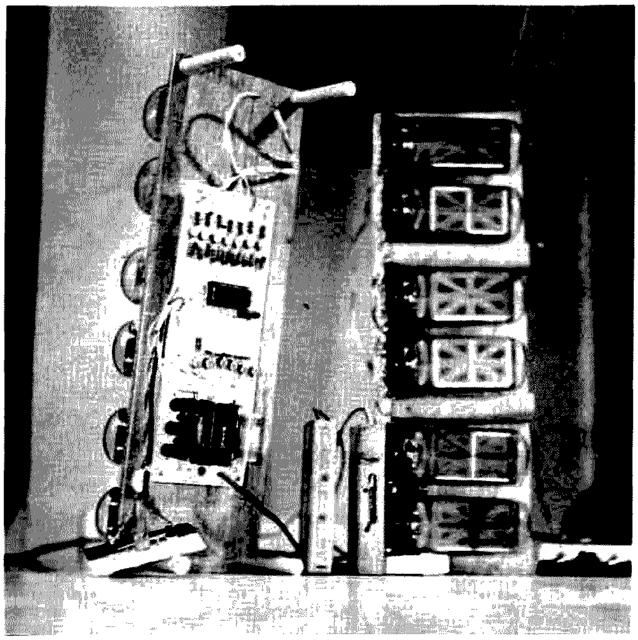
But I had no way of knowing how high the voltage rating was. I am sure many readers have access to books and could easily obtain the specs, but nothing I had gave the information, and inquiries among friends and on the nets failed. So I crossed and uncrossed fingers and began experimenting with the following objectives in mind:

1. Build a clock using as many parts as possible from the surplus boards.

2. Simplify the design and eliminate as many parts as possible.

I am happy to say both objectives were more successful than I dared hope. All transistors were taken from the boards, as were a large number of resistors. Even the board itself, with PC strips removed by sanding, is used as the "board chassis."

The total number of parts has been cut approximately in half, resulting in substantial savings even if the nixies are bought less boards and it is necessary to purchase transistors. As examples, my clocks use only 13 transistors rather than 25 as specified in the *73* article, only 27 resistors in circuits associated with the driver transistors compared to 64, and the power supply has a total of 3 diodes instead of 8 and 2 resistors rather than 4. At the same time, sharpness, clarity and brilliance of the numerals leave nothing to be desired.



Two clocks, ready for cabinet, standing on end. A pair of colon blocks, viewed from the front and rear, stand between the clocks.

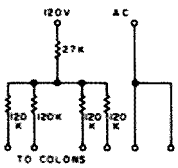
The construction of the clock is straightforward and not difficult. It actually is built in three phases or parts, which are then brought together for the finished project: the display, the brain-board, and the cabinet.

A cabinet may be built of any material for wall mounting or for table or rack. A good grade of full one inch oak, birch, walnut or maple, etc., will make a cabinet worthy of the "works" you will build. My choice was wall clocks of wood. Once this decision was made the rest of the construction fell into place.

Since the cabinets were to be of wood, it was natural to mount the nixie socket-brackets on wood. For this purpose cut a piece of plywood or ¾" plank 16½" long x 5¾" high.

The brackets are removed from the PC boards, leaving the sockets intact, and sawed off just toward the center from the mounting holes. The two bracket ends containing the sockets may now be bolted together using the existing hole. The three boards will yield three pairs of bracket-sockets, for hours, minutes and seconds.

Fig. 2. Alternate colon wiring, enabling use of resistors from boards.

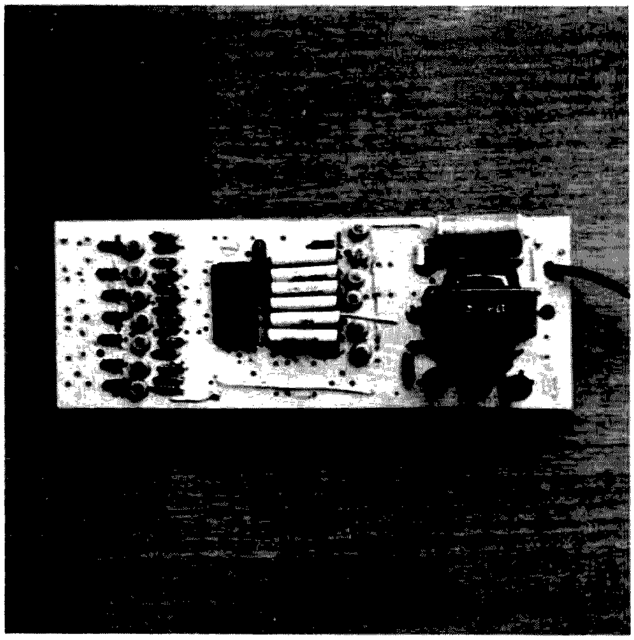


Mount with short wood screws along the bottom of the wood strip, leaving approximately one inch between pairs. (Colons will be placed in these gaps.)

You are now ready for some wiring fun – multiplexing the segment pins. This simply means connecting all like pins together. Wire only the pins used, of course. (See page 24 of the May 1975 issue of *73 Magazine* for details.) The wires should be formed to run along the back of the sockets along the bottom edge of the wood. Use seven color coded wires; a cable is formed approximately one foot long which is passed through a ¼" hole to the back of the wooden board. Six wires, also color coded, are wired to pin 13 of each nixie and are also brought to the rear of the plank.

Two colons are made from four NE2 neon bulbs. The NE2s are mounted in shallow ¼" holes drilled in two wooden blocks which hold the lights approximately even with the surface of the giant nixie display. With a small bit, drill two separate holes from the bottom of each shallow hole through to the back, for the NE2 leads. A ¼" hole is drilled from the bottom end of each block near the back and allowed to "come out" the back midway up. In this manner the leads of the NE2s may be reached and connections made. Three wires are brought out the bottom (one common and one to each bulb). This wiring is cabled with the segment wiring and also brought to the back of the display board.

The NE2s are fed from the 120 volt ac line through four 220k resistors, which gives the proper brightness to match the display.



Top view of board. Transformer is mounted with half below the board. The three black spots below the transformer are three 100 uF filters, 25 V rating, paralleled. Segment drivers are at one end of the board. Digit enable is near the center.

Bottom view of board. Resistor above the transformer is the H. V. bleeder.

If it is desired to use parts from the board, four 120k resistors may be used, one to feed each NE2, and one 27k resistor to feed the four resistors. See alternate colon wiring.

With the display complete you are ready to tackle the "brain-board." There is no question that a printed circuit board would be the ideal way to wire the clock. But not having PC facilities and desiring to build only seven clocks, it seemed sensible to proceed with freehand layout and drilling. Actually I use old PC boards with the strips sanded off with a rotary sander.

The power supply should be wired first. A 12 volt center tap filament transformer allows use of only two diodes. However, a 6.3 volt transformer with a bridge does an equally good job. You should come out with approximately 9 volts dc for the clock chip. At this voltage the chip does not run even slightly warm and operates perfectly.

Experiments showed the giant nixies fire with a voltage much lower than the 180-200 volts. Using a lower voltage gives a safety margin for the high voltage transistors.

In the interests of cost and simplicity, a simple half wave circuit is used to rectify the line voltage for the 150 volt supply. A 16 mF capacitor with at least 150 volt rating is sufficient filtering. A 220k 1 Watt resistor serves to bleed off the voltage slowly when the clock is unplugged.

Writing this, I can almost hear the screams: "A line voltage rectifier! A hot chassis!"

Well, this clock has *no hot chassis*, because it has no (metal) chassis. Note in the diagram there are no ground symbols. Only a "0" volts dc line. This same line has one leg of the 120 V ac on it. But, kept completely under the board and enclosed in a wooden cabinet, it certainly does not present a shock hazard.

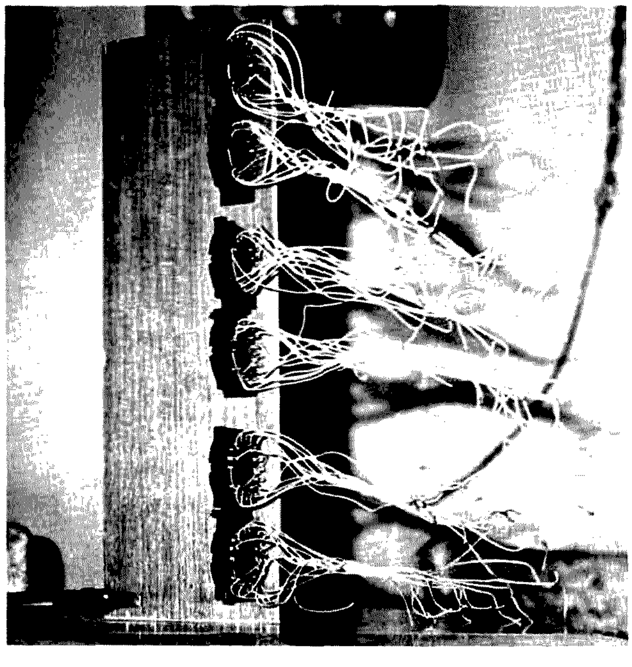
Once the power supply is complete and tested, the clock chip socket should be mounted in the approximate center of the remaining board space. Then mount the components, and wire everything

The bracket mounting, wiring, and colon mounting.

associated with pins 2, 10, 11, 12, 16, 23 and 24 of the chip. At this point, if you wish, you may install the chip and apply power.

Using a scope, if all is well, you should see pulses appearing on pins 17 through 22. If you do not have a scope, a VOM may be used and you will get a pulsing, variable reading on the 12 V scale from pins 3 through 9.

The segment drivers use the UL624 transistors from the surplus boards. I have never had one fail, even while experimenting. Only six of the 33k resistors are available from the boards. However, I have used 20k resistors from the base of the transistors to the IC chip with no noticeable change in operation of the clock. So this does not appear to be critical. Because of the much lower voltage and shorter duration of the pulses, 2.7k resistors are used for current limiting – all from the surplus boards.



Tube sockets and brackets after removal from surplus boards and mounted on wood strip. Wires are left attached and used for multiplex wiring.

The tricky part of the giant nixie clock, as mentioned in the May 1975 article, is interfacing the digit enable pulses with the high voltage transistors. It is, of course, an absolute must to keep the high voltage isolated from the low voltage chip, while at the same time passing a pulse of sufficient intensity to trigger the transistor and provide the voltage to light the proper segments of the nixies.

Fortunately such a device to do this is in existence! It was invented quite a number of years ago. This needed device is called a capacitor.

My first effort was to use the .022 condensers on the surplus boards between the chips and base of the high voltage transistors. If one turned the lights out in the shack, flickering numbers could be seen.

An 8 mF filter, + side to the base of the transistor and connected across one of the .022 capacitors, lighted a numeral brightly. But six 150 volt filters would not be exactly cheap or space saving. And the numeral had a tendency to pulse.

Any old-timer and most new hams know it takes a very large capacity to pass a low frequency, while a very small capacitor will pass a high frequency.

So, why not raise the multiple, or scanning rate, thereby increasing the frequency and shortening the duration of the pulses? Hence the 3,000 mmF condenser in the frequency determining portion of the chip circuit. With this scanning rate, .5 capacitors pass the pulse nicely. With this problem solved, building a clock became a matter of mounting parts and wiring.

One word of caution: Be sure and short the leads of each .5 condenser together before installing to be sure there is no residual charge. A capacitor holding a charge, if connected to the chip, can knock out the device.

When first firing up the clock, you may feel something is wrong as not all numerals will necessarily light. For some reason the first digit usually comes up a "3," and the other numbers will probably not make sense. But the seconds should be counting. Press the fast forward button and run the clock through a full 12 hours. If all is well, it will straighten out and the sequence will fall into place.

Building the Cabinet

For those who may wish to duplicate the wall clock, I will give the cabinet dimensions. Whatever type cabinet you decide on, the inside space will have to be large enough to accommodate the 16½" length and approximate 6" height and 5" to 6" depth.

My cabinets are built from 1" wood and overall dimensions are 24" high, 18½" wide and 8" deep. The top of the clock forms one shelf and is 7" deep. The bottom shelf is 3" deep. The wood is finished only with Formby's Tung Oil and hand rubbed – no varnish.

There is no special grooving. Only two side panels, shelves and back, cut to fit and put together with dowel pins – no nails. A piece of glass is placed in front of the nixies, as are two 2" wide pieces of trim, reducing the opening to approximately 4 inches.

The cabinets are cut out entirely with a circular and a saber saw and finished with a sander. The only special work

is rounded corners and a groove for the glass, courtesy of a neighbor's router.

So-o-o, if you haven't already taken the plunge and built a really glamorous digital clock, why not? You'll have fun and the clock in the house (not the shack) is guaranteed to earn you plenty of brownie points with the XYL. She just might decide all that electronics knowledge you've been soaking up is worth something after all! ■

For those who may purchase the nixie tubes less boards, or have bad PNP high voltage transistors on a board, a source of a high voltage PNP transistor is RGS Electronics, 3650 Charles St., Suite K, Santa Clara CA 95050. The designation of this transistor is "P-8," the voltage rating 150 V. I have used this transistor completely in one clock and the results were perfect. The numerals were somewhat brighter. It was necessary to increase the capacity of the frequency control condenser when using this transistor. Cost of the "P-8": 30 cents each.

RGS also has several NPN transistors suitable for segment switching.

I have been substituting quite freely the resistors which are connected to pins 3, 4, 5, 6, 7, 8 and 9. Values as low as 15,000 Ohms work very well. The boards have a large number of these resistors on them. Also, the 33k resistors to ground (from the bases of Q1-7), are not critical. In general these resistors should be of higher value when substituting, while the resistors between base and IC should be substituted at a lower value. Of course, all substituted resistors (either string) should be of the same value, i.e., all 15,000, etc.

I have completed five additional clocks since writing the article.

Creative SSTV Programming

--how to put pizzazz into your show

Ralph E. Taggart WB8DQT
4515 Oakwood Drive
Okemos MI 48864

Slow scan television can, without a doubt, add the single largest new dimension to amateur radio activities since we started using phone. Unfortunately, the way in which most of us have used this new mode is far from creative. The advent of new operating conveniences such as keyboards has not improved matters; in fact, many "video" exchanges have degenerated into nothing more than typed exchanges which could be accomplished just as easily with RTTY. The goal of SSTV operation is to add a visual dimension to a QSO, and if the miracle of picture transmission fails to add anything new to the "rituals" we perform on the air, we have achieved little beyond acquiring a rather expensive novelty. There are a few creative SSTV operators around – you can recognize them because their exchanges are lively and interesting without having to resort to magazine centerfolds to keep your attention. Such a level of operating does not come about simply by acquiring gear – it takes considerable time and attention and some practice to develop operating and programming techniques that will raise you above the teeming crowds. The purpose of this article is to acquaint both new and seasoned SSTV operators with some of the ideas and techniques that will help make your pictures worth watching. Let's look at some of these and see which might be applicable to your situation.

The first area to consider is programming – what do you want to show? If the name of the game is working DX or simply seeing how many stations you can work, then it hardly pays to spend good money on a camera. Simply get a keyboard and start typing. Your countries total will mount but the QSOs will be as sterile as the typical impersonal exchange that marks so much amateur operation these days. Of course you will want a selection of ID slides and test patterns for calling CQ, 73 and all that jazz. We can also throw in ourselves, but few of us are good looking enough to keep up interest with that sort of material! There is, of course, all that gear that you have so lovingly assembled, but let's face it – my SB-102 looks very much like yours. Even if you have a piece of gear that I don't, it is

probable that I already know what it looks like, otherwise the advertisers are wasting a fortune in promotion! Your shack – the way you have piled all the junk together – is probably unique and a picture of this can substitute for a visit. Unfortunately, the roster of material in most stations runs only this far. This may thrill you to death if you are new at the TV game, but the prospect of facing nothing but such material on a Saturday afternoon when you have been in the game for a number of years is enough to make you leave the rig off and socialize with the wife and kids.

What about the wife and kids? They rank high on my list of subjects simply because they acquaint people with the family – just use them in moderation remembering the family movie syndrome. Are there other horizons? What are your interests? Are there non-obscene topics that turn you on? A photographic tour of the points of interest in your area adds a personal touch. Subjects such as a new model plane or anything from your other hobbies also brings you a little closer to the op at the other end. How about pictures from the last vacation or telling a story with pictures? The chances are the guy at the other end is used to watching endless streams of video trash; provide him with an interesting program, and at least you'll get a star in the log and maybe a friend for life! There are some people who are too busy to watch an interesting presentation. If you happen to get one of these, simply slip him your ID or type his call letters, maybe jazzed up with your leering face. He'll go away happy and the best part is that the QSO won't take much time! You can't get lessons in creativity, but look around you with the idea of saying something with pictures that you couldn't get across on phone. If you start thinking that way you will be on the right track.

A second major factor in SSTV operating is the way you use your equipment. There are several aspects to this area, some aesthetic and some technical. The technical part is easy – make sure your pictures have adequate video "swing" or contrast. There are many ways to insure this, including the WØLMD spectrum analyzer (*73 SSTV Handbook*), my own approach to budget signal analysis (*73*, January 1975), and some monitors such as the Robot and Venus which now come with spectrum analysis capability. Even pedestrian pictures look better when the camera is properly adjusted to provide a good video swing. The aesthetic part of programming concerns goodies such as lighting, camera angles, sequencing of video sources, etc. Let's look at some of these.

One of the most apparent shortcomings in most SSTV operations is the matter of lighting. The most common practice is to mount a floodlamp over the camera pointing in the general direction of the operator and hope for the best. In a typical larger room or one with dark walls, the result is a pale face floating in a sea of black – far more suitable for halloween than an exchange of pleasantries. Unless it can't be avoided, never use a single light source for primary illumination of the subject – the result will be harsh and far from pleasing. A simple light bar mounted above the camera and having at least two floodlamps is the minimum light installation you should consider. If the room has a light-colored ceiling, try "bounce lighting" – directing one or more lights at an angle toward the ceiling to provide more even illumination. If the camera can be arranged to view you against a close wall or the gear – fine – but if there is considerable distance to the nearest light surface, the background will appear black. A neat solution to this problem which I saw at W7FEN's installation was to mount a light-colored window shade on the ceiling behind the operator (as viewed from the camera). When you want to transmit live pictures, simply pull down the shade to provide a lighter background. The shade can be left up and out of the way when not in use. If the shade will be quite close to you, it should be grey, beige, or a distinct off-white color to prevent saturation of the background. If it will be located slightly further back from your normal seated position, it can be white to compensate for the additional distance. Here's another hint that as far as I know also originated with W7FEN. Control the intensity of your lights with a light dimmer or motor control. This will eliminate the need to get up and fuss with the camera f-stop; you simply dial in the light intensity required for good picture rendition. Camera and lighting angles are important as well. Profile views of the operator are generally not as pleasant as full face views – as much as people might admire your chin they still like to meet you face to face. Ideally the camera angle should be just slightly oblique along with the lights to emphasize facial contours. If strong shadows exist, fill them in with supplementary lights; light shadowing is pleasant to view, but you don't want your face to look like a lunar sunrise with extremes of light and shadow. Try to set up the camera position so that it is equivalent to someone sitting in the shack; avoid extreme camera angles. No one likes a view that looks like it originated from the ceiling, while a view of your face from the vicinity of your navel is equally unsatisfactory.

There should be less trouble with pictures of equipment and other features of the shack, for you can make these at your leisure and put them on tape for later replay. Use good camera angles and arrange lighting to avoid extremes of light and shadow. Hauling a camera around the shack during a QSO as a sort of guided tour is to be avoided like the plague. First of all, you rarely make coherent conversation as you are lugging everything around; secondly and perhaps more important, the pictures you produce this way are likely to be poorly lighted and composed. It is much easier to do it right and commit the pictures to tape, using them again when required.

For general operation, cassettes are probably the most flexible program medium. If you have a good recorder with an accurate editing counter, you can put several programs on a cassette keying up the program where required. If your tape counter is not accurate, you are better off using small cassettes (15 or 30 minutes) with a single program per side so that you only need start at the beginning of each side to have the program properly cued. The mumbling and fumbling that accompanies an attempt to find a certain set of pictures in a non-edited or poorly controlled tape will send the fellow at the other end looking for a cup of coffee or something stronger, particularly if he has heard this scene a hundred times before. Using tape, the station with a single camera can prepare innumerable programs while keeping the camera in position for live pickup during actual operations. If more than one video source is available – multiple cameras, keyboard, or flying spot scanner – the oppor-

tunities for creative programming are increased to the extent that all these sources can be utilized together in a coherent manner.

Many operators are also amateur photographers and maintain collections of 35mm slides that represent excellent potential program material. It is usually not feasible to set up the projector to work against a small screen and use the camera to pick up the picture. Either the projector or camera must usually be at an angle to the screen resulting in undesirable keystoning or foreshortening of parts of the picture. Even if the space is available to use a larger screen at a greater distance, the intensity of the projected image drops off. The solution is to use a rear projection system. A wooden frame between 1 and 2 feet square is used to support a piece of transluscent plastic. The projector is placed behind the screen with the camera set up on the other side. You can set up your slides in the proper order and use the slide changer mechanism to switch the slides between SSTV frames. This technique can be used with tape and a single camera or it can be used with a second camera while you are actually on the air. You should put the slides in backwards so they will have the proper orientation when viewed by the camera. If you have a keyboard, one of the most useful things you can do with it is to type "label frames" to be inserted between pictures to provide additional explanation of the visual material. WØLMD has designed a nifty titler circuit that will put a one line title in the actual picture frame. The letters are rather small, which makes them difficult to read under noisy conditions, but it does eliminate the need to interrupt the picture sequence.

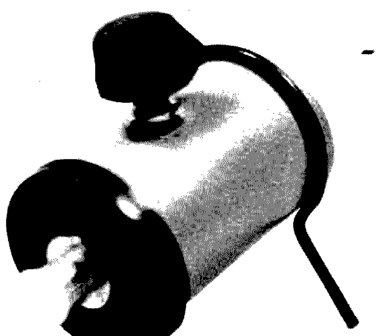
The flying spot scanner is also a useful tool for handling routine picture material either as slides or photographs. Several designs are presented in the *SSTV Handbook*. An FSS can handle CQ and ID slides, your cartoons, and any photos you might wish to transmit while leaving the camera free for live pickup.

The key to good programming is to have a smooth flow of material. Pictures should be changed during the frame transition to avoid erratic display and poor continuity. If your picture handling mode doesn't permit such rapid changes, consider putting that particular sequence on tape so the recorder can do the job of stopping one picture at the end of the frame and starting another right before the arrival of a vertical sync pulse. It takes some practice, but you can produce excellent tapes without having to cut and paste. Usually five frames of a given subject is the upper limit. Three frames is probably optimum. Longer programs should be reserved for excellent band conditions where with proper editing technique you could probably drop to two frames per subject, thus saving 8 seconds. Remember that the fellow at the other end will be looking at a 120 line picture, so choose your subjects accordingly. Obscure pictures, such as the backside of a sleeping cockroach, may be excellent for those engaging "guess what it is" games, but are unsatisfactory for general programming. The macro-focus freaks are fond of showing extreme closeups of things like ICs and postage stamps. While such manipulations work very well to demonstrate the equipment, they can be so-so in the interest department. I don't want to disparage stamps in general; it's just that most of us have seen the common garden varieties. If you have a collection of rare or beautiful stamps, by all means use them. A note here: If you want to use macro-focus to maximum advantage, use the camera in conjunction with a suitable fast scan monitor. Poorly focused pictures are to be avoided, and this problem is more prevalent when you start playing the macro-focus game.

A final note in regard to multiple camera sources. Why not use a common sync generator for all sources — camera, FSS, and keyboard — to eliminate wasted time in switching from one source to another? Many FSS units and most keyboards are home brew. Why not take the sync signals from your commercial camera and use these to control the other video sources? Broadcast stations stay in sync by using a common sync source for all video sources, and you can do the same. This sort of thing is optional, but it does add a nice touch. Those of you out there who like to tinker with the gear might consider the possibility.

The key to a high class operation is to choose interesting pictures and handle them with the maximum versatility and technical expertise that your equipment permits. Putting together a quality video operation is not only a challenge — it will mean that other operators will want to work you as often as possible and perhaps pick up some hints for their own stations. We are only just beginning to learn to use this new dimension and many new techniques will emerge as we work on the subject. At any stage, however, there is no more excuse for sloppy picture technique then there is for a sloppy fist or ham-handed phone operation. That kind of operating will always be with us, but let's see if it can stay in the background as SSTV forges ahead! ■

Don't Build This Project



--watch for my next...

James F. Reid W8LWS
4 Lawn Street
Ashley OH 43003

When I first got this brainstorm I thought I would earn a place in hamdom for building the world's smallest field strength meter. It may not be the smallest but it ought to win an award for something. Like many other projects that should have suffered an early death, this one started with a surplus of 35 mm film cans and the question "What if . . . ?" I might also add that this project started with a deficiency of thought. The meter is a tuning meter offered in many hobby catalogs and said to have "hundreds of uses." Residence in a 35 mm film can is not one of these uses. If you should be so foolish as to buy one of these meters you will probably find that it has an internal shunt resistor which will reduce its sensitivity for this use. This calls for a little creative destruction. Using a drill bit held in your hand, carefully drill a small hole near one end of the resistor. Then, using a small instrument (a crochet hook works well), carefully break the wire going to the resistor. The next step is probably to go out and buy another meter and try again – or give up right now. In case you were lucky and have finally modified the meter, seal the hole with model airplane glue. Cut a hole in the bottom of the film can to fit the meter (lots of luck). The film cans are made of plastic and are very soft. Start the opening with a carefully drilled hole and finish it off with a pen knife. Have plenty of film cans on hand before you start this, and run cold water over your head after every third try. If you have gotten this far you will realize that the only way to secure the meter in the can is to glue it there. Don't glue it yet! You still have a good deal of teeth gnashing before you're ready to tie things down.

The next step involves finding a small pot to fit in the can. Don't try to buy a new one. They're very expensive. Take the film can and the meter to the nearest surplus house and find one that will fit without pounding. Spend at least an hour deciding just where you are going to drill the hole for the pot. If you have committed a single sin within the past fifty years the hole will end up in the wrong place and you won't be able to get the meter and the pot in the can together. If by some miracle you have gotten this far, glue the meter and mount the pot.

You will notice that I have a vertical antenna on the back of the unit. This was, perhaps, the easiest part. Mount a female phono connector in the cap of the film can (it's easier if you take the cap off first). The antenna proper is a piece of coat hanger wire. Make a small right angle bend in the bottom of the wire and solder it to a male phono connector. As most do-it-yourselfers will tell you, you cannot solder to a steel wire, such as a coat hanger, without first invoking several deities. In my case I scraped the wire clean and then used acid core solder (horrors!). If you are fastidious you can wash the acid residue off with soap and water. Now beg, borrow or steal the teeny-weeniest parts you can find to complete the circuit. Carefully plan parts placement and the order of soldering so things will fit (how's that for a cop-out?). The only thing yet to construct is the wire feet, which were made out of the same coat hanger wire (see Fig. 1). Do not try to use the film can as a bending form for the circle of the wire feet. A flashlight battery works fine for this and is much sturdier than the film can.

This field strength meter sits on my desk and is noticed and commented on by practically no one. The only comment it ever got was from a female visitor who said she thought it was "cute."

Don't build this unit. Have a cold beer instead. Watch for my next project . . . an electronic whoopee cushion. ■

CW Regenerator/Processor

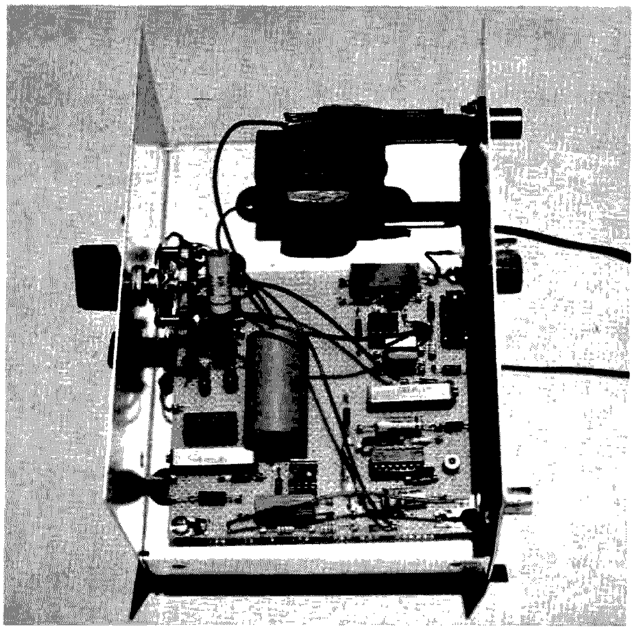
--also has TTL output for digital work

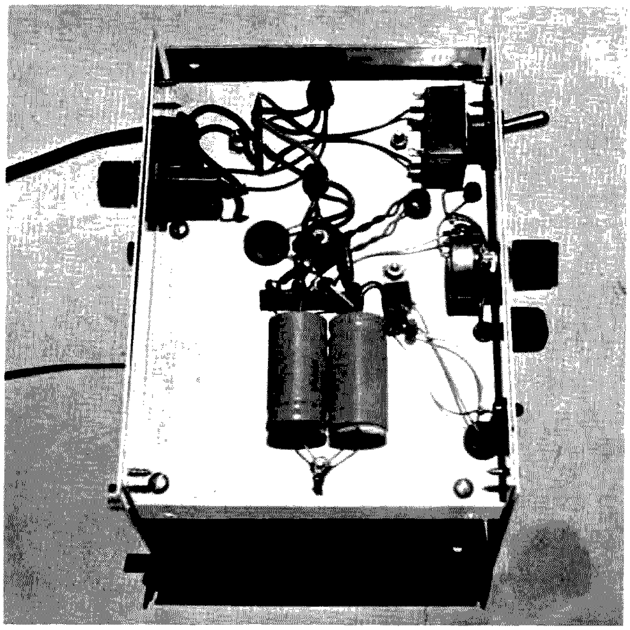
In an article in 1964, W6OI described a device called the "Paine Killer," which was designed to create a clean tone output from a relatively noisy CW signal from the audio output of a communications receiver.[1] The circuit utilized tubes and a relay, as did most such equipment of the day. Correspondence with the author indicated that he had every intention of redoing the Paine Killer using semiconductors; he may have done so, but it never came to my attention. My own plans to build a more modern version of W6OI's circuit were shelved in the "must get back to that some day" category.

A new application brought the whole idea back to life; a fellow ham wanted to build an automatic Morse code printer and needed a device to turn the noisy CW output of a receiver into TTL "ones" and "zeros." This had been done before in reference 2 by a circuit composed of five discrete transistors and 3 diodes, but the circuit didn't allow as much flexibility as I desired for experimentation. By using op amps and carefully separating functions, the IC circuit of Fig. 1 evolved.

Note, in Fig. 1, that in each of the three op amps we have the option of using voltage gain or not, as we choose. The first op amp, around which is built the "clipper," is operated at a gain of XII. When the *peak* audio input voltage exceeds about 0.45 volts, the output of U1A (pin 3) is at 7 volts peak. Since the inverting input of U1A (pin 1) is a virtual ground, the output voltage is effectively across the two inputs of U1 (pins 2 and 3). Note that only pins 2 and 3 of U2 are used, because this inexpensive op amp is being used as a matched pair of 7 volt back-to-back zener diodes. When the output of U1A attempts to exceed about 7 volts peak (either plus or minus), U2 goes into zener breakdown, lowering the gain of the amplifier built around U1A (by effectively putting a resistance in parallel with the 10k negative feedback resistor), so the clipper prevents the output of U1A from ever exceeding a (±) voltage of roughly 7 volts.

U1B is the heart of an





active bandpass filter with unity voltage gain, centered at 800 Hz, with a Q of 4. The design of this active filter is beyond the scope of this article, but can be found in reference 3. The Q being 4, of course, means that the filter is 800 Hz/4 or 200 Hz wide at the -3 dB points, that is, where the voltage response is down to 0.707 of its maximum value.

Around U3 is built an injection locked oscillator. The oscillator is basically a phase shift type, with the gain set at a value lower than that which will sustain oscillation. Since the non-inverting input (pin 13) is not involved in the oscillator feedback circuit (except for the requirement of being grounded via some finite impedance), it may be used as a convenient input port for external oscillator injection. The trick here is to increase the gain of the oscillator (adjust the 500k trimpot) with *no* audio injection, until oscillation is sustained; this oscillation should be near 800 Hz. Slight adjustment of any of the three 0.01 uF capacitors in the RC feedback network can be used to put the oscillator "right on." The oscillator gain can then be decreased until oscillation stops. An 800 Hz input signal can then be applied, and the injection level pot increased until oscillation starts again. The oscillation should only persist when an 800 Hz signal is present at the input.

The output of the injection locked oscillator is rectified by D1. The detector load time constant of this diode detector is approximately 5 milliseconds, which is a short enough time constant to allow reception of virtually all Morse code speeds. The dc level across part of the detector load is fed to U4, an LM311 voltage comparator. When the dc at pin 3 of U4 is more positive than that on pin 2, the output (pin 7) is "low." Since the voltage on pin 2 is set by the "voltage trip level" pot at (say) 1 volt, a zero dc voltage at pin 3 causes the LM311 output to go "high." A 10k resistor from pin 7 to pin 2 provides hysteresis and noise immunity to the comparator. The LM311 is capable of

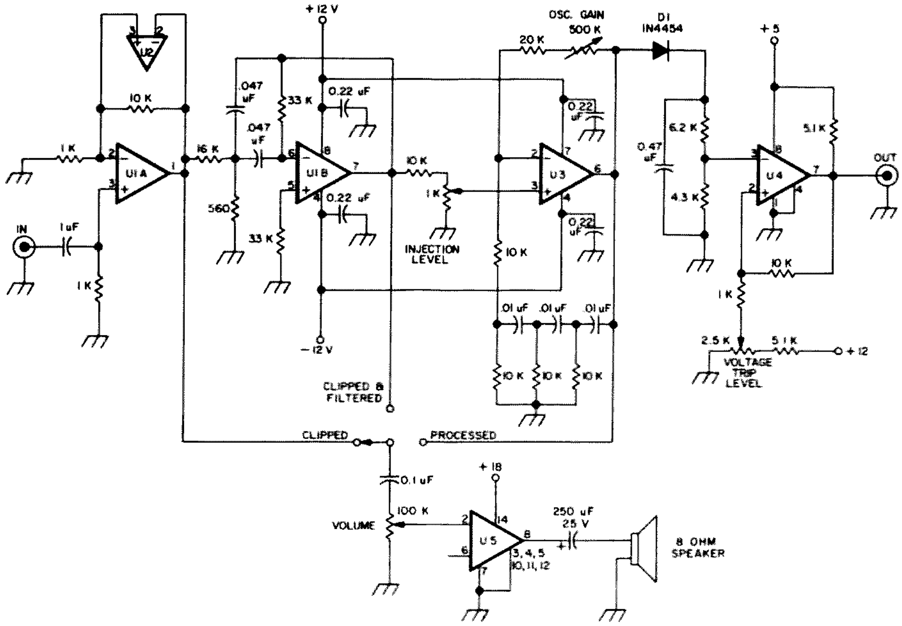


Fig. 1. D1 – 1N4454 or 1N914; U1 – National LM1458N or Motorola MC1458P; U2 – National LM709CN or Motorola HEP-C6103P; U3 – National LM741CN or Motorola HEP-C6052P; U4 – National LM311N or Motorola MLM311P1; U5 – National LM380N. All capacitors 50 V mylar except where indicated.

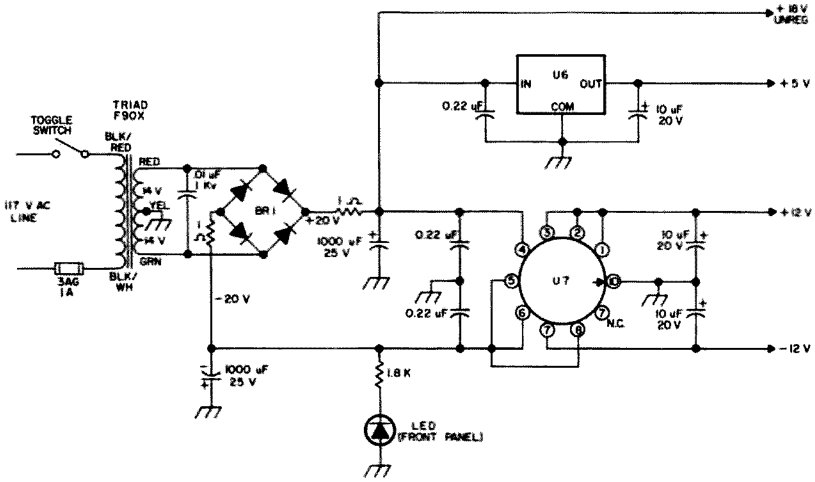

Fig. 2. U6 — National LM341-5 or Motorola MC7805 or HEP-C6110P; U7 — National LM326H (with T05 finned dissipator clip-on); BR1 — Motorola MDA920-3 or HEP-R0802 integrated bridge; LED — HP5082-4882 (Hewlett-Packard) or Motorola HEP-P2000.

driving TTL or DTL logic directly, if a digital system is to follow this unit. In such cases, the 5.1k load resistor may be omitted, since only current *sinking* is required with these logic ICs. If the digitized output is to be used to drive a pen recorder or a logic family like RTL or CMOS, the resistor is required.

U5 is a simple audio amplifier to allow the CW signal to drive a speaker directly. The National LM380N audio amplifier IC used here requires fewer peripheral components than most such ICs, operates on the unregulated + voltage at hand, and will drive an 8Ω speaker. The input to this audio amplifier is selectable from three points in the processor circuitry: following the clipper; following the clipper and bandpass filter; or following the clipper, bandpass filter, and injection locked oscillator. Thus, one may listen to as much or as little of the processing as he desires for each particular signal.

The power supply for the CW processor produces +18 volts unregulated, +12 volts regulated, +5 volts regulated and -12 volts regulated. The ±12 volts is provided by a special dual regulator IC by National: the LM326H. The +5 volt regulated is provided by one of the simple three terminal regulator ICs now widely available from several IC suppliers. The basic bridge rectifier is one of the integrated types from Motorola, for simplicity of construction. The power indicator is an LED type for long life, and operates at 10 mA from the -18 volt unregulated bus.

Since the CW processor has an input impedance of about 1000 Ohms, it can be driven by the output of nearly any receiver. It is a good idea to substitute a resistor of the nominal speaker impedance of the receiver, and then connect the processor across that resistor. For 4, 8, and 16Ω speakers, the additional 1000Ω will cause no appreciable mismatch. For a receiver with a 600Ω output impedance (like the R390A), a resistance of 1,500Ω would be used, so that the parallel combination comes out 600Ω .

In operation, when one is in the "clipped" position, the audio should sound pretty much as it would from the receiver by itself. The only difference should be that large impulsive noises are limited. The roar and grind of received background noise will be just as fatiguing as ever, however. In the "clipped and filtered" position, a CW signal (properly tuned to an 800 Hz beat) will take on a "soft" sound, and the grinding background noise will be considerably decreased. Finally, in the "processed" position, a CW signal (properly tuned to 800 Hz) will appear to "pop in and out" with slightly off-frequency heterodyne signals in the background at a considerably reduced level. If the oscillator gain control is set too close to the verge of self-oscillation, incoming noise will give an oscillator output that sounds much like a narrow crystal filter "ringing" with noise input. Too high an injection level will cause the background off-frequency signals to be objectionably high. The user must make the final compromise in setting these controls on a subjective basis. ■

Dependable Timer

-- for darkroom, repeater, etc.

This article describes a 60 Hz, line frequency based precision interval timer designed for use as a repeater timer, a photographic enlarger timer or general purpose timer where accurate, consistent time cycles are required. It is programmable by switches, is reliable, and requires no alignment or adjustment. It is accurate to ± 1/60th of a second.

While numerous articles have been published on simple interval timers, the majority of these timers have major drawbacks of one type or another. Timers using the 555 chip are subject to false triggering in a lot of cases. UJT timers such as those I described in my article "Simple Repeater Control Timers"[1] are temperature sensitive and will suffer a change in time interval as the temperature varies. This is especially annoying for repeater timers where the "three minute time" interval gets shorter and shorter as the temperature gets colder. In addition to these drawbacks, any timer which uses an RC network as the time determining network will suffer from problems when long time intervals are required, since the RC network becomes a high impedance network in this instance. Internal resistance in capacitors and high resistance flux shorts will

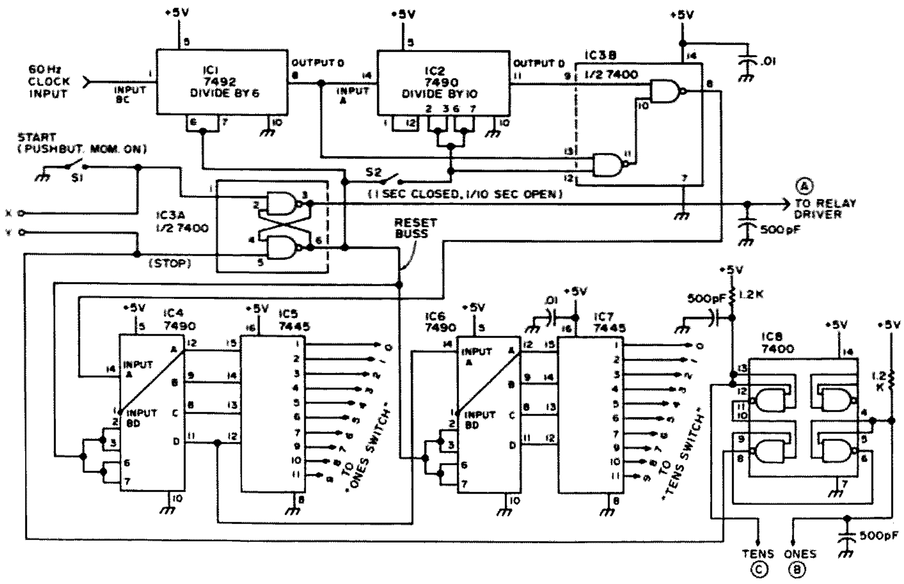

Fig. 1. Basic timer circuit.

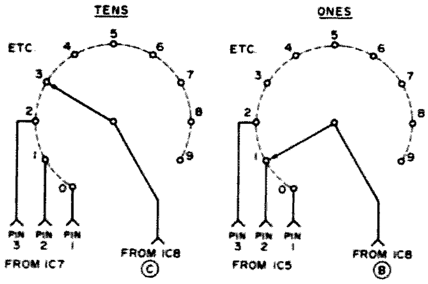

Fig. 2. Switch wiring.

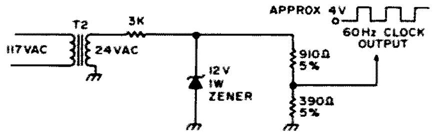

Fig. 3. 60 Hz clock.

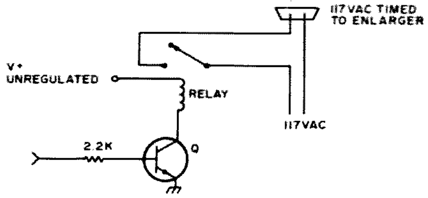

Fig. 4. Relay driver.

create havoc with these high impedance circuits. Furthermore, in cases such as an enlarger timer where it is necessary to select different time intervals, problems arise with selection of precision timing capacitors and resistors, or problems arise in that each timing range must be adjusted.

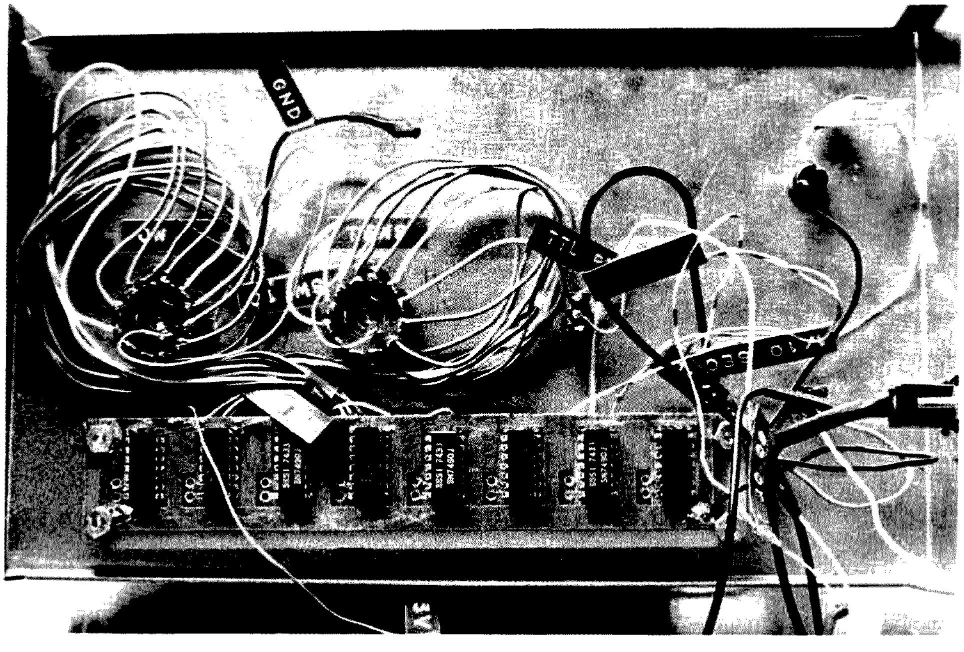
The primary disadvantage of the circuit described in this article is that it is time consuming to wire up 8 integrated circuits. The advantages, however, are numerous. This timer does not suffer from any of the problems previously mentioned. It will maintain its accuracy over a temperature range of 0°C to 70°C and will operate over a range of −55°C to +125°C merely by using the next better grade of IC (military grade). It takes no special skill to build and requires no special equipment to align. In spite of the fact that the basic circuit uses 8 ICs, the timer is not expensive to build. The cost of the 8 ICs is $7.50; the two good quality switches will run about $9.00. If you have a good junque box, there should be little additional expense.

Theory of Operation

This precision interval timer is not a complex device. It is merely a counter that counts pulses in either one second or 1/10 second intervals. A pair of switches is used to set the desired number of pulses to be counted. When the counter has counted the number of pulses set on the switches, the counter stops. The eight integrated circuits perform all functions needed to do the counting and to determine if the desired count is reached. The 60 Hz power line through a 24 V ac transformer and associated circuitry is used as the "clock," a source of pulses occurring at a 60 Hz rate (Fig. 3). The 60 Hz line frequency is accurate when obtained from commercial power lines. You can prove this to yourself by determining the amount of error in an electric synchronous clock over a month's time. The percentage of error is a small fraction of a percent. A dropping resistor, a zener diode and a voltage divider network are used to provide the required 4 volt pulses.

The 60 Hz pulses as they come from the clock are divided by 6 in IC1 (Fig. 1), producing a train of pulses occurring at 1/10 second intervals. For time intervals of short duration, these 1/10 second pulses are counted directly. A 7490 decade counter (IC2) is used to divide by 10 to give a stream of pulses occurring at 1 second intervals. This 7490 is switched in or out of the circuit by a series of gates in IC3, a 7400, depending on the setting of switch S2. If S2 is closed, counting will be by 1 second intervals. If S2 is open, counting will be by 1/10 second intervals.

The count is started by momentarily pressing the start button, S1. This "sets" the set-reset flip flop made from gates of IC3A, a 7400. At this point, all counters are reset and ready to count, and the relay is turned on. IC4, a 7490, is used to count by ones and deliver a BCD output to the 7445 decoder, IC5. The tens output of IC4 goes to the input of IC6, for a count by tens. IC7 decodes the BCD output from IC6. The outputs of the 7445 BCD to decimal decoder will sink current or go low when the proper count is reached. If



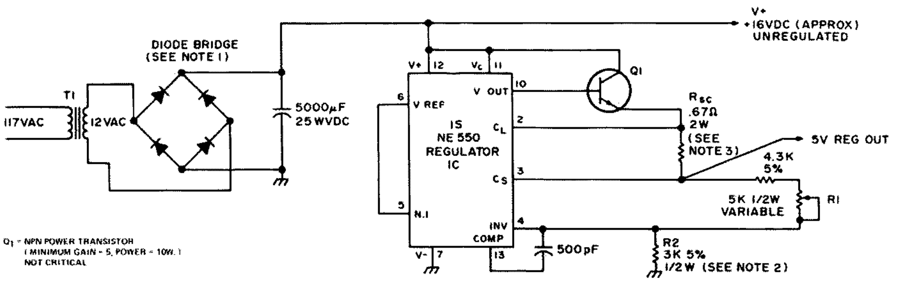


Fig. 5. Power supply. Notes: 1. Use either four 1A 60 piv diodes or an inexpensive diode bridge unit. 2. Using fixed instead of variable resistance, R1 should be 6.15k 1% and R2 should be 2.97k 1%. Using circuit shown, adjust for 5 V dc out. 3. Use four 2.7 Ohm ½ W resistors in parallel.

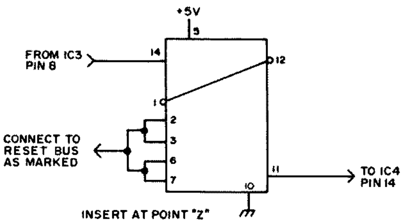

Fig. 6. Increasing time interval by factor of ten.

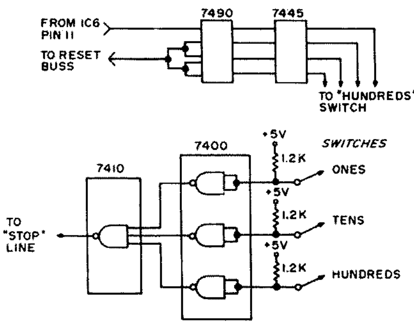

Fig. 7. Adding an extra power of ten with switch.

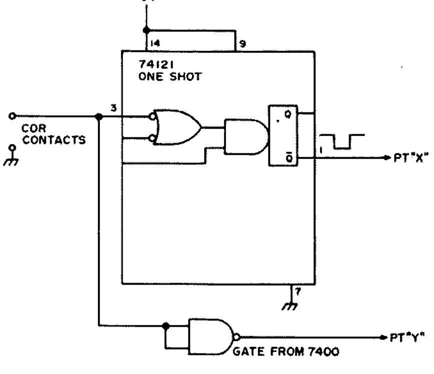

Fig. 8. Repeater timer interface.

you were to connect a low current lamp from +5 V to the "9" output on one of the 7445s, the lamp would light whenever a count of nine were reached. A series of gates is used to logically "AND" the switch selected outputs of the two decoders together to produce a stop pulse. When a stop pulse occurs, the set-reset flip flop in IC3A is reset, turning off the relay and turning off and resetting all counters.

The basic circuit as shown in Fig. 1 can be used in any environment where manual operation may be used. I used my timer as a high quality photographic enlarger timer. I merely plugged the enlarger into the 117 V circuit switched by the relay.

In any case where automatic start or automatic reset is required, the two connections X and Y should be used. Grounding point X will start the circuit and grounding point Y will reset the circuit before the timing interval is complete.

In order to use the circuit as a repeater timer, some minor additional circuitry is required. The circuit in Fig 8 is connected between the COR and points X and Y. The contacts of the relay are connected to the push to talk circuit. This simple circuit in Fig. 8 delivers a fast pulse to the start circuit when the COR contacts are closed. When the COR contacts are open the stop line is grounded, resetting the timer and turning the relay off. In operation, the switches are set to the "time-out" time desired. If the input signal remains on for too long, the time interval will be passed, a stop pulse will be generated and the relay will open up.

Note that the basic timer will time to 99 seconds, an interval which should be long enough for most applications including a repeater time-out timer. In the event that a longer time interval is required, the time interval may be lengthened by a factor of ten by inserting an additional 7490 integrated circuit into the circuit at point "Z" as shown in Fig. 6. If you wish to program this timer to three significant digits, rather than the two provided, then use the circuit in Fig. 7 instead, to add on one more switch and an additional power of ten. Note that only one additional 7490 may be added into the circuit using Figs. 6 or 7 without increasing the driving capability of the set-reset flip flop in IC3A.

The power supply is not a critical item. Feel free to use other circuits such as circuits using simple three terminal regulators. The eight ICs and the relay draw only 250 to 300 mA, so a fancy supply is not required. The circuit used is the one recommended by Signetics.[2]

Construction

Most builders have a tendency to cram too much into too small a space. For that reason I used a big 16x6x3½ inch minibox. If you use what is available from the junque box, you will probably need all the room available.

In my unit, I mounted the power supply, the relay, the relay driver and the components for the 60 Hz clock on the bottom of the chassis. I then used a piece of IC breadboard to mount the ICs on, and then mounted the PC board and the switches on

the top as shown in the photograph. You may make your own PC board or you may use a breadboard such as Vero #11821, available from Cramer for $7.35. If you wish you may also use Vector board or the equivalent.

When you are wiring the basic timer, you will want to consider the question of whether or not to use IC sockets. In my unit, I wired to the ICs directly with sockets. If you use surplus ICs or have a habit of blowing ICs, then use sockets. Remember that sockets are expensive and decrease the overall reliability of your unit. After completing all solder connections to the basic timer board, clean the board well with a toothbrush dipped in Tri-Clor-Ethylene or similar solvent. Clean the board until all traces of flux are gone. Flux that remains on the board may cause trouble initially. If it doesn't cause a problem right away, it will later on.

The only components which are critical are the switches. In this circuit, the switches handle very little current; thus there is not enough current being switched to keep the contacts clean. Because of this, it is important to use a good enclosed switch, or a switch made for IC work.

Conclusion

The timer described in this article has been used primarily as an enlarger timer in the darkroom. It has been successfully used for quite some time now. I have also tested it as a repeater timer for an experimental repeater which we worked on in the Hartford CT area. If you follow the hints in this article and make no wiring errors, it should work the first time. Good luck. ■

What's Up on 156 MHz?

--meet the marine world above 2m

The tide was out and the digital depth sounder buzzed an under-seven-feet warning in the cabin of the sloop *Freelance* as I cranked over and warmed up the diesel. Overhead, beside the companionway from the cockpit, the marine VHF FM rig chattered with Saturday morning pilots looking for signal reports.

I pushed in a button marked WX-2 on the transceiver and a continuous weather broadcast from Washington told me it would be a sunny September day with a peppy 12 nautical-miles-per-hour breeze. Depressing a red priority button on the Hy-Seas 55 marine rig brought its receiver back to channel 16, the emergency and general calling frequency monitored by all boats on the Bay. A quick cracking of the squelch verified the transceiver was receiving.

The depth sounder transponder, mounted in a hole through the hull under the bow of the single-masted sailboat, triggered a buzzer in the cabin as small waves got behind the seawall of the marina and rocked the boat. Whenever the transponder-to-bottom distance was less then seven feet, the in-cabin buzzer sounded.

Climbing the companionway stairs out of the cabin into the cockpit, I stationed myself behind the pilot wheel and slipped the diesel into reverse. The 31-foot fiberglass sloop chugged backwards out of slip 91. Clear of the moorings, I put the helm hard over and powered forward into open water of Annapolis harbor.

I glanced at my chart of the harbor waters and compared depths marked on that map with sounding depths being read out on a digital display in the cockpit. Motoring ahead to a point off the Severn River, I turned to starboard, facing the giant naval radio towers on Greenbury Point and the wide harbor mouth opening into Chesapeake Bay.

I leaned back down the companionway into the cabin and killed the diesel. Reaching up, I listened again to WX-2 on the marine radio for a prediction of wind speed and direction. The broadcast outlook appeared to compare correctly with indications of my red yarn wind telltales tied halfway up the mainmast shrouds. I punched the radio back to channel 16. The Yaesu FT-101-B HF transceiver was lashed to the navigating table in the cabin and my Wilson two meter handheld was strapped to the cabin bulkhead in arm's reach of the cockpit hatch.

With WN3AIQ maintaining the helm in the direction of the Bay, I went on deck to free the mainsail and run it up smartly. I winched the jib sheet to a moderate tension on the sail as we moved on the wind. The 5/8 wavelength VHF gain antenna 40 feet above on the masthead bent slightly toward the stern in the wind.

Parked in the Bay ahead were three huge freighters and a tanker, bound for Baltimore harbor. WN3AIQ turned up the volume on the marine rig and switched to commercial channels to see what the sailors from foreign lands were talking about (see Table 1 for uses made of different VHF FM marine radio channels).

A Greek freighter had sent a dozen crew members into Annapolis on shore leave. They were returning in a large orange dinghy. One was talking with the bridge of his ship, using a handie-talkie like the two meter HTs. We sailed straight out into the Bay toward Kent Island to inspect the Greek reboarding operation.

Circling the freighter, not an easy task under full sail, we headed south toward the Thomas Point Lighthouse. The tide was still going out so we moved down the Bay at what we calculated was a rapid seven knots. That's when eavesdropping on the marine channels got exciting.

The freighters were behind us, and we felt guilty about not monitoring channel 16 so we switched back to that frequency (see Table 2 for VHF FM marine radio channel numbers and their corresponding frequencies).

Almost immediately we heard, "Coast Guard Annapolis. Coast Guard Annapolis. This is *Sea Scraper.* The yacht *Sea Scraper.* Whiskey Zulu Yankee Four Nine Six Seven."

The quick response was, "The yacht calling. This is Annapolis Coast Guard."

"Coast Guard. We're aground on shoal near Thomas Point Light," *Sea Scraper* came back. WZY-4967 was his FCC-assigned VHF FM marine radio call letters.

"Can you go to channel 22?" the Coast Guard radio officer asked.

"Yes, we can. This is *Sea Scraper* going to channel 22," the yacht skipper replied before QSYing to the Coast Guard channel.

The Coast Guard radioman said on channel 16, "*Bay Chaser.* Coast Guard Auxiliary Vessel, *Bay Chaser.* This is Coast Guard Annapolis. Come in."

Three long-time Bay sailors, volunteers in the Auxiliary, had been cruising in their power boat in the Bay off South River. "Go ahead Annapolis. This is *Bay Chaser.*"

The Coast Guard asked if *Bay Chaser* would QSY to channel 22 to establish communications and help out in the *Sea Scraper* emergency. *Bay Chaser* left channel 16. WN3AIQ switched our 55-channel marine rig to channel 22 to listen in.

Rendezvousing on channel 22, the Coast Guard explained the problem to *Bay Chaser. Sea Scraper* had ven-

tured into shoal waters of about three-foot depth while attempting to get up close to photograph the picturesque old Thomas Point Lighthouse. *Sea Scraper* had plowed so far into soft mud on the bottom of the Bay she was stuck. The captain had tried to power backwards out of the hangup but couldn't budge the craft.

Bay Chaser established direct communications with *Sea Scraper* on channel 22 while the Coast Guard stood by. Coast Guard also kept one ear cocked toward channel 16 in case other emergencies came along.

"*Bay Chaser.* This is *Sea Scraper.* We may have damaged our hull. We're taking on some water in the engine room." The Auxiliary tried to speak soothingly to those listening aboard *Sea Scraper* while maneuvering in close enough to toss over a line.

WN3AIQ went forward, leaning out into the pulpit for a better view. We sailed silently nearer the action scene, without coming close enough to interfere. Mean-

Table 2. Channel Numbers and Frequencies in Use in the VHF FM Marine Radio Service.

while, we heard all that was going on via radio.

The Auxiliary, with a shallower draft, motored close enough to *Sea Scraper* to throw a line. We could see a woman and two children on the *Scraper*. The skipper grabbed the three-quarter-inch rope as it slapped his deck. He quickly tied off the line to a stern mooring cleat. The Auxiliary turned stern toward the *Scraper* and very slowly drew the line taut. Forward power in the *Bay Chaser* brought the *Scraper* out of the mud and back into six feet of water where she floated free.

"Stand by. We'll come aboard to check that water in your engine compartment," *Bay Chaser* radioed to *Scraper*. The Auxiliary pulled alongside *Scraper* and they rafted together with lines cleated fore and aft on each boat. One of the men on the Coast Guard Auxiliary went over the lifelines onto *Scraper's* deck, and then below to look at the possible leak. Pretty soon we heard this on channel 22:

"*Bay Chaser*. This is *Sea Scraper*. Joe, this is Fred. There must have been a rock outcropping in that bottom mud. He has a very small dent where the hull seems to have been crunched in by passing over something hard. There's a tiny crack letting water seep in."

The reply was, "OK, Fred. You stay on board. We'll take them in tow to South River Marina. They can get things checked out there."

With that, things got routine even though the channel 22 communications continued for some time. The Auxiliary untied from the *Scraper* and hooked a line from its stern to the bow of *Scraper*. *Bay Chaser* began pulling *Sea Scraper* toward the nearest boatyard where damage could be surveyed and repairs made. Radio contact was maintained with an

occasional transmission from Joe to Fred.

With WN3AIQ at the helm, I reached into the cabin and changed the radio back to WX-2. The special forecast for Chesapeake Bay was on. The day would continue to be pleasant; the evening would be fine. I checked WX-1 and found a different government station transmitting. It also was full quieting in the receiver. When sailing in the Annapolis area, I usually pay attention to WX-2, but WX-1 could be used. Their forecasts overlap. One or the other of the two weather frequencies hold loud and clear signals wherever you are on the Bay.

Back on channel 16, the communications were only those which could be justified as necessary. Occasionally, a skipper would pop up on frequency asking for a "radio check." Somebody would come back, "You're loud and clear." Both boats would identify by boat name and FCC call letters. Radio checks are in the gray area of legality and are not encouraged by the Coast Guard. But, sometimes a skipper gets edgy about who would be able to hear him in an emergency. He asks for a fast radio check and usually gets it.

Communications heard regularly on channel 16 might include pleasure boats hailing each other by boat name and radio call letters; pleasure boats calling the Coast Guard or being called by the Coast Guard; Coast Guard and marine police calling each other and their auxiliaries; freighters, tankers, fishing boats and other commercials hailing other ships, ports, marine police or the Coast Guard; or telephone operators paging both pleasure boats and commercial ships for which telephone calls are waiting.

All of this calling is done with radio operators careful to identify fully by boat name and call. As soon as communications are established, both parties leave channel 16 for a channel specifically authorized for their QSO. For instance, work boats might go off onto channel 67. Fishing vessels might QSY to channel 88A. A pleasure boater might leave channel 16 for channel 9 after getting in contact with his marina or yacht club. The telephone operators ask you to call them back on specific channels between 24-28 and 84-87.

By the way, as with all radio communications except broadcasting and ham transmissions, you can listen all you want but you cannot repeat legally what you heard. And you can not use information heard on the air for your own personal gain. If you hear a boat being paged on channel 16 by your local marine telephone operator and you QSY to a channel to hear the conversation between boat and shore, don't tell anybody what you heard. And don't make any use of the information contained in the telephone call. The *Sea Scraper* emergency reported here is composed of parts of many I have heard on the Bay.

With the excitement over for the moment after the rescue of *Sea Scraper*, we left the marine rig monitoring 16. Unstrapping the Wilson, we keyed up the Jessup MD .16/.76 repeater from atop 100 feet of water in the middle of the Bay. A quick QRZed on .52/.52 raised Charlie WA3RPU, piloting his giant motor-freighter near the Sandy Point Light en route to Norfolk. But using HF and VHF ham gear maritime mobile is a story for another time. Next time you're boating on the Chesapeake, call *Freelance* WYN-2260 on channel 16. We could QSY to .52/.52 for a quick QSO. ■

Oops! There Goes the Power

-- keeping digital clocks going anyway

Digital clocks have long held a fascination for me, and judging from the number of articles in electronics publications, they also hold a high attraction for many other people. I've gone through all the stages from a complete discrete (?) integrated circuit clock with minitron readouts to the latest MOS clock chips with LED readouts. As a result, I have learned a few lessons which should be of interest to other "clock fanatics."

One of the most frustrating problems with any ac powered digital clock is its volatile memory – that is, when the power fails for even an instant, the memory of the displayed time is destroyed, and when power is restored, the clock will not display the correct time. With some MOS chips, the clock will reset to 12:00:00 or 00:00:00, while with others any time may be displayed, even impossible times such as 28:42:00. Several methods of preventing this situation are available: (1) Use a crystal oscillator timebase and battery power; (2) Use the ac line for timebase and primary power with battery power to prevent memory dump when the ac power fails; and (3) Use the ac line with capacitor backup as a power source when the ac power fails for momentary retention of clock memory. Obviously, (1) is the most desirable setup since the clock can then be used in a car, boat or any portable requirement. It is the least desirable from the standpoint of cost and complexity. A partial diagram of such an arrangement using the 53XX series of clock chips is shown in Fig. 1. (2) is a relatively uncomplicated arrangement which prevents loss of memory and, depending upon the length of time that the ac power is off, will provide good service. The clock is not triggered during the time the power is off and will show a loss of time when the power returns. Also, during the power off time, the display will not be illuminated. Since the displays draw the majority of power, only the clock chip is battery powered during the ac power failure. Fig. 2 shows a partial diagram of the battery powered arrangement. Either dry batteries or rechargeable batteries can be used and are depicted in Figs. 2(a) and 2(b) respectively. In effect, the battery "floats" across the rectified ac power source and is switched on by diode D1 upon failure of the ac power. Note also the use of diode D2 which isolates the display power from the battery. If this diode is not installed, the battery will be quickly discharged by the display current drain. In Fig. 2(b), a method is shown which will keep the rechargeable nicad battery on trickle-charge from the ac power source. Solution (3) is one of the best solutions to the problem that I've found. Most power failures are of a momentary nature (less than 2 – 3 seconds) in areas where I've lived, and these are the most frustrating for clock owners. In some cases, the failure is not even noticed, yet the clock's memory is destroyed and the clock must be reset. To overcome this problem, I now use the circuit in Fig. 3. Notice that the only addition to the standard clock circuit is one diode. This diode acts as a switch. During normal ac operation, the switch is

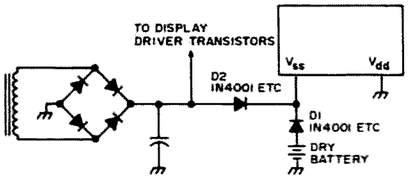

Fig. 2(a). Dry battery memory backup.

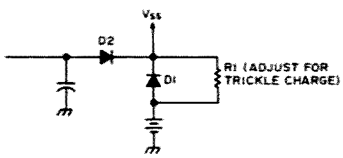

Fig. 2(b). Trickle charger battery backup.

closed and power flows from the bridge rectifier to the display directly, and through the diode to the filter capacitor and the clock chip. Upon power failure, the diode switch is reverse biased by voltage stored in the filter capacitor and the display is not illuminated. However, power from the capacitor flows continuously into the clock chip for several seconds and the memory is retained. Since the MOS chips draw only about 8 mA and will operate down to about 7 to 8 volts, the capacitor can supply power for several seconds. By using a 14 volt supply and a 3,000 uF capacitor, approximately 5 seconds will pass before memory destruction occurs. This is by far the least complex and least expensive method of improving the reliability of digital clocks.

One other tidbit of information concerns the 50252 clock chip sold by Radio Shack and other dealers. This chip requires that you depress both the tens-of-minutes and hours time set switches to advance the minutes display. This is somewhat cumbersome and more times than not I advanced the tens-of-minutes digit or the hours digit because the switches were not depressed simultaneously. The solution involves a third switch and two diodes (1N4148s or similar) and is shown in Fig. 4. The added switch now advances only the minutes display with no worry of accidentally advancing any of the other displays. This particular clock chip has several desirable features such as 24 hour alarm, 10 minute snooze alarm and a built-in tone generator for the alarm. However, it does have one disadvantage which is not immediately obvious — it cannot be operated in the 24 hour mode on 60 Hz power. This feature is a matter of individual preference and was somewhat of a disappointment to me. I'm unable to figure out why the chip functions like this since the alarm feature always operates in the 24 hour mode regardless of the input power line frequency (50 or 60 Hz); however, the display will only operate in the 24 hour mode when the input is 50 Hz.

Since many of the MOS clock chips are now in the $5 range, uses other than just a timekeeper should be explored: frequency division for counters or synthesizers, portable timers for sporting events, etc. It appears there are many possibilities and if you have some ideas, I'd like to hear from you. ■

TT Pad for the Wilson HT

-- and a belt clip mod, too

In November, I attended the ARRL New England Division Convention in Hartford and took along my Wilson 1402SM two meter FM hand-held transceiver. I wore it on my belt and with its miniature touchtone pad, it attracted the attention of many hams.

A number of hams even stopped and asked questions about the rig and some wanted to have a closer look. When I gave them a closer look, they were further impressed by the addition of a belt clip on the back of the transceiver.

There was a lot of interest in my modified Wilson; at one point, there were a half dozen hams surrounding me on the convention floor asking questions (I felt I was conducting an unscheduled technical forum!). And, there are a lot of Wilson owners, so I thought I'd write a how-to article for these hams and all hand-held transceiver owners, since the modifications I made on my transceiver are applicable to most of the other hand-held rigs available today.

After I purchased my Wilson, there were two things I wanted to add – a touchtone encoder and some kind of clip that would permit me to attach and detach the Wilson from my belt or pocket quickly. The Wilson does have an accessory leather case with a belt notch permitting it to be attached to your belt; the problem with this is you must unbuckle and remove your belt each time you wish to use the transceiver and this does not promote swift communications. Also, I like to throw my Wilson in its nicad charger whenever I'm not using it . . . but this isn't easy to do because you must remove the leather case before the rig will fit in the charger. For these reasons, I filed my leather case in the bottom of a desk drawer and looked for a better way.

I noticed that many Motorola HTs have just the kind of clip that I was looking for, and after doing a little inquiring, I found that the clips were available separately from Motorola.[1] I purchased one to try out on my Wilson. To attach the clip to the rig, you have to take the transceiver's plastic case apart. First, slide out the battery pack and remove the four screws on the back and bottom of the unit. The front of the case will then snap off, hanging by a couple of wires. Now, remove the five screws holding the PC board to the back of the case; these screws are located at the corners and center of the board and when they are removed, the back of the case snaps off completely from the rest of the unit.

The belt clip has two holes in it for mounting and two 2-56 x ¼" round head machine screws will do the job. Using the clip, you can make a template and be able to mark the spots on the case where you will have to drill. Be sure these spots are centered on the upper quarter of the case.

Use a hand drill and not too much pressure or you might crack the plastic case. After the holes have been

made, take a small screwdriver and jam it into the belt clip's spring in order to keep the spring open. This permits the clip to be mounted parallel to the back of the case. Now, mount the clip with the two screws; nuts and lockwashers are unnecessary as the clip itself will lock the screws in place. If the mounting is done properly, the heads of the screws won't be in contact with the PC board; however, if it makes you feel more secure, cover the screws with a piece of electrical tape.

Now you can reassemble the case and the job is complete. If you wish, you can spray a couple of coats of paint on the clip to match the color of your rig ... "wrought iron black" did the trick with the Wilson.

When I was looking for a touchtone encoder for my Wilson, I heard about the new Motorola MC14410 IC for touchtone application, and at the same time, Data Signal, Inc.[2] began advertising their touchtone encoder kits which implemented the Motorola chip. For only $24.50 you get the chip, PC board, 1 MHz crystal, the keyboard of your choice and all of the other necessary components. I ordered the small 12-digit keyboard because the larger board mounted on the Wilson would not fit in the nicad charger.

After receiving the "kit," a few wires remained to be soldered and the keyboard had to be mounted on the front of the Wilson. I made a template by tracing the keyboard's mounting posts and pins on paper. After removing the battery pack and front of the case, using the template, I marked the spots to be drilled. The template should be positioned as close as possible to the speaker, so that when the keyboard is mounted, it will be clear of the nicad charger.

After drilling and filing the necessary holes – four for the corner mounting posts and two for the two rows of pins – bring the wires from the PC board through the holes making sure that the wires to be soldered to the right row of pins are brought through the right hole and the wires to be soldered to the left row are brought through the left hole. Solder the wires close to the plastic base of the proper pins and clip off the excess pins; this will provide sufficient clearance for the nicad battery pack.

Carefully mount the keyboard onto the front of the case and use a soldering iron to melt the mounting posts to the inside of the case. The keyboard will be stably mounted.

Now solder the ground wire to the negative battery terminal and the plus 12 volt wire to the VR3 volume/on-off control. If you are using a 12-digit keyboard, there will be one wire left that is used for the 16-digit board; this wire can simply be cut off.

After the wiring is completed, wrap the PC board and crystal with electrical tape and fit it snugly between the crystal switch and front of the case. The board will remain in this position; however, you may want to secure it with additional tape.

Any excess wire should be pulled up and taped near the speaker so that the wires running parallel to the battery pack will lie flat on the case. In addition, this parallel-running wire should be taped down onto the case. Now, reassemble the case, slide in the battery pack and you'll be on the air with your belt-clipped TT'd HT. ■

[1] Part Number 42-82839 J01 available from Motorola, 85 Harristown Rd., Glen Rock NJ 07452, (201) 447-4000 ... $4.50 will cover the cost of the clip and shipping.

I/O EDITORIAL

COMPUTER CONVENTION

The MITS World Altair Computer Convention in Albuquerque came off very well with some 500 plus computer hobbyists attending. The convention was run in the Airport Marina hotel, just around the corner from the new MITS plant.

Since only Altair computers were being shown, there were not a lot of exhibits ... but those which were there were of interest. Probably the most exciting was a ham station (WA8VNP) set up and operating in the RTTY contest (which was coincidentally on that weekend). The whole works was being displayed on a CRT with one area for the received copy, one for the copy being typed to be sent, another for checking for duplicates, and a fourth for logging. A built-in clock added the time to each exchange.

All the operator had to do was type in the call of the station to be worked and the report ... the computer then checked to see if that station had yet been worked on this band ... if so, it typed out "Dup." If not, it would go ahead with the contact when given the word to start.

Another system was showing a biorhythm display. It would ask your birthday, how many days you would like shown, and starting with what date ... from there on it would plot your emotional, intellectual and physical curves, showing you why things went so wrong or perhaps what you might expect next week.

Cromemco's TV dazzler was one of those gee-I've-gotta-have things. I'm not sure what it can do, but it was impressive in its ability to show colors on a big color TV set. I suspect that someone into art could work up programs which would be real knockouts.

In view of some past hostility to firms making Altair-compatible boards, it was surprising and comforting to see one competitor there with a display of their boards.

The day and a half of the convenion was all too little for all the alking and seeing to be done.

And hams? A substantial number of hose who came had HTs sticking out f a pocket!

I finally found out what MITS stands for ... seems they got started in 1969 making telemetry kits ... it is icro Instrument and Telemetry ystems. In 1970 they got into calcuators and by 1974 had taken a errible beating as calculator prices plummeted. They were just about to give up when they came up with the Altair 8800 computer – and the rest is history.

MY BIG SPEECH

Since the other editors in the field had been asked to give a talk, I came prepared, too ... hoping that perhaps I had just been overlooked. It turned out that I apparently was not in the same league as the others, so I still have my notes.

The basic thrust of my proposed talk had to do with the almost unlimited opportunity that microcomputers afford. I doubt that there has ever been a time in the past when it was possible to see so clearly the opening of a whole new field ... a multi-billion dollar field. Flying pioneers knew they had something, but they had no hint of the magnitude. You have to be fairly old now to remember the almost universal reservations which greeted television in its early years. My folks were really upset when I went out in 1948 and spent $250 for a ten inch black and white set ... a waste of money ... we'll never watch it ... etc. We watched it ... including wrestling, westerns, everything.

The hobby computing field is fantastic. It isn't very big as yet ... in fact, it may never be very large ... but it is going to have a profound effect on the history of the world. The computer hobbyist is going to pay for the technical development needed to build small computer systems which are needed by small businesses, schools and homes.

You can today buy a computer system for about $5000 that would only a couple years ago (or less) cost you around $50,000 ... and this is only the very beginning. Let's look ahead a little ... how long will it be before we have the $299 smart terminal? It will have a black and white TV monitor (they run about $75 new these days) ... a 16K RAM memory for programs and storage ($20?) ... a ROM with text editing and word processing programs ... a printed circuit board keyboard like the ones now used for tone pads on HTs ($5?) ... a video display chip ($5) ... keyboard/ASCII chip ($3) ... etc.

What office desk will be able to be without a desktop terminal? It will be used to type all letters, will work fine for form letters, will act as a file cabinet or card file, calculator, Teletype via phone lines, handle all the bookkeeping and accounting, send invoices, print out labels, inventory, etc. Each office will probably need some hard copy device ... either a line printer or a photo copier to read from the tube. They will need some data bank ... tape, disk ... or something not yet invented ... perhaps like a video disk system.

One of the tech sessions at the MITS computer convention. Over 500 computer hobbvists came to Albuquerque for the do.

Every worker in an office will need a terminal ... every retail store will need one to keep track of sales, inventory, costs, etc. Will the computer terminal be as common on school desks of the future as the inkwell was when I went to school?

And how about the home? The terminal here could be used for an almost infinite number of applications ... security ... heating ... grass watering ... message center ... letters ... banking ... ordering from local super market for delivery by electric cart ... ordering from Sears, etc. ... any school course of instruction ... games ... and etc^n.

I see these markets as inevitable, and I believe that they will evolve from the present computer hobby systems ... with hobbyists both paying the freight for this development and participating in it. I also see this as a very good way for things to go.

Let's suppose that IBM or DEC had the vision to come out with a $299 computer, complete with CRT, keyboard, some ROM programs, RAM memory and the ability to interface with larger memory, other terminals, line printers, etc. It just might happen that their present system of selling would stick ... factory to customer via local factory reps and service centers. That would deal us out of the big ball of wax.

But the present system, which is developing with small manufacturers, local computer stores for sales, programming and service, affords a much more widely based market ... one that can accommodate many manufacturers and still keep prices down. The pricing schedule of the big computer firms is a tough bone, with many items being marked up 100% when sold by other than the manufacturer. A $1500 printer then sells for $3000!

Computer stores will be much like hi-fi stores, carrying equipment of many manufacturers and mating compatible gear. The old OEM price schedule will hold for dealers and the markups will be more like 35% than 100%. Maybe even less.

Continued

Your guess is as good as mine as to how many terminals will be sold to handle some 44 million school children . . . 80 million homes . . . and perhaps 60 million workers who might need one. I'd say that it will be a large market . . . maybe 25 to 50 million terminals per year . . . plus peripherals such as memory, printers, etc. That would certainly come to 10 to 30 billion per year in sales. Not bad for a market that doesn't even exist today!

As long as the big computer firms don't notice this market, it will be wide open to the newcomer . . . and that means the computer hobbyist has a big advantage. Few others have the range of experience needed to get this new industry started . . . the hardware and software background combined. In five years the big manufacturers in the micro field may well be the small firms which are springing up today to provide hobbyists with equipment.

It is possible right now to develop a computer product and get into production with it for very little . . . and do well. Never has there been such an opportunity in the computer field for small businesses to start and grow. An investment of a couple of thousand dollars today could well launch a company worth over a million dollars in just a year or two.

Well, that's the message I thought the computer hobbyists and computer store owners might be interested to hear. Time will prove whether I am overly optimistic or not. My past predictions have come off well, so maybe I'll hit again.

PROGRAMS FOR SALE?

Newcomers to the computer field are sometimes surprised, once they have their system up and running, to find that all they have is machinery and the darned thing just sits there . . . not *doing* anything. Not that everyone hasn't heard of software and programs — it's just that many neophytes don't understand the tremendous importance of such.

Old hands are culpable in this, too, for they are generally familiar with a commercial or school system which came with software and, shucks, you can get all sorts of programs from the users groups . . . from libraries . . . no strain. Oh yeah?

Foreseeing this problem last year, I organized the Kansas City meeting of the microprocessor industry to form a standard cassette medium for program interchange. The meeting was difficult to get going . . . I had to get the site set up for it . . . send out letters to all involved . . . write it up in *Byte* . . . and then make an awful lot of phone calls to follow it up. The meeting, for which *Byte* has been given credit, was my idea and my doing . . . and the people who had taken over *Byte* were furious that I had set up the conference . . . they didn't want to be bothered.

So much for that.

So now we have a medium which can be used for entering programs into small computer systems. One thing which I think will help hobby computers and small business computer systems grow more than anything else will be a low cost plentiful supply of programs. I hope to provide same.

Here is the deal. I will buy programs from programmers and pay a good royalty on them. I will duplicate these and have them on sale in all of the computer stores around the country . . . and possibly in some of the more forward looking electronics distributors. I will have them carefully checked in my own lab to make sure that they work as advertised and that duplicates are perfect. We already have excellent tape duplicating equipment which we use for making the Morse code and radio theory cassettes we are presently selling . . . over 2500 a month.

Don Alexander WA8VNP and his RTTY station — winner of the grand prize in the MITS Altair demonstration contest. The home-built system consisted of an Altair 8800 with 8K of memory, an ASCII keyboard, a video display, Baudot teletype and Heath transmitter and receiver. Don also wrote the assembler and editor for the system, as well as the software to run the amateur station. The Altair did the Baudot/ASCII translation, cross-checked calls for duplication, and automatically sent the time and message number along with any text generated by the keyboard. After each contact, a logging entry was made on a model 26 teletypewriter. Don won a complete floppy disk system as the prize.

If you are a programmer and have a good program available, please let me know. I need to know what it can do, what system it is for, and how much memory it takes. We will be able to check out programs on the Altair 8800 . . . have been promised a Sphere system . . . and hope to eventually have all other popular systems set up and running so we can check the programs.

What kind of programs can sell? Just about anything. I would expect we might have a cassette with five games on it which would go for $2.95. A real fine Star Trek program might go for $4.95. A payroll program for small businesses could go for perhaps $19.95. We would want to keep the prices down to where it would not be worthwhile to bootleg them or even make copies for friends . . . thus getting out from under the problem MITS has had with their BASIC, which apparently has been copied quite a bit.

Programmers would benefit substantially under this plan, since they would make 10% of the gross sales. Thus a $12 program would wholesale to computer stores for about $8 and the programmer would make an 80¢ royalty. This would mean $8,000 royalty for every 10,000 of the programs sold . . . and with several hundred thousand customers out there, if only 10% of them bought a given program this would mean a very nice return for the effort of writing and documenting the program.

These programs would be a bonanza for the stores . . . it would give them the ammunition they need to sell systems . . . not to mention that they might eventually be a good profit item in themselves as businesses and hobbyists come into the store to find out what new programs are available every week or so.

It is going to take this idea a while to get into motion. First we will have to get our own computer systems up and working . . . our experience has shown this not to be a minor undertaking. We have two computer techs and programmers on our staff right now and are looking for more. Then we will have to run thorough tests on cassettes to see which work best . . . using a computer to check each tape as it is made, comparing it, bit for bit, against the original.

Programmers . . . it's time to get working on your programs. Be sure to document them well . . . be sure you are not drawing on others' work . . . all our programs will be copyright . . . please put in some extra steps which are not needed, as a key to copyright infringement prosecution. We will need games . . . chess, backgammon, Star Trek, and so forth . . . business programs such as inventory, general ledger, accounts payable, accounts receivable, mailing list, and so forth. We will have to have a statement from you that your work is original.

Hopefully this system will provide the money to encourage programmers to work overtime to provide the software we need to sell small computer systems. By bringing a system to this presently chaotic aspect of computers, perhaps we can help the field to grow more rapidly.

Here is John Craig, the editor of the I/O section of 73. *John lives in Lompoc, California, where he is busy setting up some of the more popular microprocessor systems for evaluation.*

ATTENTION, CLUBS!

One of the big problems for many club meetings is getting interesting material . . . so I've been watching out for interviews which I might get on tape which could be of interest to clubs.

The first tape I have available is an interview with Ed Roberts, the president of MITS . . . the first manufacturer of microprocessor kits to hit the jackpot. His Altair 8800 computer kit came out about a year and a half ago, just as MITS was in serious shape as a result of the plummeting prices in the calculator market. Their first year's sales of computers was about ten times what they estimated, and they are just now beginning to get caught up with events.

Ed's story is an interesting one, and it will give you a lot of insight into the manufacturer's side of things . . . it will also familiarize you a lot with the computer scene . . . what microcomputers are being used for and where the market seems to be going. Hear about some exciting technical developments which are coming.

The tape is on cassette only and is one hour long. It was made with top notch professional equipment, so the sound will be as good as your cassette player. Order Cassette Interview I . . . and never mind the usual prices for such tapes, normally around $12.95 . . . *73* is in the magazine business, not in the tape business, so your cost is only $3.95 postpaid.

This tape may also be of interest to repeater groups which run club bulletins and news of interest to members over the repeater.

Power Supply Testing

-- to save your digital circuits

Ralph Tenny
PO Box 545
Richardson TX 75080

The home computer hobbyist is frequently lured by advertisements for surplus power supplies and power supply kits of all kinds. These offerings range from excellent buys of surplus name-brand units, to units, both kit and assembled, of unknown pedigree.

Performance specifications of these units sometimes are not fully stated in the advertising, but name-brand units can sometimes be researched in the manufacturer's literature. The "orphans" can literally be almost anything, and some surplus dealers are, at best, only brokers. These dealers may not have the necessary equipment, time or interest to characterize surplus units they buy. Power supply kits may or may not have been carefully designed.

Where does this leave the computer hobbyist? Except for his purchase of name-brand units, he can be on a very shaky limb. Problems which might hit him can be one of three: complete failure, regulation failure, or the units may generate random and potentially harmful transients.

A complete failure is a nuisance at best and could be a costly disaster. The CPU can simply be shut down when the power supply quits, and few uP systems have power-fail programming to save the run. Here are two possible disaster scenarios: A series pass transistor shorts and dumps raw dc into the uP systems, destroying all or most of the parts. Or, some critical power supply part fails, starts a fire, and destroys the house. Although the latter is unlikely, even commercial computers have been known to catch fire.

Regulation failures can be explained as a condition where the regulator circuitry ceases to operate in its linear region, usually because the input voltage to the series pass element gets too low. Another problem can be thermal runaway if the unit has not been properly designed for continuous operation. A properly designed supply will protect itself and the load in case of shorts on the output.

The symptoms of regulator failure are low and unsteady output voltage, usually with high ripple feedthrough. The effect on the CPU depends upon which logic family is used in the system. CMOS will be least affected, followed by MOS uP and support chips, and then TTL will be most affected. This non-linear regulator will also have higher than normal output impedance, which leads to coupling between fast logic elements. The uP system may drop an occasional bit, or become completely confused and lock up. Either way, the CPU is out of business.

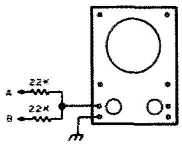

Fig. 1.

Transients on the output come from the power line or are generated by an improperly designed power supply. Power line transients can usually be stopped by transient limiters on the power supply input, and

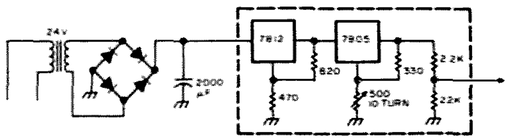

Fig. 2.

output spikes generated by the power supply can be caught by crowbar circuitry. But, if the crowbar has to fire, the CPU will still be shut down in mid-stride. Properly designed power supplies will not generate spikes under any condition of turn-on or turn-off. Of course, we all know that big spikes will kill any IC; we need to remember that small ones may cause improper system startup. Few home brew systems are designed and programmed for standby operation, but main supply shut-down spikes could also bollix the remaining active circuits.

Fortunately, power supplies can be screened for most of these possible defects, using relatively simple equipment. When investments of the magnitude required to own a home processor are concerned, it pays to screen all power supplies not furnished by the system manufacturer. If any home system manufacturer should be guilty of supplying inadequate power supplies, it is likely that the "computer grapevine" will get the word out promptly unless he corrects the problem. For those hobbyists who design their own units, remember that solid state power design is tricky, and even experienced designers test their prototypes thoroughly.

A modest amount of test equipment and two easily built gizmos will enable very extensive qualitative power supply testing accurate enough to assure the hobbyist of adequate and reliable performance from power supplies he uses. *Quantitative* testing, required mostly to prove one's prowess at power supply design, will require more and higher quality equipment. The test equipment needed is the following: a 20k Ohms/volt VOM, a variable autotransformer, a pulse generator, a very stable power supply, and an oscilloscope. The scope should be dual-trace with triggered, calibrated sweep, 5 MHz bandwidth and 10 millivolts sensitivity. The sensitivity and bandwidth are essential, and the triggered sweep will reduce frustrations during much of the testing. However, if a single-trace scope with the other qualifications is available, it is possible to get by with a couple of smart-aleck tricks. Fig. 1 shows how two signals can be mixed on one trace. This trick is good only on two low impedance sources, and it reduces the effective voltage of each signal to half its real value. In place of the calibrated sweep, let signal "A" be the signal to be timed, and signal "B" can be narrow pulses from a pulse generator with 1 kHz output. The resulting display will show 1 millisecond "tick" marks superimposed on signal "A." If the scope has a Z axis modulation input, the pulses can be used to intensify the trace as a time marker.

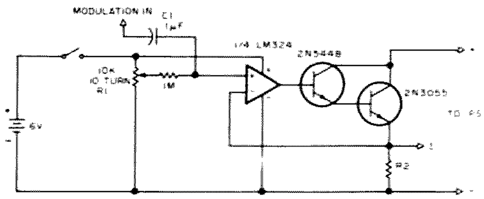

Fig. 3.

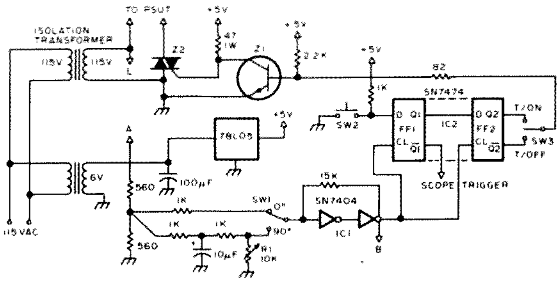

Fig. 4.

The power supply will be used as a comparison standard to check regulation and stability of the power supply under test (PSUT), so it must be much more stable than the PSUT. If there is the slightest doubt, Fig. 2 shows a circuit suitable for a reference supply. All parts inside the dashed line should be built inside a thermally insulated box and the supply should be allowed to run continuously for best stability. The output will vary from below 5 volts to around 18 volts, which should cover all supplies of interest to the computer hobbyist. The other equipment is very common, and the applications discussed below will explain their use.

The first special gizmo is a dynamic load — a circuit which simulates the type of load fast logic places on a

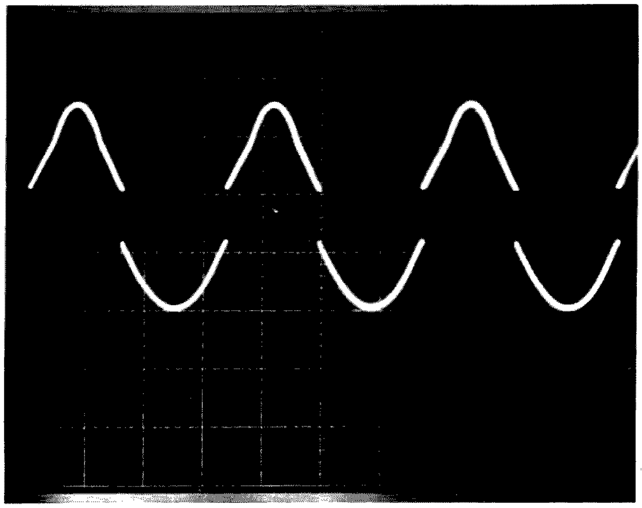

Fig. 5a. Mixed waveforms from circuit of Fig. 4 showing trigger at zero crossing of line voltage.

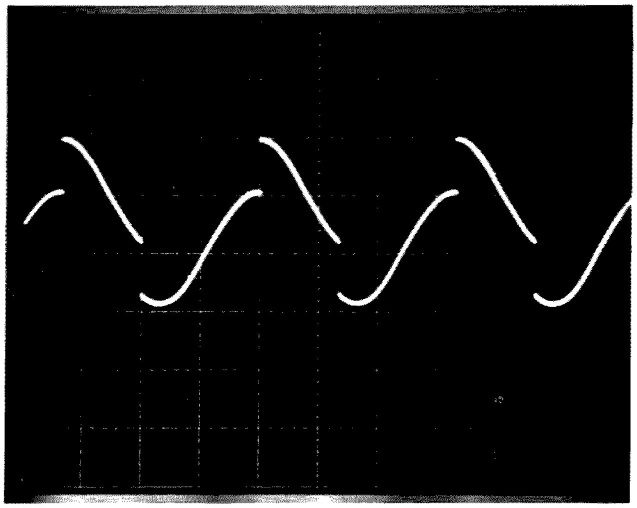

Fig. 5b. Mixed waveforms showing proper adjustment of R1 so IC1 triggers at line voltage peak.

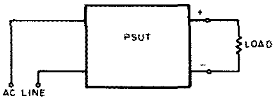

Fig. 6.

power supply. Fig. 3 shows the circuit; R1 sets the load current drawn from the power supply for any given value of R2. R2 is chosen to give about one volt output at the maximum load current to be drawn from the PSUT. C1 is an input from a pulse generator which causes the load current to increase sharply then decrease, varying over a small range. Because Q2 and R2 dissipate the entire power output of the PSUT, both should be mounted on a large heat sink.

The second gizmo allows a power supply to be switched on or off at a special time – either at line voltage zero crossing or at line voltage peak. If the PSUT will develop spikes at turn-on or turn-off, close examination of the PSUT output using an oscilloscope will reveal the problem. Fig. 4 shows the circuit; it is safer to observe the special precaution of using an isolation transformer. If such a transformer is not available, take strict precautions to insure, by measuring both circuit common and point "L" to a good earth ground, that circuit common is really the low side of the line. Circuit operation is simple; IC1 samples the transformer output and produces approximately a square wave. With SW1 in the 0° position, the rising edge of the waveform at "B" will occur at zero crossing. With SW1 in the 90° position, R1 can be adjusted so the trigger occurs at line voltage peak. The photos in Fig. 5 show the mixed waveforms (see Fig. 1) for zero crossing (Fig. 5a) and for switching at line peak (Fig. 5b). IC2 consists of two flip flops which are clocked by the output from IC1. If SW2 is open, Q1 and Q2 are both high; with SW3 in the T/ON position, Z1 is turned on and triac Z2 is turned off. When SW2 is closed, Q1 goes low on the next positive edge from IC1, and Q1 triggers the scope. On the second positive edge from IC1, Q2 goes low and Z1 turns off. Z2 is then turned on by current through the 47 Ohm resistor and any load connected to Z2 is activated. After R1 has been adjusted properly, the load can be switched at zero crossing or line peak by setting SW1 and closing SW2. With SW3 in the T/OFF position, Z2's load is activated until SW2 is closed, then Z2 turns off at the next zero crossing after FF2 switches.

Three types of tests should be performed on all unknown power supplies to give reasonable assurance of safe, reliable operation in a home computer system. These are: (1) transient detection and rate of rise; (2) dc regulation and heat rise; and (3) output impedance.

As mentioned above, power supply transients can disrupt or damage the CPU. In a computer system which uses several different voltages,

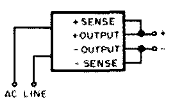

Fig. 7a.

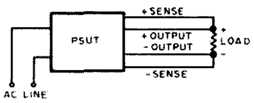

Fig. 7b

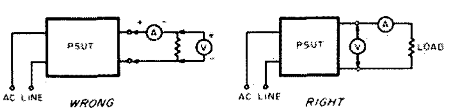

Fig. 8.

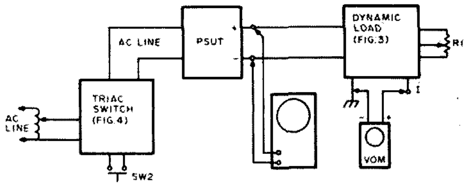

Fig. 9.

sections of the system may lock up or be damaged if (for example) the +15 volt bus comes up before the –5 volt bus. The rate of rise measurement allows the system designer to know if all supplies will come up together when switched by the same power switch.

The dc regulation test tells how well the regulator circuitry performs, and the heat rise test forewarns of possible fire or overheat conditions if the supply is used for continuous operation.

A test of power supply impedance tells how well the supply will decouple possible circuit interactions. A noisy Vcc line can be very bad for TTL logic and may cause subtle problems almost impossible to locate without a very good oscilloscope. Although decoupling on the board is helpful, it will not entirely overcome the effect of a high impedance power supply. Probably 90% of all decoupling would not be needed if a "perfect" (zero output impedance) supply were available. *However:* A "perfect" power supply feeding a load with 2' of #24 wire clip leads might have over an Ohm of impedance for fast logic signals.

Fig. 6 shows typical output connections for a modular, fixed voltage supply which does not have sense lines. Any stated performance specifications (% regulation, noise, ripple, etc.) apply *only* at those terminals. They will still be very close if the supply feeds a load via #8 wire leads. If the supply is feeding a home brew backplane wire wrapped with #30 wire, the top of the card 12 slots away may be in trouble!

Some of the connecting lead problems go away if the supply has sense leads as shown in Fig. 7. Sense leads must connect electrically as shown in Fig. 7a. If this connection is made physically at the supply, the equivalent circuit is the same as Fig. 6. If both the sense leads and load leads attach at the load as shown in Fig. 7b, the published specs now apply at the load.

Power supply test hookups must be carefully and properly made! Fig. 8 shows right and wrong connections – note that the "wrong" connection includes the effect of the load leads and the drop across the ammeter in the measurement. If you want to prove the importance of heavy power supply leads, repeat some of the tests outlined below using the "wrong" connection and #30 wire and check the difference.

Do the transient test first and discard or redesign any unit which fails. Use the triac switch of Fig. 4 with the connections shown in Fig. 9. *Remember the grounding precautions if an isolation transformer is not used.* With SW3 set to T/ON and SW1 set to 0°, sync the scope so the rising output of the PSUT is displayed on the scope as in Figs. 10a and 10b. Repeat the test for T/OFF (Fig. 10d) and repeat the T/ON test with SW1 set to 90° (Fig. 10c). OK the PSUT only if no spiking occurs under low, medium and full load conditions. If rate of rise is important to your system, measure it before dismantling the test setup. The PSUT shown in Fig. 10 was a surplus supply with a good pedigree; it is

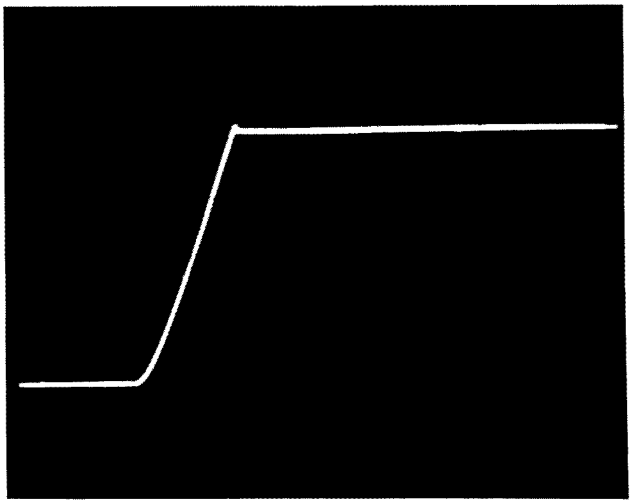

Fig. 10a. Turn-on of 5 V, 3 A power supply; 1.8 A load, switched at line voltage zero crossing. Time of rise – 3 milliseconds. Note rapid response to very minor overshoot.

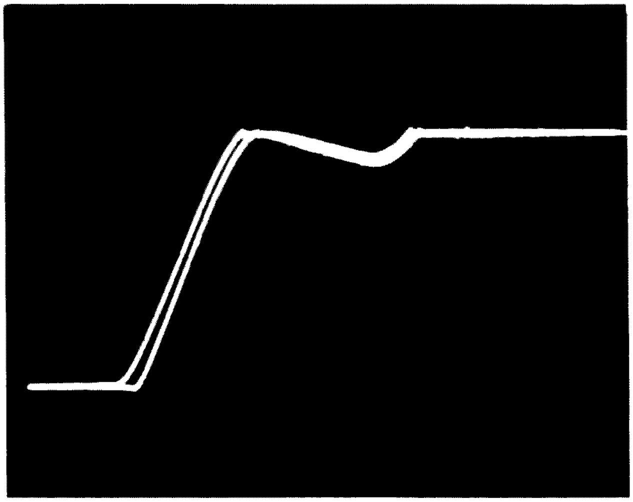

Fig. 10b. Double exposure of 5 V, 3 A power supply; 1.8 A load, zero crossing turn-on. Voltage irregularity caused by incomplete charging of filter cap on first cycle of line voltage. Note that voltage does not exceed set value more than 1%. Excellent regulator!

very gratifying to have such excellent test results from a supply which cost about half the going rate!

Set up the regulation test as shown in Fig. 11. Select R2 of the dynamic load (Fig. 3) for one volt drop at full rated load current of the PSUT, then read current with the VOM at output I. For example, if R2 is 1 Ohm, one Amp will give one volt across R2. Set the line voltage to 115 volts and set the reference supply to the same output voltage as the PSUT. Let the whole system warm up at 50% load (PSUT rating), then connect the VOM with the resistive network shown in Fig. 11. Set the VOM to the 50 microamp scale and adjust the reference supply so the meter reads zero. Close SW4 and readjust the reference supply for mid-scale on the meter. Now, 50 millivolts change in PSUT output will swing the meter to end scale. Lower the line voltage to 105 volts, note the VOM reading after one minute, then raise the line to 125 volts and note the change after one minute.

Percentage regulation is defined as

$$\frac{VH - VL}{VH} \times 100\%,$$

where VH is PSUT output at high line and VL is PSUT output at low line. Since this connection will measure the change in output, this reduces to the VOM reading in millivolts divided by the output voltage set on PSUT (an approximation, unless a digital voltmeter is available to measure VH). For 100 millivolts change (full scale swing on the VOM with SW4 closed) on a 5 volt supply, the % regulation is .1/5 or 2%. This is a "not good" unless the impedance test gives exceptionally good results. Even so, such poor regulation on a supply sold as a "regulated" supply may mean the regulator circuit has problems.

Repeat the test with line voltage fixed at 115 volts and change the load from no load to full load. Compute the regulation as before, using the change in output voltage as measured by the VOM and the nominal output voltage of the PSUT. Acceptable regula-

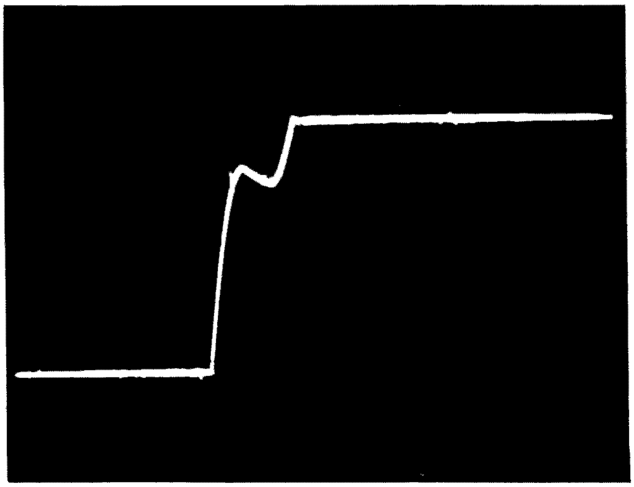

Fig. 10c. Turn-on of 5 V, 3 A power supply; 1.8 A load, turn-on at line peak.

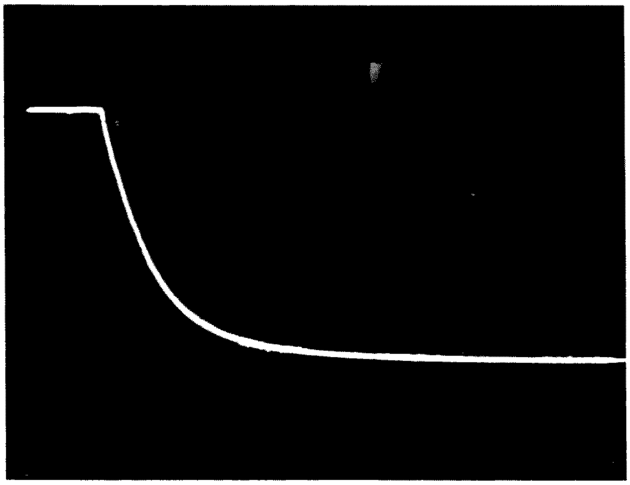

Fig. 10d. Turn-off of 5 V, 3 A power supply with 1.8 A load; total decay time – 150 milliseconds. Note complete absence of transients.

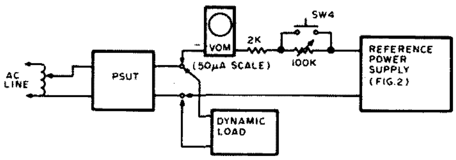

Fig. 11.

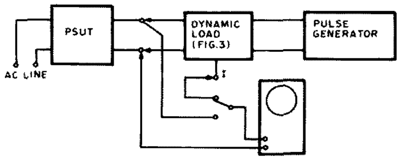

Fig. 12.

tion is .2% (10 millivolts change on a 5 volt supply), but .1% is better for most applications. For that supply with poor line regulation, repeat the no load/full load test at low line voltage and reject it for long-term use if the regulation changes substantially at low line voltage.

Run the heat test by pulling full load for several hours. The PSUT output should change very little, and no part of the supply should become too hot to touch. If the heat rise is too much or the regulation changes drastically, reserve the unit for smaller loads or intermittent duty. Sometimes it is possible to add heat sinks to overheating supplies, but heat-flow design is beyond the scope of this article.

The output impedance test also uses the variable load. In this case, set some mid-range load on PSUT, then feed a small amplitude square wave or pulse to the modulation input. Use the scope to monitor the I terminal on the variable load, and set the modulation drive so the current is changed by 10% of the fixed load current. Then move the scope to the PSUT output and look for output voltage changes at the modulation frequency. Measure both the current change and output change in voltage peak-to-peak and divide the voltage change by the current change. Output impedance is simply this voltage divided by the current. For example, assume the load current is 1 Amp, with a current change of .1 volt peak-to-peak. If the PSUT output changes by .01 volt peak-to-peak, the impedance is .01/.1 or .1 Ohm, a good value. Vary the pulse frequency over a fairly wide range to check for any major change in impedance. Most solid state supplies of good design will hold output impedance essentially constant over a wide frequency range.

Now that you have located a good supply with low impedance, don't handicap it! Run bus *bars* for power lines instead of wires, solder power connections everywhere except where they pass through connectors, use high quality connectors and choose or lay out PC boards with wide, multiple power runs. Even if the logic card draws fairly low power, fast logic generates fast transients. Small power conductors are inductive at much lower frequencies than large, flat conductors. Inductance in a power bus encourages interstage coupling, which spells *trouble* in any computer.

Power supply testing is so important that all computer hobby club members who home brew equipment should pool their resources to assemble a good test facility, then help each other check out all their power supplies. ■

A RTTY/Computer Display Unit

--Baudot, ASCII, TTL, RS232, etc., etc.

In order to interface man with computer, some sort of input/output device is needed. An extremely versatile output device is a visual display unit, which displays data on any modified television screen.

The display unit described in this article is very efficient, both in price and in the density of the data on the screen. It displays 25 lines of 40 characters each on the screen – almost double the density of most other display units now on the market. And the parts cost is less than \$100.00, buying from companies advertising in the back of this and other electronics magazines, including the price of the double-sided, plated-through board. All display unit parts, including the \$20 power supply, are contained on one 7.2" x 11.4" board. The option boards are both about 4" x 4".

The two option boards that are available are used to input serial ASCII and serial Baudot. The first accepts the serial ASCII, converts it to parallel, and enters it into the display unit's memory. It also accepts parallel data from a keyboard, etc., and serializes it. The serial interfaces can be either TTL, EIA RS-232C, or 20 mil loop compatible, all selected by two jumpers. The other option accepts serial Baudot code, converts it to parallel, and changes the code to ASCII. This ASCII data is then sent to the display unit. The inputs to the Baudot board can be either TTL, EIA RS232C, or 60 mil loop.

A useful feature of the display unit is called next line blanking. This causes the screen to be erased, line by line, as the cursor moves down a page full of data. If this feature was not in the display unit, after the screen had been filled with data once, you would simply be writing over old data, character by character. To say the least, this can be very confusing! Full cursor control is available using the "forward/backward" input. The cursor can be moved straight up or down, left or right, or to the left of the screen, and then up or down one line. A self-test line is available so that signals can be displayed on the screen; therefore, in most cases, an oscilloscope is not needed. All logic is done with standard TTL gates and dividers. There are no capacitively coupled lines or other bears to troubleshoot, so a person with a modest experience with logic will probably be able to easily fix his board, should it not work.

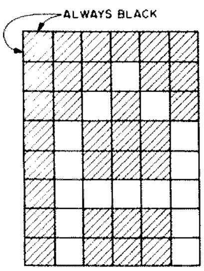

Fig. 1.

Basic Information

The 3320 display unit has a format of 25 lines consisting of 40 characters each. The characters are arranged in a standard 5 x 7 matrix, each space in the matrix being either a white or a black dot on the screen of the television. There is a one dot space both horizontally and vertically which is always

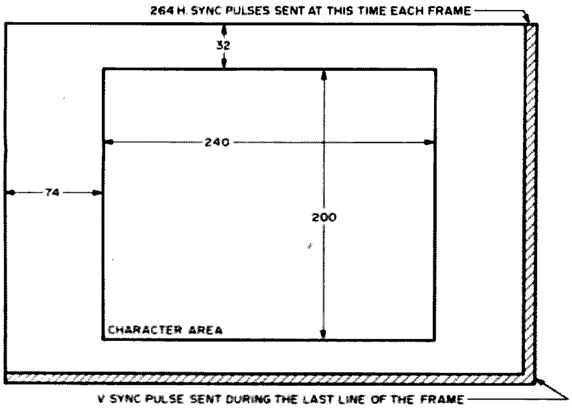

Fig. 2.

black to make sure that there is space between characters. Therefore, each character takes up a space of 6 x 8 dots on the screen, as shown in Fig. 1 for the letter "A". Each dot represents one cycle of the master clock.

The cursor, or the marker showing the next character position, is a white line five dots wide on the top scan line of that character, which is otherwise always black. The cursor flashes at a rate of two times per second to aid in finding it in a crowded screen.

Since characters take up 6 x 8 dots, and there are 40 characters on each of the 25 lines, there is a display area of 240 x 200 dots. There are provisions in the timing chain, however, for 384 x 264 dots. The reason for this is that the television's beam scans past the edge of the screen, where you can't see it. When it is well past the visible area on the screen, a horizontal or vertical sync pulse is sent which causes the beam to go back to the left edge or to the top of the screen, respectively. The display is centered within the 384 x 264 dot matrix, and fills up the visible screen of most television sets. This arrangement is shown in Fig. 2.

To interface the unit with the outside world, a parallel input and video output are provided. The input consists of seven data lines coded in ASCII, along with a strobe line. The strobe line is used to tell the display unit when to enter the data. When the strobe line makes its transition (either positive or negative, jumper selectable), the data is entered into memory. This strobe line is de-bounced on the board, and a strobe received pulse is available at the output connector. This is used by the input options and is required by some types of keyboards. The video output is a 2.25 V P-P signal with the specifications shown in Fig. 3.

Timing

The schematic diagram for the timing chain is shown in Fig. 16, while the timing chain is shown in Fig. 15.

All timing is derived from a crystal-controlled oscillator whose frequency is 6.082560 MHz. The output of this oscillator is called the A clock, and is fed into various dividers until it finally reaches the T clock, being 60 Hz.

The B clock is exactly half of the master clock, since it goes through the first flip flop in the divider chain. The C, D, and E clocks are all of the same frequency, but are different in phase. Since characters are six dots wide, there are six A clock pulses, three B clock pulses, and one each C, D, and E clock pulses. This is shown in Fig. 4 for the top of the letter "A".

The F clock is half of the D clock, and from the G to the J clocks, the previous clock is divided by two to get the present one.

The K clock is special, however. It is low when characters can be printed across the line and goes high when they can't (during horizontal retrace). There are enough clock pulses for 64 characters on a line, but only 40 of these are used. The extra 24 character positions cannot be displayed on most television sets, anyway, and are used for horizontal retrace. The K clock is not the output of a flip flop, but rather a latch that gets set on the 41st character and reset on the first character. In the middle of retrace (when the I clock is low), a horizontal sync pulse is created. This tells the television to send the electron beam back to the left side of the screen so that a new scan line can begin.

The K clock is divided by two, four and eight to get the L, M, and N clocks, respectively. These three clocks are fed to the character generator to tell it which scan line of the character the television is displaying. This is shown in Fig. 5 for the left side of the letter "A".

Note that the top scan line is always blank. This is to provide vertical spacing between characters, and to allow time for 40 characters of the page memory to be moved into the line memory.

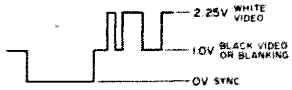

Fig. 3.

This is explained in detail in the memory section.

The last six clocks are different because they are reset at the end of the frame. There are provisions for 264 scan lines per frame (33 character lines of eight scan lines each). Since all dividers must be synchronized with each other, all affected counters are reset at the end of the frame, and the whole timing chain starts over.

As was mentioned earlier, there are provisions for 33 character lines, but only 25 of them are used. The T clock is low when characters can be vertically printed on the screen, and high when they can't (during vertical retrace). The T clock is like the K clock, in that it is a set/reset flip flop arranged as two cross-coupled NOR gates. The flip flop is set on the 26th line and reset on the first. In the middle of vertical retrace, the vertical sync pulse is created, telling the television's electron beam to go to the upper left hand corner of the screen and start a new frame. Several other timing pulses are derived from the lettered clock pulses, and they are explained in the cursor control and memory sections.

Fig. 7.

Memory

The memory schematics are shown in Fig. 19.

There are two clocks associated with the page (hex-1024 bit) memory, and one more is created for the line (hex-40 bit) memory. The main memory clocks are labeled Ø1 and Ø2, Ø1 being the output clock and Ø2 being the input clock. For every character that is shifted, both clocks have to be sent to the shift registers. These two clocks have to swing from +5 to -12, which are not standard TTL levels, and must not overlap. There is a clock driver between the timing chain and the memory to buffer these clocks. Since there are 1024 positions in the shift register, but only 1000 are used to display data, 24 extra clocks must be added somewhere in the frame.

These extra 24 pulses begin at the rise of the T clock, and end after 24 pulses have been counted by circuits 21, 13, and 22. These 24 pulses are logically ORed with the 1000 pulses that occur normally. The 1000 pulses occur during the scan line that is always black on the screen (L1), and only in the character area (the 240x200 dot area where characters are displayed). There are 40 of each clock per character line, where a character line consists of eight scan lines.

The line memory is clocked by the line clock which comes 40 times per scan line. During the top scan line of a character line (L1), the page memories are being clocked out, and that data is being clocked into the line memory. The data that was in the line memory is sent to the character generator, but since it is scan line number one, the output of the character generator is all zeros. On the next seven scan lines the data just fed into the line memory is clocked into the character generator over and over again.

The character generator is actually a read only memory that is addressed by the output of the line memory and the L, M, and N clocks which tell it which scan line the unit is now displaying. The output for the first scan line (L, M, N = 0) is always zeros, so the top scan line always is black. The output for the second scan line of the letter "A" would be 00100, the one being the point on the top of the letter.

The output of the character generator is sent to a shift register, which shifts the data out at the frequency of the A clock. The serial input of this output register is grounded so that during retrace its output is low, making black dots on the screen. The character generator's output is loaded into the output register when $\overline{\text{load}}$ is low and the A clock rises. Note that the first load pulse is created one character position after the other memory clocks start. This is because there is a long propagation delay between the page memory's and the character generator's outputs. The output of the shift register is sent to a buffer transistor where it is mixed with the sync pulses and is sent to the television.

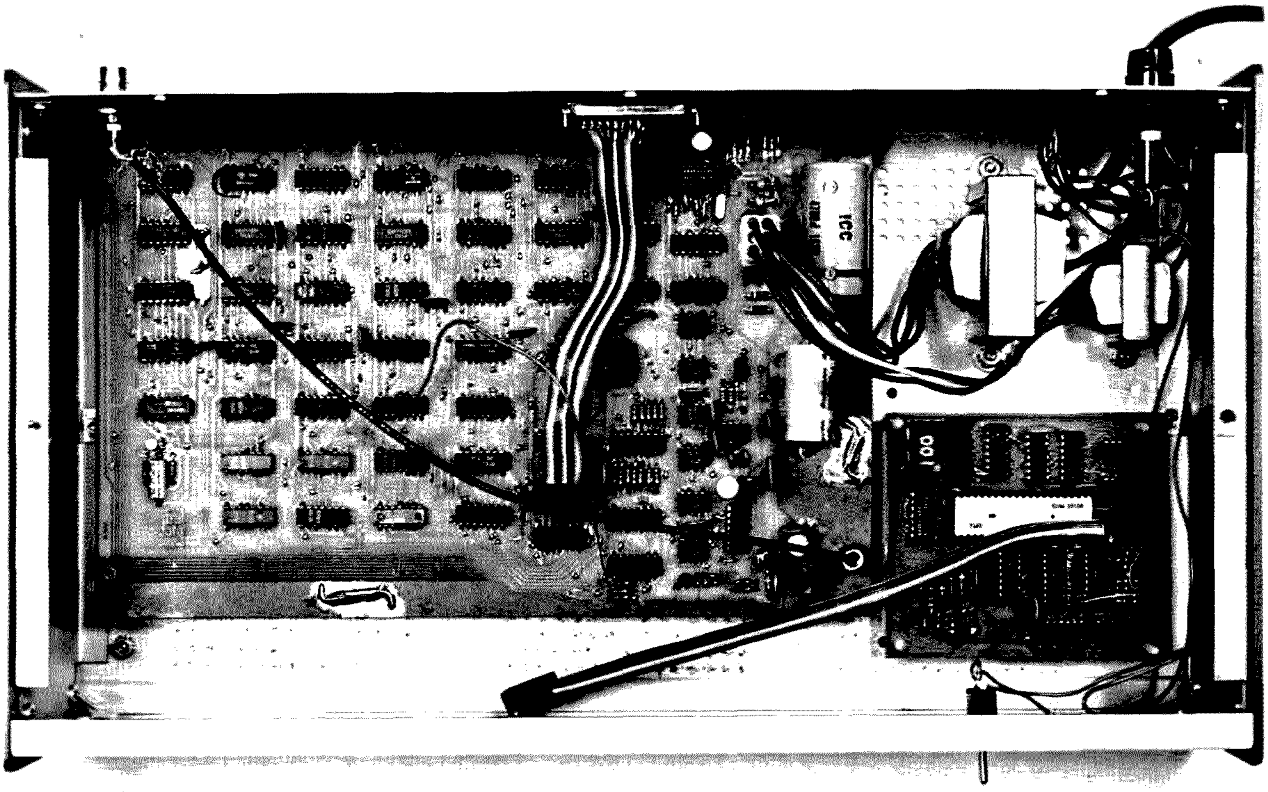
Input Conditioning

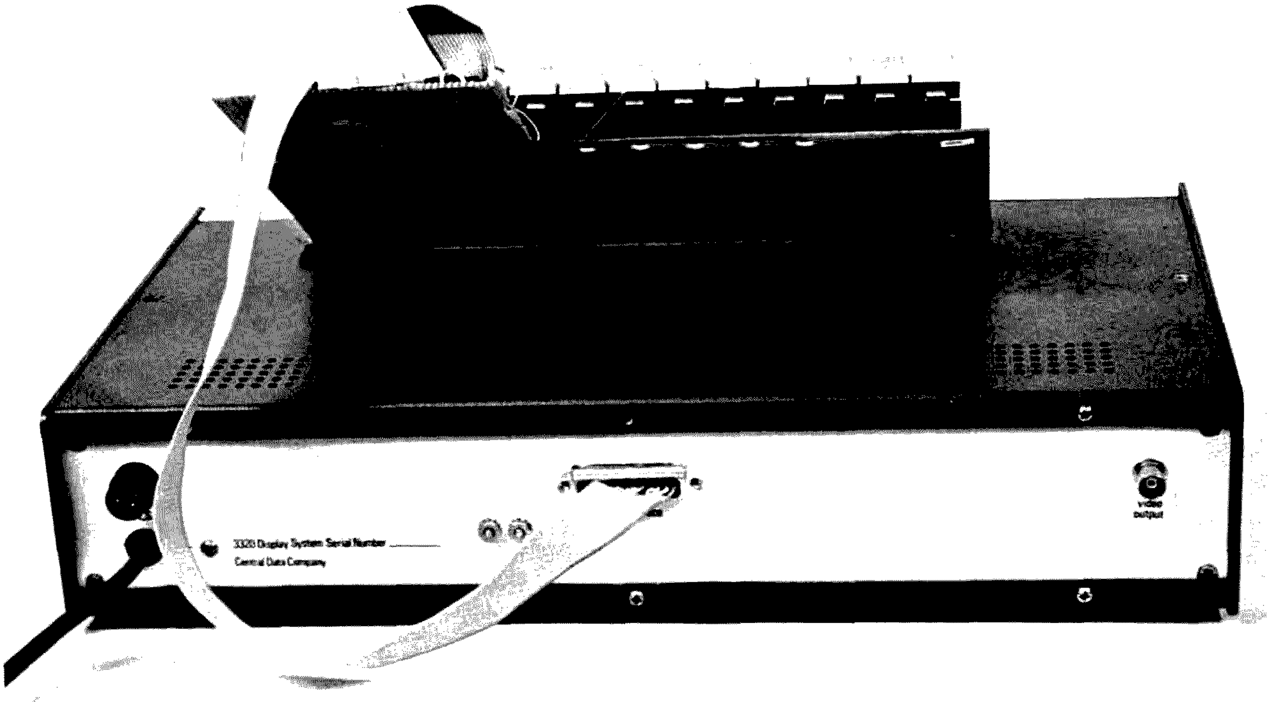
The input conditioning and cursor control schematics can be found in Fig. 17.

In order to enter the input data into the memory, it is required that a strobe pulse accompany the data. This pulse can be either negative or positive going, depending on the wiring of the strobe jumper. If it is a negative strobe, points A and C are jumpered as explained on the cursor control drawing.

The de-bouncer is the first type D flip flop in the chain. After strobe is received (pin 2 of 35 goes low), the device waits for the next rise of the S clock. When this happens, the output (pin 6) goes high. The reason that this circuit de-bounces is that the S clock has a period longer than any noise on the strobe pulse could last.

The sequence of events is shown in Fig. 6. Pin 6 of 35 is sent to the clock of the next flip flop. When it goes high, the grounded input is transferred to the output (pin 9), and that sets the NAND gate set/reset flip flop. When this flip flop's Q output (pin 8) goes high, its $\overline{Q}$ output goes low, running back through an AND gate and setting the second type D flip flop. Even though pin 9 of 35 now goes high, the set/reset flip flop stays set (pin 8 stays high). That output is sent to the input of another type D flip flop whose clock is the $\overline{T}$ clock. Therefore, when $\overline{T}$ goes high, pin 5 of 36 goes high and 6 of 36 goes low. Pin 6 of 36 is fed back to reset the set/reset flip flop, bringing pin 8 of 17 low. The next time the $\overline{T}$ clock rises, pins 5 and 6 will go back to





Central Data Company
video output

their normal states. Pin 5, therefore, goes high for exactly one cycle of the timing chain. The clear line sets the second and third type D flip flops to the correct states.

Pin 5 of 36 is sent to different parts of the cursor control section depending on the setting of the control bits. If bits 6 and 7 of the input data are not both low, a standard update cycle begins. This is where the input data is put into memory and the cursor is moved one position forward or backward. If, however, bits 6 and 7 of the input data are both low, a line feed (LF) cycle begins. If an LF cycle happens with bit one low, then a line feed is initiated (the cursor moves straight up or down one line).

If bit one is high during an LF cycle, the cursor moves back to the beginning of the line, and then up or down one line. In this case, a set to 40 pulse is created at pin 11 of 38 since bits 6 and 7 are both low (1 of 37 is high) and bit one is high. This status is ANDed with the up or down pulse (only created during an LF cycle) to arrive at the set pulse. The any cycle line is hooked directly to pin 5 of 36, so it goes high for one cycle after strobe drops no matter how any of the data bits are set. Fig. 7 shows the ASCII codes as used in the 3320 display unit.

Cursor Control

The cursor control section can be thought of as a chain of flip flops that divide their input by 1000. The clock for this divider sends a pulse during the first scan line (L1), above where each character could be. The divider is actually a divide by 40 chain placed in front of a divide by 25 chain. Since the total chain divides by 1000, and 1000 clock pulses are created each frame, the output of the last stage of the divider will drop once each frame. When this output drops, the cursor is displayed on the screen.

To move the position of the cursor, the divider must drop at a different time in the frame. This can be accomplished since the input of the divider can receive pulses from either the character clock generator or a special circuit that either adds or takes away pulses.

If an extra pulse is fed to the divider, the output will drop one character earlier. If a pulse is taken away, the output will drop later, since it will take longer to count 1000 pulses. Instead of taking away pulses, a long pulse is created that "covers" two normal pulses, as shown in Fig. 8. So if we want to move the cursor back one position, an extra pulse is added between the normal character clock pulses. If we want to move the cursor ahead one position, we cover up two pulses by adding one long pulse. The pulse, whether short or long, is created when the update cycle drops, setting pin 9 of 22 high. Pin 9 of 22 goes low the next time that the E clock rises, and will stay low until the update cycle drops again. If the FWD/BKWD line is high, this pulse goes through an AND gate to set a set/reset flip flop, IC23. The next time that the G clock goes high, the set/reset flip flop gets reset. This flip flop, therefore, stays set for the first two character positions of the frame. The output of this flip flop is called the forward pulse.

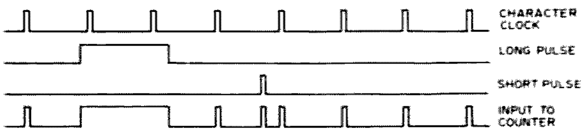


Fig. 8.

When pin 9 of 22 is high, an A clock pulse is sent through an AND gate to pin 12 of 20. This pulse is called the backward pulse. Even though it seems that two pulses would come out of this gate each update cycle, only one does. This is because there is a propagation delay between the A clock and the T clock. Because of this small delay, the T clock (and the update cycle) drop in the middle of the first C clock of the frame. Therefore, the very first A clock pulse of the frame does not get through to pin 12 of 20, but the second one does. By the time that the third A clock pulse comes, pin 9 of 22 has been reset to 0. The one short pulse that does get through is called the backward pulse.

The character clock, forward pulse, and backward pulse are all ORed together to form the input to the divide by 40 chain. If there wasn't just an update cycle, only character clock pulses get through. If there was just an update cycle and the FWD/BKWD line is low, the backward pulse will also get to the clock of the divider. This will clock the divider one extra time, so its output will drop one position earlier. If there was just an update cycle, and the FWD/BKWD line is high, the forward pulse gets through and covers the first two character clock pulses as well as the backward pulse. There is one less clock pulse this frame, so the divider drops later.

The divide by 40 chain consists of circuits 30 and 31, and its output is pin 11 of 31. When this output drops, it clocks pin 6 of 32, setting pin 11 to a low state. On the next character clock pulse this flip flop is set (pin 11 goes high) and stays that way until the counter drops again.

The divide by 25 chain operates the same way that the divide by 40 chain does, as far as adding pulses to move the cursor. To move the cursor up, an extra pulse is added, making the divider drop one line earlier. If the cursor is to move down, a long pulse is created to cover up two normal pulses. The normal clock to this divider is pin 11 of 32, which goes through IC28 to get to the divider (circuits 33 and 34). The dropping of the LF cycle line sets off the extra pulse generators in the divide by 25 counter chain. It sets pin 12 of 24 high, but that pin is soon reset when the E clock rises. If the FWD/BKWD line is high, the pulse from this flip flop goes through an AND gate and sets a flip flop, circuit 27. The $\bar{Q}$ output (pin 4) of this flip flop goes low immediately and rises again when the P clock goes high. The $\bar{Q}$ output of this flip flop is therefore low for two character lines (16 scan lines), and is called the down pulse. Pin 12 of 24 also is ANDed with the A clock to create a short pulse (the up pulse). The reason two pulses are not created is the same as was explained for the divide by 40 chain.

The up and down pulses, along with the normal clock from pin 11 of 32, are run through an AND gate and sent to the clock input of the divider. If a line feed cycle has just happened, and the FWD/BKWD line is low, the short pulse from pin 12 of 26 is added on to the normal clock pulses, causing the cursor to come one line earlier. If the FWD/BKWD line is high, the long pulse from pin 4 of 27 covers the first two normal clock pulses and the up pulse. Note that the up and backward pulses come even if the FWD/BKWD line is high, since they will be blocked out by the down and forward pulses anyway.

The divide by 25 chain consists of circuits 33 and 34, and its output is pin 11 of 34. This output is the clock input

to a J-K flip flop, pin 1 of 32. When the output of the counter drops, the flip flop changes states, and pin 14 of 32 goes high. This flip flop is reset by the next character clock pulse, so pin 14 of 32 goes high for only one character width.

This line is called character position and goes to the chip enable of the character generator, which causes the generator's output to go high (display white on the screen). This is the cursor, and it goes to a blinker circuit before it gets to the character generator, which switches it off and on at the rate of about two times per second.

The character position line is ANDed with the update cycle and that pulse is sent to the page memory location that it is now at. The memory therefore gets changed during the update cycle, while the position of the cursor gets changed during the frame immediately following the update cycle.

To clear the display and move the cursor to the upper right hand position of the screen, the clear line is brought high. This brings the write line of the page memory high. It also brings the input to the memory bit 6 high. All keyboard data is gated to the memory inputs only when the update cycle is high, so the other five data inputs will be low. The ASCII code for a space is all bits low except for bit 6. So what will happen is that the memory will take the input data (space) and keep putting it into memory until the clear line goes low. If the clear line was high long enough to allow all of the memory positions to be accessed (1/60 second), the memory will be filled with blanks.

Now that the screen is blank, the cursor has to be moved to the first position of the page. To do this, both of the cursor divider chains are set to all ones; on the next clock pulse the divider's

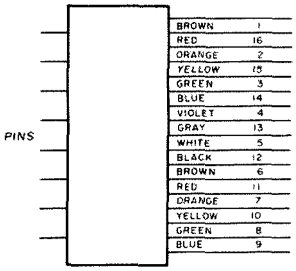

Fig. 9.

outputs will drop, displaying the cursor. A set/reset flip flop is set when clear goes high, and its output (pin 13 of 27) is used to preset the divider chain. Since the first clock pulse that gets to the divider must be at the beginning of the frame (so the counter will drop after the first clock pulse, or in the first character position), the preset line must go back to its normal state at the beginning of the frame. The preset line goes low the first time that the $\overline{T}$ clock goes low, after clear drops. Since the $\overline{T}$ clock goes low at the beginning of the frame, so does the preset pulse, and the dividers are now clocked.

Next Line Blanking

The next line blanking schematic can be found in Fig. 18.

The next line blanking circuit makes sure that, after you fill the screen and are about to start writing over old information, old information gets erased. It clears the screen line by line, as the cursor moves downward.

The lines get "blanked" under the following two conditions:

1. If the cursor is detected in the first character position of a line. In this case, the line that the cursor is on gets filled with blanks.

2. If a line feed is initiated. (The cursor moves straight down.) In this case, the line below the cursor's gets filled with blanks. Therefore, after the line feed is finished, the cursor is on the blank line.

To find whether or not the cursor is in the first position of any line, character position is ANDed with a signal that is high only in the first position of each line. This signal is pin 12 of 40, which is a J-K flip flop that gets set at the beginning of a line and reset after the first character position of the line is passed. Since the first $\overline{\text{load}}$ pulse lags behind the first line clock pulse by one character (as explained in the memory section), when both of these are high, and we are in the character area, we are also in the first position of a line.

As was stated earlier, this pulse is ANDed with character position, and if it is not "any cycle" or the frame right after it, it is used to set a flip flop (circuit 43). This flip flop's output (pin 13) is reset to zero the next time the K clock goes high (at the end of the scan line). This line goes on to bring the write line of the memory high, along with the bit 6 input, so that the memory gets filled with spaces. Since this line goes high at the beginning of a scan line and drops at the end of it, 40 locations of memory get filled with spaces. The memory gets written with spaces every cycle that the cursor is in position one.

In the second case, if an LF cycle occurs, it is ANDed with character position to set a flip flop (circuit 43). This will bring pin 4 of 43 high, and will allow the next flip flop (circuit 24) to toggle. This will happen the next time the N clock drops, or at the beginning of the next character line. This pulse is fed back to the first flip flop and resets it. The line is reset the next time that horizontal sync goes low. Therefore, the line goes high for almost one scan line, on the character line below the line where the cursor now is. (Remember that the cursor moves after an LF cycle drops.) This line also is fed to the write line of the page memories and to set bit 6 of the inputs high.

To turn the next line blanking feature off, jumper on the board the two pads marked NLB. This grounds pin 11 of 29, and doesn't allow a write pulse to go to the memory.

Power Supply

The power supply schematic can be found in Fig. 14.

The power supply has provisions for +5, -5, and -12 volts at 2, .15, and .5 Amperes, respectively. The +5 supply consists of a 12.6 V, 2 A, C.T. transformer whose output is rectified and filtered and sent to two 7805 (LM340T-5) regulators. The two regulator chips are mounted to the cabinet and are hooked up in parallel.

The -12 supply is obtained by rectifying and filtering a 28 V, .85 A, C.T. transformer and feeding it into a 7912 (LM320T-12) regulator chip. The output of this chip is -12, and that output is sent to the -5 regulator. This consists of a zener diode hooked to the base of an MJE370 transistor. The output is between -5 and -6 volts.

All outputs are filtered with .1 disc capacitors and 100 uF electrolytics to improve regulator response and to filter out noise.

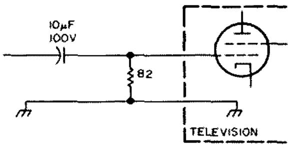

Fig. 11.

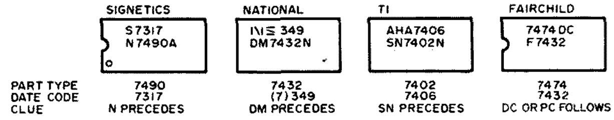

Fig. 12.

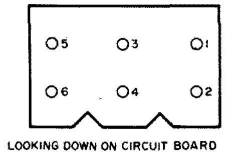

Fig. 13.

Troubleshooting

Power supply: When the board is finished, the power supply is not connected to the logic circuits. This prevents high voltage from ever reaching the integrated circuits, unless the power supply fails after it is initially tested.

To test the power supplies, the transformer is plugged into the board (through the molex connector) and the voltages are measured at the terminals marked +5, -5, and -12. If all of the voltages are correct (according to the table below), the three sets of pads can be jumpered, and the voltages measured again. If the voltages are still OK, the logic test procedure can begin. If not, you should start checking for solder shorts on the power supply lines.

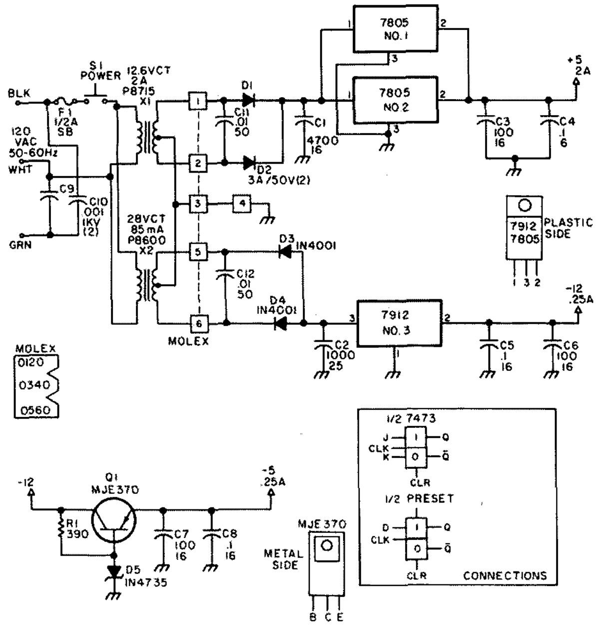

Fig. 14. Power supply.

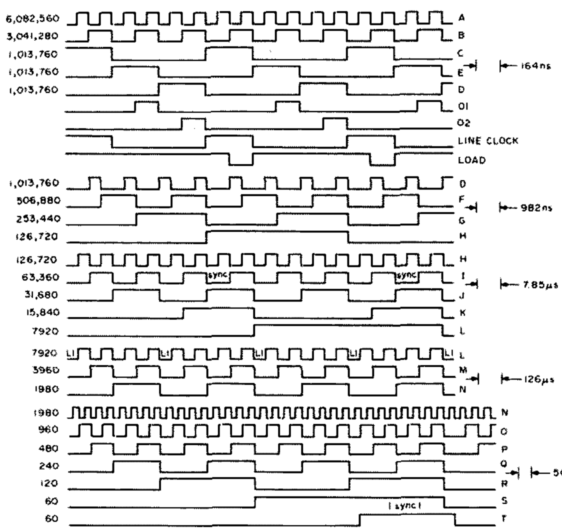

Fig. 15. Timing chain.

	Max.	Min.
+5	4.75	5.25
-5	-4.80	-5.90
-12	-11.7	-12.3

Logic testing: The 3320 display has a self-test feature which makes troubleshooting much easier. With this you can see any pulses that happen in the "visible" area of the frame. The visible area means any area of the frame that can be displayed on a television. Therefore, you can't see the sync pulses, and you must have these pulses to be able to display anything at all.

To use self-test, disconnect the jumper between the output shift register and pin 1 of 56 (between points D and E). This will take any video data that you may have off the screen. Next, connect pin 1 of the input connector to the signal line that you want to check. There should be a series of horizontal (for slower clocks) or vertical (for faster clocks) lines on the screen, where white is a logical one and black is a zero. To be sure that sync is there, and to be sure that the display is hooked to your television correctly, follow the above procedure and hook your jumper to a moderately fast clock (such as the G clock). In this case you should see 10 or 11 pairs of black and white vertical bars on the screen. If nothing is there, first check the connection to your television; if you're sure that's OK, you will need a scope to check the sync pulses and the output of the buffer transistor. After you get self-test working, go through any circuit that you think is bad and look at all of the signals. Please note that only TTL level signals can be displayed using self-test, so don't look at the output of the page memory's clock driver, or either of the negative supplies!

If the unit does not work, the first thing to check is the timing chain. The T clock should be 60 Hz (one horizontal line on the screen). If it is not there, start at the A clock and work your way through the chain. If the master clock is not oscillating, be sure that IC1 is a 7404 made by Texas Instruments. If it is not, it must be replaced with one that is. If the timing chain is all right, check the Ø1 and Ø2 clock pulses at pins 3 and 11 of 19, respectively. There should be 1024 small white dots on the television screen. If there are only 1000, check the divide by 24 circuit, ICs 21, 13, and 22. If there are dots all over the screen (many more than 1024), make sure that character area is high only for the area shown in Fig. 2, and that the divide by 24 circuit is working. L1 should be one horizontal scan line out of eight white, while load should be somewhat similar to the C, D, and E clocks, except the pulses will only appear during character area.

If everything seems to be OK in the timing section, check the cursor control. If a cursor appears on the screen, but won't move when pulsing the strobe line, first be sure that the jumper is in for positive or negative strobe! Then, see if there is a pulse at pin 5 of 36 that lasts exactly one frame (it will appear as a flash on the screen). If this pulse is not there, try clearing the unit by bringing the clear line to +5 volts. Because of the random states that logic

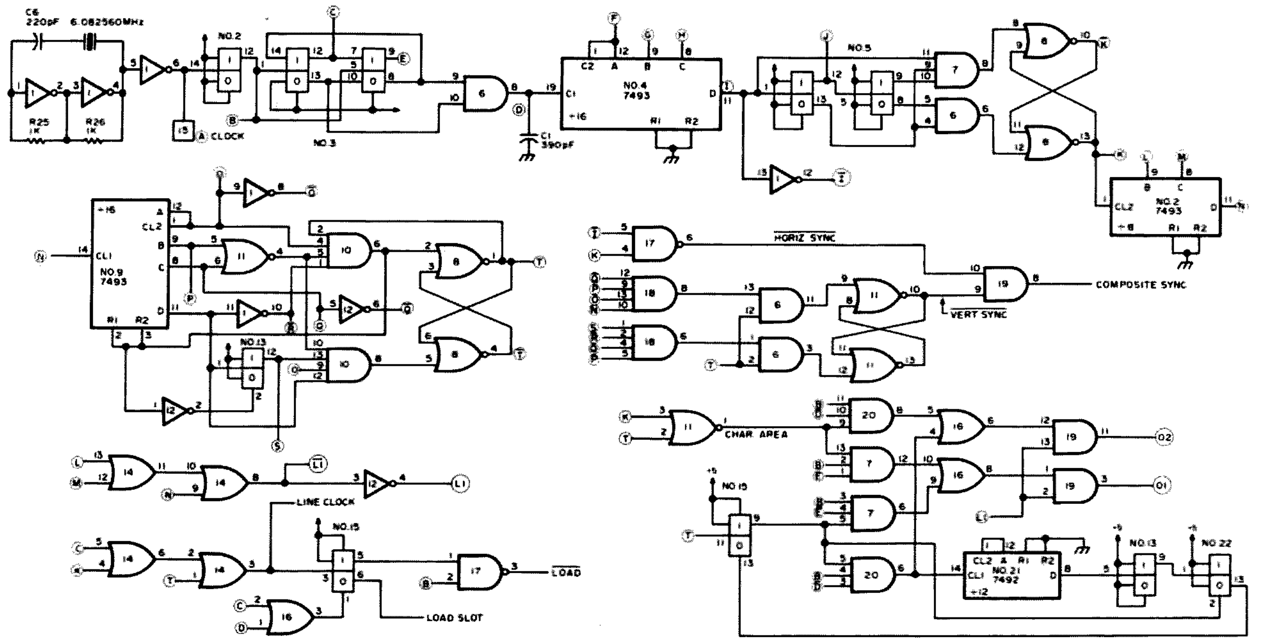

Fig. 16. Timing.

comes up in, some units must be cleared before data can be entered.

If a cursor doesn't appear, look for a character clock (1000 pulses on the screen) at pin 11 of 25. Be sure that this is clocking the flip flops and the divide by 10 (ICs 30 and 31). There should be 25 short normally high pulses per frame at pin 11 of 32. These 25 pulses are sent through an AND gate to clock the two divide by five circuits. If nothing is clocking, check the clear lines to the flip flops and the dividers. The output of the second divider (IC34) should cause flip flop IC32 to toggle once per frame. This flip flop will soon be reset by the next character clock pulse. This line is called character position, and is used to put the cursor on the screen and to bring the write line of the memory high during an update cycle.

If the timing and cursor sections both work, but the memory either won't enter data, won't fill with spaces when the clear line is brought high, or is creating random characters on the screen, the

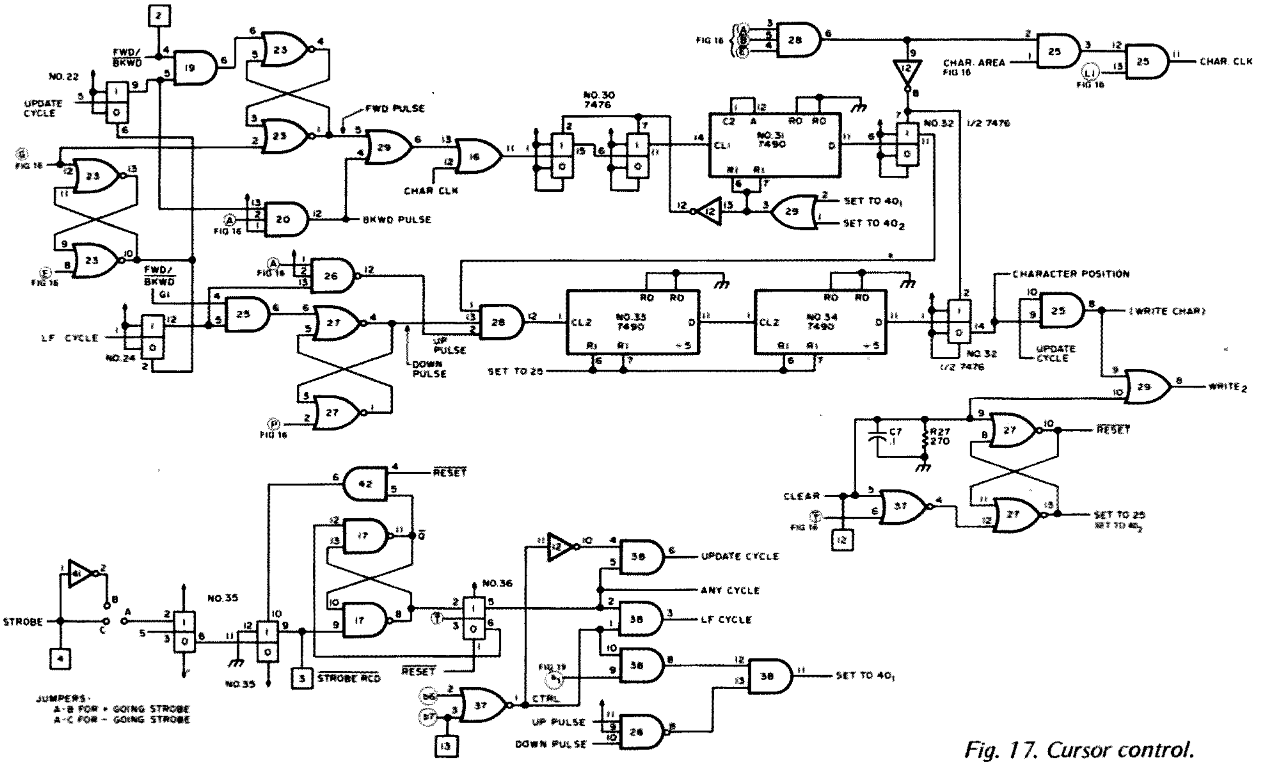

Fig. 17. Cursor control.

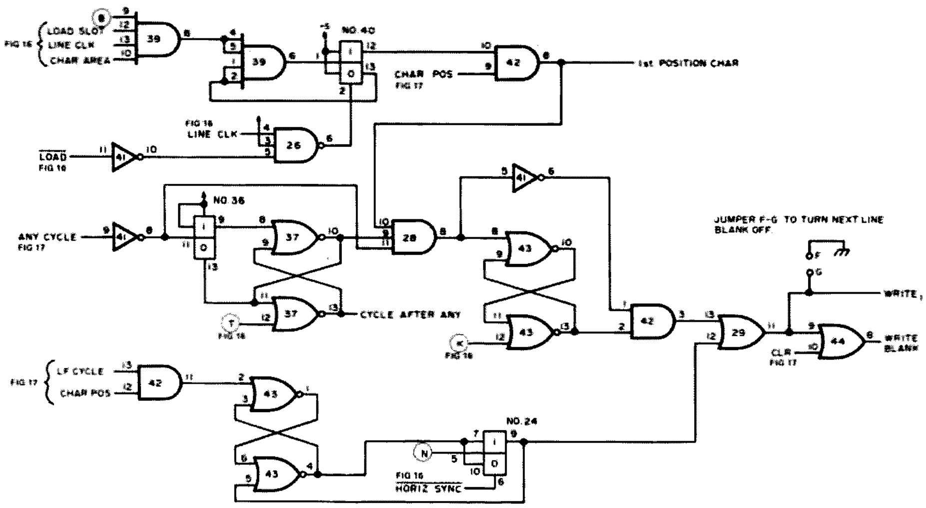

Fig. 18. Next line blanking.

memory section of the unit must be checked. First, if the screen has a series of vertical white lines on it, check pin 11 of 53 for a low. If it is not low (it should go high for a brief period to display the cursor), the character generator chip is not enabled and all ones will appear at its output. If this is not the problem, check all of the TTL level clocks such as L1, Ø1, Ø2, A clock, and the line clock. If these seem all right, check to be sure that the write line (pin 5 of circuits 46-51) goes high for a very short period during an update cycle. If it does not, check back through the circuit for the two write lines to see where they stop working. If everything is OK so far, you will need an oscilloscope to check the outputs of the clock drivers, circuit 45. There should be very little overshoot on these two clocks, and they must swing from about +5 to -12. *Do not look at these high level clocks with self-test. If this was done, circuit 56 must be replaced.* If the screen has a lot of characters that are shifting randomly, be sure that there are 1024 clock pulses at pins 11 and 3 of 19. If there are 1024 pulses per frame (on the screen), you must check the high level clock pulses from the clock driver *with an oscilloscope.*

If everything works except the next line blanking, be sure that you did not jumper the NLB pads on the circuit board, which will cause the next line blanking feature to be turned off. If the feature works with a line feed but not for a character in the first position, move the cursor to the first position of any line and check for a short pulse at pin 8 of 42. There will only be one pulse per frame. If it is not there, be sure that pin 2 of 40 is not always grounded, causing the flip flop to stay cleared, and that the same flip flop is being clocked at pin one. If that pulse is OK, see if it is getting through if it is during an update or line feed cycle (any cycle) or is the cycle after such. Pin 9 of 28 goes low for the cycle after any cycle. The pulse at pin 8 of 28 sets a set/reset flip flop, circuit 43, at pin 8, which brings the write line high. The line goes low when the K clock comes again. If the unit does not blank the next line after an LF cycle, see if the flip flop, circuit 43, is being set at pin 2, making pin 4 go high. If it is not, be sure that pin 5 is not always high, holding it reset. If pin 9 of 24 is always low, be sure that pin 10 of that circuit is not pegged low, keeping the flip flop cleared. The output of this flip flop also goes to set the write line high for one line.

If you find that a circuit is "bad," first check the following things:

1. That the power supply and ground are at acceptable levels on the chip.
2. That all of the input signals are within TTL specifications (low is less than .8 V; high is greater than 2.4 V).
3. That there are no unsoldered pins to the circuit, and no etch or solder shorts between a wire running to the chip and something else.

A large number of problems can be solved by checking these things before replacing an integrated circuit.

Operation

All connections to the keyboard and video monitor are through a DIP plug and a

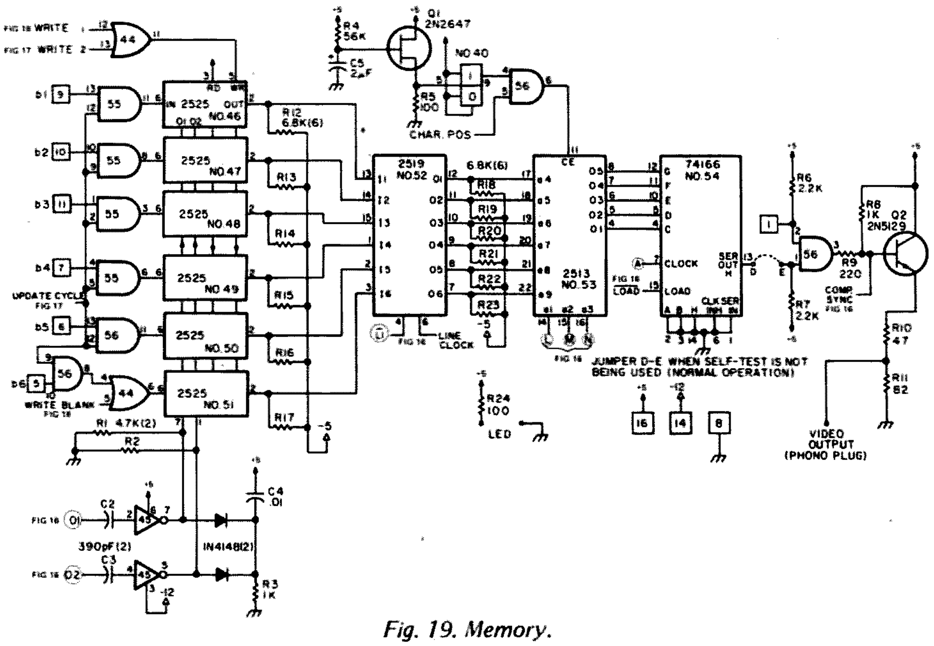

Fig. 19. Memory.

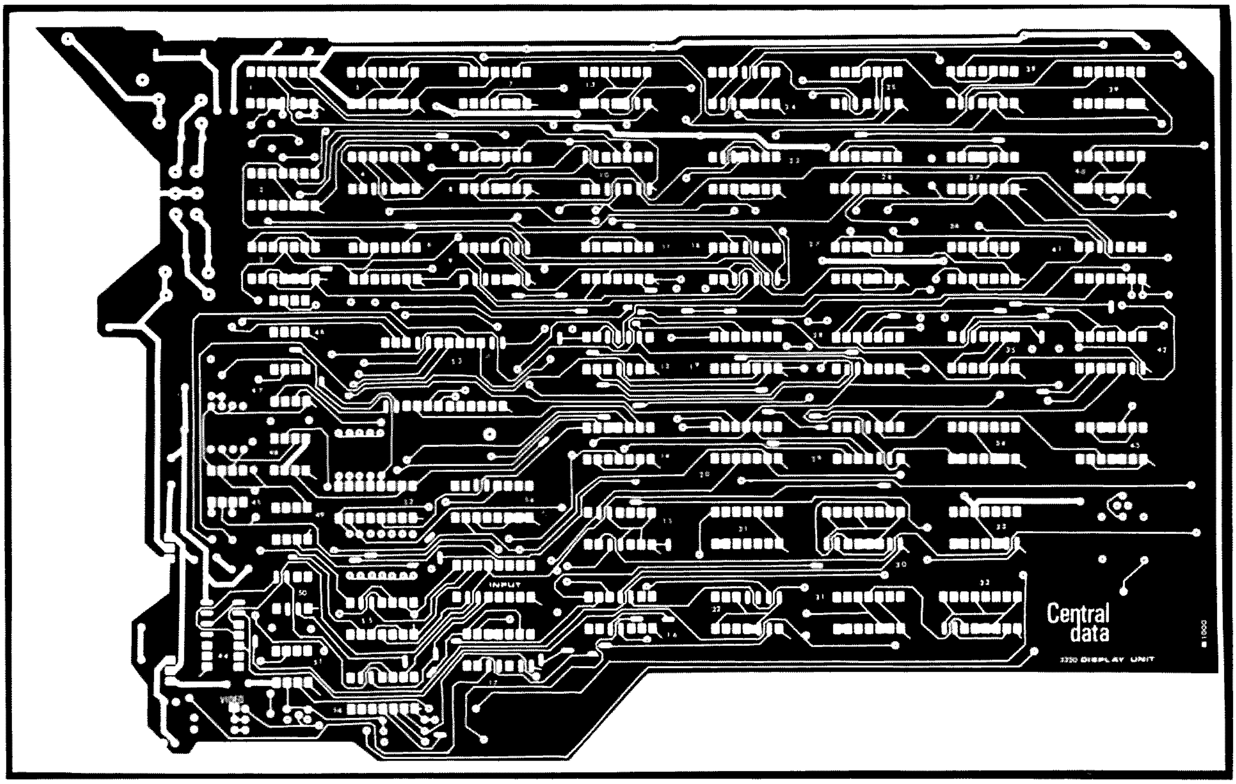
phono plug, respectively. The phono plug goes directly to the input of your monitor. It is the 2.25 V composite video signal whose waveform was given in Fig. 3.

The other connector consists of a 16 pin DIP socket soldered to the board, along with a cable that has a plug which will fit the socket. The cable's wires correspond to the pins on the plug as is shown in Fig. 9.

The signals that are available at the socket are listed in Fig. 19, the memory schematic. The $\overline{\text{strobe received}}$ signal is an output that acknowledges receipt of



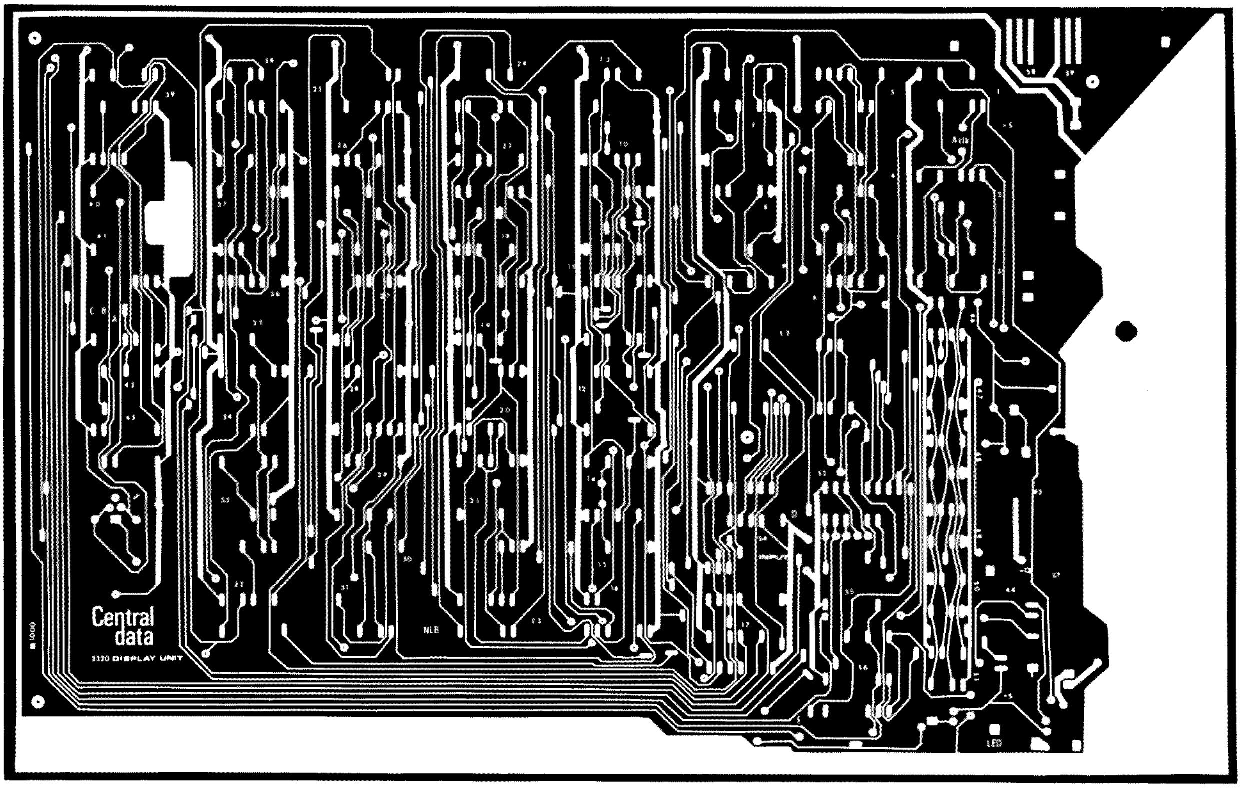


Fig. 20. PC board and component layout.

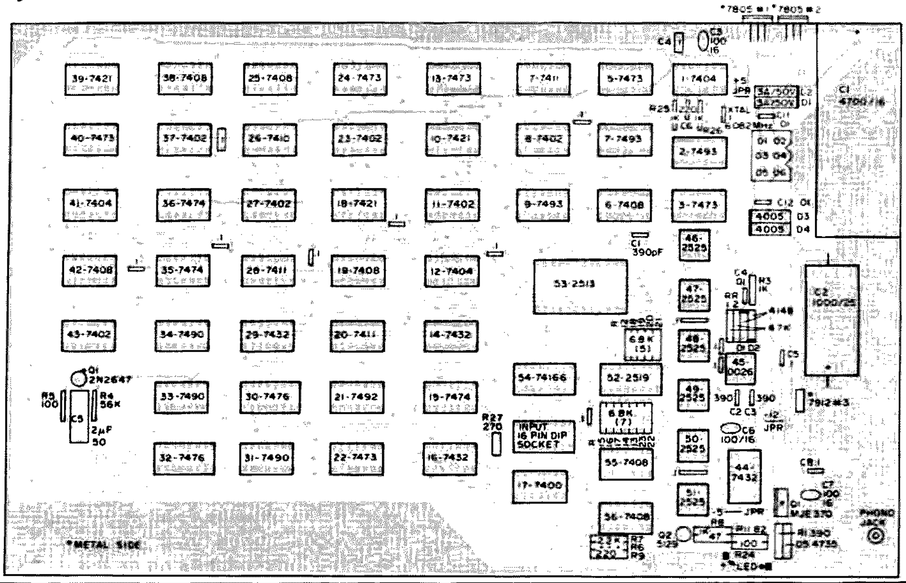

the strobe signal. It is a very short pulse that is used by the input options as well as some types of keyboards. Bringing CLEAR high will empty the screen and move the cursor to the upper left hand position. Sometimes, because the logic comes up in random states, the unit will have to be cleared before it will operate.

FWD/BKWD is an input that decides in which direction the cursor will move. If it is high, the cursor will move forward or down, while if it is low the cursor will move backward or up.

If you have an input option there is another DIP socket on the small option board which matches the one on the main board. The cable in this case had a DIP plug on both ends.

Modification of Your Television

WARNING: Do not attempt to use as a video monitor any television that has one side of the ac line connected to the chassis or to ground. To connect such a television will probably cause major damage to your display unit. The modification procedure is simply a matter of capacitively coupling the video output from your display unit to the first video amplifier stage of your television.

If you have a transistor television, use the circuit of Fig. 10 as a guide for the modification. If you have a tube type set, the circuit of Fig. 11 can be used.

With the tube type television, a higher voltage may be required to provide adequate contrast. A video amplifier can be inserted between the video output and the capacitor to solve this problem. With either set, there is a small possibility that it requires positive sync polarity. Since the data is transmitted with negative sync, a video inverter must be

Assembly: General Information

The circuit boards used in the 3320 display system are all double-sided with plated-through holes. Because of this you only have to solder the components on the bottom of the board. The plated-through holes make the connection to the top of the board. The components should be soldered with a low wattage (40-60 W), moderate temperature (approximately 750°) soldering iron. The iron should also be grounded when soldering the MOS integrated circuits. This is not absolutely necessary, however.

Be sure to mount all integrated circuits according to their pin one mark, not their lettering. Occasionally a circuit is lettered upside down. Most ICs are printed with both a part number and a date code. The date code consists of the year and the week that the circuit was produced. Example: January 30, 1977=7705.

The placement of the part number and date code for most circuits is shown in Fig. 12.

Also, be very careful to prevent solder shorts. This type of problem is very difficult to find later, so if it is done with care now it will save you a lot of time when troubleshooting.

Note that all pin one markers on the integrated circuits are towards the lower left hand corner of the board, except for circuit 44, which is toward the lower right hand corner. IC1 must be a Texas Instruments circuit; otherwise you are not assured that your master clock will oscillate. A square pad on the top of the board indicates the cathode (banded) end of diodes and the positive end of electrolytic capacitors.

Be sure to jumper the two terminals marked "A clk" near circuit 1. If you ever want to run your display off an external clock, break the jumper and connect the external clock to the lower pad. Also jumper the correct pads between circuits 41 and 42 corresponding to the polarity of your strobe pulse. If you are running off an external power supply, wire your power supply to the circuit side of the three sets of pads marked +5, -5, and -12. Also jumper pads D and E to connect the shift register to the buffer transistor.

A phono jack is installed in the ¼ inch hole, and a jumper is made between its center and the pad on the bottom of the board marked VIDEO. Connection to your monitor can be made using a phono plug and some RG-174U cable.

If you are going to use the on-board power supply, follow the parts placement diagram shown in Fig. 20. Be sure to mount the 7912 and the MJE370 transistor on heat sinks. The two 7805 regulators must be mounted at right angles to the board, and must be attached to a heat sink at least 4" x 9" x 1/16", if aluminum. To mount the regulators to the board, bend the leads (where they taper off) at a 90° angle. Then put some solder on each of the leads, along with the pads on the circuit board where they will be mounted. Then set one regulator on the circuit board and, one by one, heat the leads so that the solder melts and attaches the lead to the board.

Solder the transformer leads to the off-board molex connector using the configuration shown in Fig. 13. Two .001 disc capacitors should be placed across the power line to prevent high frequency noise from leaving the unit through the line. ■

Your Computer Can Talk Morse

-- even a computer can learn the code!

So you have that new-fangled "computer" in your shack. You are through with the headaches of wiring it and you have gotten past the frustration of programming it to type out your name. You are even to the point that you understand some of the games that came with it so well that you can cheat the machine. What's that? You want to try something else? How about calculating Oscar orbits? No. Well . . . how about true bearings and distances to DX contacts from longitude and latitude information? No? You want it to do something, not just arithmetic.

I've got it! You've been wanting one of those keyboard to Morse code units. Why not program the computer to convert ASCII to Morse? Then you could send prepared text, CQs, or just copy from the keyboard that you have. Say again, OM? How? Oh, sure, I remember a few ways to convert data. OK. Here goes . . .

First, you need a method of generating the Morse characters. You need some way for the computer to turn a relay or TTL circuit on and off. From there, you can drive the keyed circuit in your rig. Sorry, I can't help you with the hardware. Maybe one of the other fellas can help.

Next, you need some way to time the on and off periods. A timing loop. You never heard of a timing loop? Every instruction in the machine takes a certain amount of time, right? Let's assume that we have a routine (a short program segment) that will place a number in a register, then subtract one from the register, then check to see if the number left in the register is zero. If the result is not zero, the routine returns to the subtract instruction. If it is zero, then it executes the next step of the program.

What has the routine done? Nothing, really, but that is the point. The computer has been twiddling its thumbs for as long as it takes to count down that register. Now, if it takes 30 microseconds to subtract one from the register, test the register for zero, and branch back to the subtract instruction; then by changing the number that you start with, you can adjust the timing. (If you start with

Table 1.

6000 that will give 6000 x 30 usecs = 180,000 usecs or 180 msecs.)

Now, suppose that we take a number, like 117, and divide it by 4 (generating the quotient and the remainder). Q = 29; R = 1. If the remainder is a 1, send a dit; if it is a 3, send a dah. Now take the quotient and divide it by 4. Q = 7; R = 1. Again we send a dit. Divide the quotient again by 4. Q = 1; R = 3. This time we send a dah. Again, divide by 4. Q = 0; R = 1. Another dit. Divide again by 4. Q = 0; R = 0. This time the result is zero, which is the signal to stop sending the character. Dit dit dah dit came out F the last time I heard it.

Table 1 contains two lists. The first is a list of characters. The second is a list of the numbers that correspond to the characters in the first list. Notice that some of the characters do not have ASCII symbols. You will have to assign them some arbitrary symbol from your keyboard if you want to use them.

Now, to convert the ASCII code to the number set that I have shown you. There are two ways to program the computer to look down the table of numbers. The first is to treat the ASCII character you are trying to convert as a binary number that can be modified by arithmetic into another number that will specify to the program the position in the number table of the proper number for the original ASCII character. It is not really as complicated as it sounds.

The second method is to have a second table in the computer that contains ASCII characters in the order shown in Table 1. The program then steps down the character table looking for the proper ASCII character. When it is found, the program then looks the same number of steps down the number table, and there it is!

The only thing left to do is get the next ASCII character, and start the table lookup all over again.

Table 2 shows the FORTRAN program that I used to verify the method. I took out the machine dependent portions to make the method easier to understand. For those of you not familiar with FORTRAN, the program statements that begin with C are comments and are used to explain or clarify the preceding instructions. The CALL statement tells the program to turn control over to a subroutine (a program segment that performs a task and then returns to the point after where it was called). The variable names that are in parentheses following the subroutine name are called arguments and are used to pass information from the main program and the subroutine.

The GO TO 50 statement tells the computer to take its next instruction from the statement that is labeled 50, which I did not include in this portion of the program. The string of asterisks (usually called stars because

nobody can say that other word) indicates that there is more to the program that is not included.

The SUBROUTINE statement identifies the coding to the next END statement as a subroutine with the name specified, and is completely independent of all other coding. The DIMENSION statement indicates that ICHAR and NUMBER are arrays or tables with 54 elements. The DO loop, indicated by DO 5 J=1,53, states that J is to be set to the value 1, (then) all statements up to and including the one labeled 5 are to be executed, (then) the value of J is to be increased by one and the statements are executed again and again. After the statements have been executed with the value 53 in J, then the next statement after 5 is performed. The IF statement means that if the Jth element of ICHAR is equal to I, then jump out of the loop and take the next instruction from 7. The statement between 5 and 7 insures that an ERROR character (element 54 of the tables) is used if no match causes the jump out of the loop to statement 7. Statement number 7 puts the proper value into K and the routine is finished. This is indicated to the computer by the RETURN statement. Again the END statement is used to show the limit of the subroutine.

In the subroutine MORSE the argument K is transferred into the dummy or working variable I, and is then checked to see if it is zero (indicating a blank). The next statement uses the FORTRAN-supplied function MOD that performs modular arithmetic of the first argument by the second. (It finds the remainder of I divided by 4.) I=I/4 places the quotient of I divided by 4 back into I. That sets I up for the next pass through the loop. The remainder is then check for zero, which indicates the end of the character. The keyed circuit is then turned on by the subroutine ON. The call for the subroutine WAIT demonstrates that FORTRAN allows the programmer to specify an arithmetic operation inside the argument list. In this case J is to be multiplied by M1 and the result is then used as the argument to the subroutine. The value of J (either 1 or 3) times the number of milliseconds to wait for a dit will generate the proper spacing needed. OFF is used to (what else) turn off the keyed circuit.

The coding that I show for WAIT, ON, and OFF is intended only to illustrate the actions that they perform, not how to program them. There are far too many differences in the many computers around to attempt specifying any particular routine.

As you may have guessed, this program was checked out on a large computer system. And you probably do not have a FORTRAN COMPILER on your new system. That means that you will

have to write the program for your machine, but the method will work.

Come to think of it, you don't have to have your own computer, if you have access to one. A short length of wire near the right indicator lamp or other circuit, combined with the right timing loop, will pick up an rf signal that can be used to drive a circuit. This does require two timing loops, one with rf and one without. One school in the Army uses a transistor radio set next to an IBM 1401 computer to generate its code practice tapes.

Well, I hope you have fun programming your computer. What's that? What else can you do after that? Well, I was thinking about that. Of course on-off RTTY needs only a different table. FSK RTTY? Now if you had a two tone audio frequency oscillator, you could drive that into the mike input to your SSB rig; of course, that's 100% duty cycle and you might have to modify the power level some. I was thinking that, with about eight levels of gray (I mean eight stepped tones) and that SSB audio input scheme, why, we could generate some of the fanciest computer generated SSTV signals you ever saw.

Hmmmmmmm? Receive Morse with a computer. You know, I wrote some routines for that last week. It's easier to do RTTY because the timing is all the same. Morse from an electronic keyer is not too bad, but I'm sure I found the way to copy even the poorest fist. Tonight? Aww, come on! It's 2:00 am now and I gotta catch the bus for work by seven . . . What? Sure computers can draw things on the line printer – some can give better resolution than a TV set. Record SSTV and print it out? Why not just print out QSL cards complete with addresses. Fully automated QSO? Yeah, but suppose the other guy is a computer, too? . . . ■

Inexpensive Paper Tape System

--using 5 level tape with computers

Serious program development requires the use of nonvolatile mass storage of some type. Cassette tape systems are popular among computer hobbyists, and for good reason. Cassettes are convenient, inexpensive, and provide a high density medium for mass storage. Much has appeared in the literature concerning cassette recording techniques. The use of punched paper tape for mass storage has not been adequately treated, although it is readily available to hobbyists interested in Baudot equipment. Paper tape is not nearly as fast or as dense as cassette tape, but it ranks high in convenience and reliability. Programs can be stored on individual strips of tape and labeled for later use.

The Model 19 Teletype comes with a 5 level paper tape punch and reader. The punch is mechanically linked to the keyboard, so tape must be punched by hand. The keyboard and punch can be physically removed from the printing unit and used separately. The punch magnet requires a 100 volt at 1 Amp supply. The tape reader on the Model 19 is called a Transmitter-Distributor, or "TD" for short. A punched tape is drawn through one portion at a time, and a mechanical parallel to serial conversion produces the correct teletype (TTY) signal. The tape is read at 60, 65, or 75 words per minute, as determined by a gear set inside. The TD is usually connected in series with the keyboard contacts, so that either can be used to generate TTY signals. This is a satisfactory arrangement for computer operation.

With Model 19 equipment alone, you will not be able to make paper tapes under computer control. For this capability you will need a Model 14 Typing-Reperforator. The Model 14 accepts standard Baudot TTY signals and punches a corresponding paper tape. In addition to

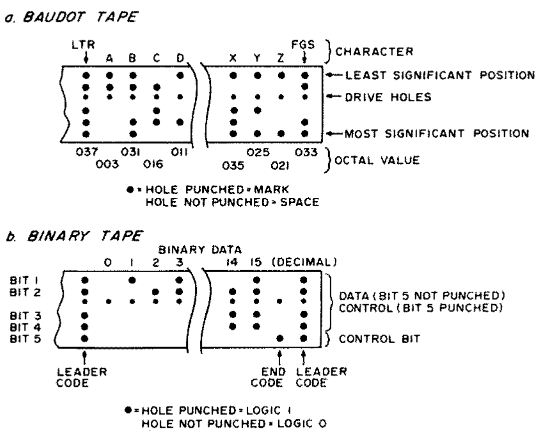

Fig. 1. (a) Conventional Baudot paper tape as used in communications service. (b) Binary paper tape for use in computer applications.

punching, it prints the incoming characters in "ticker tape" fashion. You may wonder how it prints on a tape full of holes. Nothing extraordinary here: The paper tape is chadless (that is, the holes are not punched all the way through). By the way, Model 14s come in a less expensive non-typing version, also. If you already have printer capability, this would be a good choice. Model 14s of both types are readily available on the surplus market.

The Model 14 can easily be connected into the computer I/O system. Since it accepts standard TTY signals, it may be connected in series with the selector magnets of the Model 19 printer.

Paper tapes can be punched with two basic formats: Baudot and binary. Baudot tapes record the 5 level Baudot code in five hole positions across the width of the tape. Actually, there is a sixth smaller hole (called the "sprocket" hole), but it is only used for drive purposes. With the Baudot system, a "hole" is regarded as a "mark" and a "no hole" as a "space." The orientation of the code is shown in Fig. 1. Baudot format is that used for communication purposes.

Unlike Baudot, the binary format is not in common use. In such tapes, the five hole positions are used to record 5 data bits. A "hole" represents a logic 1 and a "no hole," a logic 0. The hole position corresponding to the least significant bit is indicated in Fig. 1.

In a computer environment, Baudot paper tapes are useful for recording programs written in a high level language such as BASIC. Binary tapes, on the other hand, find greatest utility in preserving machine language programs. This is accomplished by simply punching in tape an image of the memory area containing the program. The program can later be re-entered into the same area of memory by reading the paper tape with the proper software. The discussions which follow deal primarily with punching and reading binary tapes under computer control.

The Altair 8800 and similar minicomputers have a basic word length of eight bits. Since a paper tape can record only 5 bits at a time, two read cycles are required to input the full data word. In this case, one bit of the five can be set aside for control purposes, still leaving the required eight bits with two read cycles. Bit 5 is used for the control function in our system. When bit 5 is not punched, the remaining four hole positions are considered binary data representing half of an eight bit data word. The next character in the tape without a control punch is regarded as the second half of the data word. When bit 5 is punched, the remaining four bits represent a control code. Fifteen possible codes can be used to control various aspects of the reading program. In our system, one such code is used as the leader at the beginning of the tape and another serves to indicate the end of the tape.

* TAPE READ PROGRAM
** TAPE PUNCH PROGRAM

Other uses can be made of the control code as well. Suppose you wish to send the computer a 16 bit memory address. You could prefix the four data characters with a special control code that would cause the reading program to branch to an appropriate subroutine. Table 1 gives the data and control codes both in octal and their Baudot equivalent.

As further illustration, consider the implementation of paper tape on our Altair 8800 system. A Model 19 TD is series connected with the keyboard and a Model 14 is series connected with the selector magnets of the printer. We chose two control codes: 037 octal for the leader and 020 octal for the end of the tape. As previously indicated, two character positions are required to store the contents of one memory location. The first contains the least significant four bits while the second contains the most significant four bits. If the leader is encountered within data, it is ignored. This makes it possible to correct a bad punch by simply overpunching with all holes.

The programs we use to punch and read binary paper tapes are given in Fig. 2. The punch program requires the beginning and ending addresses of the memory area that is to be stored on tape. The read program needs only the beginning address, since the end is signalled by an 020 punch.

The punch program is used in the following manner: The beginning and ending addresses to be dumped to tape are placed at 000207 and 000212, respectively; location 000170 is examined; and the RUN switch is toggled. The program generates a number of 037s for the leader. The contents of consecutive memory locations are then punched. At the end of the tape, an 020 octal is punched, followed by an additional leader. Final termination of the program occurs in a tight loop (i.e., an unconditional jump to itself). At this point, the STOP switch may be toggled.

The tape reader program is used in the following way: The address where the tape is to begin storing data is loaded at 000127; location 000123

is examined; and the RUN switch is toggled. After execution has begun, the TD is started with the tape in the beginning leader. When the program is finished, the front panel light pattern will change as a tight loop is entered. STOP may then be toggled. The program or data should be correctly stored in memory.

In the event you have a Model 19 punch and TD but not a reperforator, you can still make programs by hand. Fig. 4 is a software modification that outputs Baudot characters to the printer as they should be punched by hand. The program supplies automatic carriage returns and line feeds. A "Z" is printed at the end of each line so that SPACEs may be detected. You will note in Table 1 that data codes include CR, BLANK, and LF (line feed). These would either confuse the printout or not be printed, so the modification software makes the following substitutions:

B is printed for BLANK
L is printed for LF
X is printed for CR

Use the procedure outlined above for punching tape with the modification program loaded at 000271. The characters to be punched will be output to the printer in order. Then use the printout to hand punch the paper tape. A button on top of the punching unit can be used with the LTR key to punch all holes for error correction. When making the tape, be sure to use the LTR key to make the leader. This manual way of making a paper tape is quite tedious, but it will allow you to become familiar with the binary tape system. Fig. 4 shows a paper tape punched by the Model 14 under computer control. Also shown is the printed output of the modified punch program corresponding to the same memory data. ■

Gain for Your HT

--a half wave whip ?

After buying a two meter hand-held transceiver which came supplied with only a helically wound flexible antenna, I decided to try a full length ¼ wave antenna to see if it had any advantage compared to the "rubber ducky." A temporary ¼ wave antenna was quickly made using a 19 inch piece of wire attached to an antenna connector. Although the "rubber ducky" had performed very well, and had the advantage of being compact, the longer antenna seemed to have the advantage of greater capture area and additional height. The improvement on both receiving and transmitting was indeed noticeable.

Since better communications is the name of the game, this little experiment led me to think that if a full length ¼ wave antenna showed some improvement, then perhaps an extended length antenna would provide additional gain. Catalogs listed a wide selection of telescoping antennas for use in services outside the two meter band which could easily be modified. These come in assorted lengths and diameters, but the extremely long ones were ruled out as being unsuitable because they were too unwieldy for a hand-held set. Besides, there would be some difficulty in obtaining a good impedance match to the set.

Three of the shortest ones were selected as being best suited for modification. These had the dimensions shown in Table 1.

With the proper antenna connector (in my case an F-59), and a small loading coil to present a reasonably good match to the output of the transceiver, it is quite simple to modify any one of these antennas for two meter use. In each case a 2-1/2 inch length of 1/2 inch OD, 3/8 inch ID polystyrene tubing is used at the antenna base to enclose the coil and to insulate the antenna from the grounded shell of the connector. All coils are wound with number 20 AWG wire on a piece of plastic tubing 1-1/4" long by 5/16 inches in diameter. If soft plastic tubing is used for the coil form, the wire will hold tight and it will be easy to slip the polystyrene cover over it. For antenna A, wind 13 turns to cover the length of the form; for antenna B, wind 17 turns; and for antenna C, wind 19 turns. Spacing along the length of the coil is not critical.

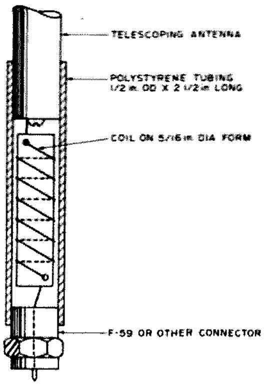

Fig. 1.

One end of the coil is attached to the base of the antenna (all telescoping antennas used came with a small machine screw in the base). The polystyrene cover is then placed over the coil so that about 3/4 inch of the antenna base is inside the cover. The coil cover is held in place with epoxy cement. When the epoxy has cured, attach the other end of the coil to the antenna connector (F-59, BNC, etc.), and cement the connector to the coil cover. Although not essential, a 3 inch length of shrink tubing placed over the coil cover and antenna base will add to the appearance and help to strengthen the polystyrene tubing.

All these extended length antennas have exhibited a remarkable improvement over the "rubber ducky," and a fair amount of gain over the ¼ wave whip. This has been most noticeable when working simplex over a range that could not be reached with the "rubber ducky" or the full length ¼ wave antenna. As I have said before, the name of the game is better communications, so anything that can be done to enhance the low power of most hand-held transceivers is well worth the effort. ■

ANT.	BASE DIAMETER	COLLAPSED LENGTH	EXTENDED LENGTH
A	3/8"	5-7/8"	43"
B	3/8"	4-5/8"	39"
C	5/16"	5-7/8'	36-1/2"

Table 1.

The Super Transmatch

--match almost anything!

73 Magazine *Staff*

The transmatch type of antenna matching network has proved to be one of the most popular designs for transmitter to transmission line coupling or for direct transmitter to antenna coupling. It will match a wide variety of load impedances, including reactive as well as resistive loads. This article describes several modifications to this network which further increase its usefulness, and various construction techniques which bypass the problems which may exist when one tries to economically purchase the components needed for the network.

Why Use a Matching Network?

Many amateurs do not use a matching network between their transmitter and antenna transmission line, particularly when feeding coaxial line from a transmitter with a pi-network output circuit. If the transmission line has an absolutely flat swr of 1:1, a matching network does not add much (e.g., to a 52 Ohm transmission line working from a transmitter output designed for 52 Ohms). The matching network, being a tuned circuit, will only add a bit more of harmonic suppression, much like a simple low pass filter. But, most transmission lines do not have absolutely flat swrs of 1:1 over the entire frequency range of an antenna. This is particularly true for thin wire dipoles or other resonant antennas used on the low frequency bands, or for the various types of trap or loaded antennas when operation over an entire amateur band is considered. It could easily happen, depending on the antenna type, that the swr is 1:1 at a particular operating frequency within a band and rise to 3:1 or 4:1 at the band edges. The result is that the transmitter will not load properly into these high swrs and reduced power output will occur.

The use of a matching network will allow the transmitter to load properly at any frequency within a band, but it will not change the swr on the transmission line. It cannot do the latter since the swr is dependent upon how closely the transmission line impedance matches the impedance at the antenna terminals. The antenna terminal impedance varies, of course, with frequency, while the transmission line impedance remains fixed. So, why bother with a matching network? Simply because the transmitter can be loaded to full power output into the transmission line. A certain percentage of the output power will still be lost due to the swr, but that percentage remains *fixed* due to the swr – and more overall power will be radiated!

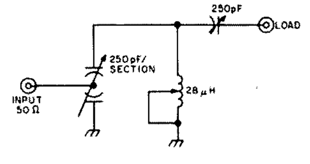

Fig. 1. Basic transmatch for 80-10 meters.

Most amateurs are still using tube-type transmitters, but it is interesting to note that as more solid state transmitters and even solid state linears appear on the market, transmitter to transmission line matching is going to become much more critical. Most solid state power amplifiers, even in the HF ranges, employ broadband interstage and output circuits. They require no tuning, but they will deliver maximum power output only when connected to a resistive load with a very low swr. Even swrs of the range of 1.5:1 or 2:1 will severely reduce power output. Since most HF antenna/transmission line setups do not provide a completely flat swr over the extremes of every band, it means that a matching network will usually be required between the transmitter and transmission line. In a sense, the tuning controls that one now associates with the output stage of a transmitter will be transferred to an external matching network.

The Basic Transmatch

The circuit of the basic transmatch is shown in Fig. 1. With the values shown, it will work from 80-10 meters and match a reasonably wide range of load impedances, be they a transmission line or an antenna directly. If a balanced transmission line or antenna is used, the output of the transmatch can be coupled to the load via a standard 1:1 or 1:4 toroid unbalanced-to-balanced transformer. The rating of the components used depends, of course, upon the power level involved, and can range from receiver-sized components for the QRP level to 3/16" spaced variable capacitors for the 2 kW PEP level. Tuning is accomplished by the use of an swr bridge between the

matching network and the transmitter. On any given operating frequency, the capacitors are tuned to establish a 1 to 1 swr with a minimum amount of inductance being used. Several settings of the capacitors and inductance can achieve a perfect match, but only the one with *minimum* use of inductance will provide a good match plus the most efficient transfer of power through the matching network. The components can be scaled down if operation over less than the 80-10 meter range is desired. For 40-10 meter operation, a 15 microhenry inductor will suffice. For 20-10 meter operation, the inductor can be 10 microhenries and each section of the capacitors need be only a 100 uF.

Circuit Variations

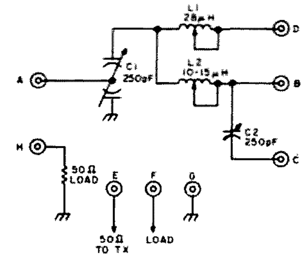
The basic transmatch circuit as described above has been in use by many amateurs for several years. However, its ability to match even a wide range of loads can be further improved and the circuit can be configured to allow the choice of several matching network forms with the same number of components or with the addition of just one more component. The modified transmatch is particularly useful for coupling to extremely short antennas or to highly reactive loads, while still retaining the use of components of reasonable size.

The modified transmatch is shown in Fig. 2. An additional inductor of 10-15 microhenries has been added and access points provided to more circuit components. Flexibility is provided by bringing the access points to binding posts and also by having the SO-239 connectors for the transmitter and transmission line (or antenna) brought to a binding post.

Jumpers between the binding posts, which can be grouped in any convenient configuration, provide interconnection. Conventional transmatch operation is provided by having the input to A, D grounded, and the load to C and L2 set for zero inductance. With very short antennas which the above configuration cannot match properly, the load is connected to B instead of C and L2 increased to provide proper loading. The network can be used as a form of pi-network by leaving D ungrounded, connecting the load to B and grounding C. Interchange of the input and output terminals (A and B) can also be tried. A conventional L matching network can also be formed. If one is working into a lower impedance than the transmitter output, C is grounded, the input goes to B and the load is connected to D. If working into a higher impedance, the input (transmitter output) goes to D and the load to B. A T matching network is formed by having A grounded, the input going to D and the load connected to B. Simple capacitive divider circuits can be formed in several ways (e.g., by grounding A, setting L1 and L2 to minimum, connecting the input to C and the load to D).

Several other circuit configurations can be arranged, and with patience just about any conceivable load can be matched. Obviously with such an array of matching circuit configurations available, it becomes important to avoid confusion. Post H provides a dummy load. The transmitter, if it has output tuning controls, is first connected to the dummy load and loaded properly. The drive can then be reduced to just enough to properly operate the swr meter connected between the transmitter and matching network. Various matching circuit configurations can then be tried, with the goal in mind to find one that provides a 1 to 1 swr and which utilizes a *minimum* amount of inductance in the matching network. This will take some patience at first (or when using a new antenna), but the settings of the components and connection points can be logged to expedite future tuning. When the transmitter drive is increased to normal level, some slight retuning of the settings of the components in the matching network will be required.

Fig. 2. Modified transmatch provides a variety of matching network configurations and greater matching range.



The Components Struggle

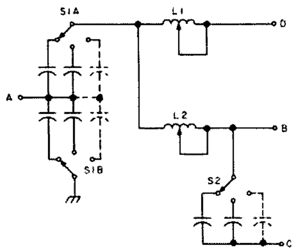
For QRP levels and powers up to about 50 Watts, regular BC type variable capacitors are usable. The inexpensive $1.29 types with teflon sheet insulation between the plates work quite well, and can be used to construct a truly compact matching network. Roller inductors are not necessary. B&W coil stock (3002 or similar) tapped every few turns can be used, or a coil can be easily home brewed using any plastic form of ½-¾" diameter and winding it with #16 wire. Handbook formulas can be used to determine the turns and spacing needed for the inductance values given. Another possibility is to wind #18 wire on an Amidon T-106, mix 2, toroid. About 40 turns are required for 28 microhenries and about 30 turns for 15 microhenries. Every few turns should be tapped. The combination of the BC variables and toroid coils makes a good combination for a QRP matching network to be housed in a very small metal or plastic enclosure, not only because of size, but because the toroids are highly self-shielding.

For the 50 to 200 Watt power level, one can, under the circumstance of not having to match extremely reactive loads, still use BC air-insulated variable capacitors and either coil stock, a home brew longitudinally wound coil, or a toroid wound coil. A suitable toroid for the latter would be Amidon T-200, mix 2, and it can be wound with #14 wire with the turns mentioned above. This would probably be the best approach to use if one were confronted with an antenna system which produces a fairly moderate matching problem (swrs in the order of 3 to 1 or 4 to 1), such as a thin wire dipole not loading properly into a transceiver over the entire limits of the 80 or 40 meter band.

However, if one wanted to have a matching network at the 50-200 Watt level which would just about load into anything going, including a 12' whip on 80 meters, a different approach has to be used. The variable capacitors should be rated at least at from 1000-1500 volt spacing. The inductors should be the roller type. Suitable such components, if purchased new, can be quite expensive. A better bet would be to find suitable components from a surplus outlet. Fair Radio Sales, for instance, frequently has available suitable capacitors and surplus roller inductors from the old ARC-5 transmitter series.

The 200 Watt-on-up power level presents a particular problem. It is difficult to believe that at this power level one would need a matching network to load into any sort of random antenna configuration. Again, for a moderate swr environment and the 1 kW power level, probably the components specified for the

Fig. 3. Fixed capacitors can replace costly variables for high power operation. See text for details.



extreme of the foregoing power level will suffice – 1000 to 1500 volt rated variable capacitors and surplus ARC-5 roller inductors. However, if one does wish to build a 2 kW level matching network that will literally load into any sort of odd antenna system, either a brute force approach can be used or a modified one. The brute force approach is rather simple. The variable capacitors should be wide-spaced and rated at 3,000 to 6,000 volts. The variable inductors should be Johnson type 229-203 or similar. The inductors are available from surplus outlets.

The capacitors present a different sort of problem. Although some 6,000 volt wide-spaced capacitors are available (from sources such as Fair Radio Sales or Barry Electronics, NYC), they are expensive ($25 range) and also consume a great deal of space. A modified approach to constructing a matching network for the 200-2000 Watt level can be used to save on capacitor costs. C1 can consist of a modest 100 pF section wide-spaced variable, as can C2. Additional capacitors can then be plugged in or switched in across C1 and C2 in 50 uF steps, so their total capacitance can be brought up to 250 uF. Note that to build up C1 only a single capacitor across it is needed, not a separate capacitor across each section of C1. Another variation of the above theme which has been tried and which does work is to eliminate the variable capacitors altogether. Plug in or switched in capacitors (5,000 volt mica types) are used as shown in Fig. 3. It would be desirable to have as many plug in capacitors as possible to simulate the variables, but one should at least have enough to form 50 uF steps up to 250 uF and one or two below 50 uF. If one knows what antennas the matching network will be used with on the various bands, a small variable can first be used, with low power, in the matching network, to establish the approximate value of the fixed capacitors for full power operation. With fixed capacitors, the variable inductors are used to tune for a match. L2 should always be used in series with C2. Probably a bit more inductance will be used than with having variable tuning capacitors. This will reduce the efficiency of the network a bit (and also, the fixed capacitors have more loss than air-spaced capacitors). With good quality components, however, and heavy strapping to interconnect components, the loss should be hardly discernible.

This article has tried to present some ideas for adding more versatility to an already good matching network. Many construction techniques are possible at the various power levels, and by careful catalog and parts box searching, one should be able to build the network economically. ■

Note: Dennis Hoffman, 1291-A Garden Terrace, Fort Dix NJ 08640, has available Johnson 28 uH kW level roller inductors at $15, and 10 uH inductors for $10 postpaid.

FCC

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20554
FCC 76-214
39630

In the Matter of Deregulation of Part 97 of the Commission's Rules to provide for greater flexibility in the administration of examinations in the international Morse code

ORDER
Adopted: March 9, 1976;
Released: March 16, 1976

By the Commission:

1. The Commission intends by this Order to allow greater flexibility in the administration of examinations in the international Morse code in the Amateur Radio Service. We are deleting that part of Section 97.29(c) of the Commission's Rules concerning the standard to be met by an applicant in the reception by ear and transmission of the international Morse code.

2. Section 97.29(c) of the Rules currently provides that in order to pass the examination in reception of the international Morse code, the applicant must copy and send one minute of plain text "at not less than the prescribed speed, free from omission or other error for a continuous period of at least 1 minute during a test period of 5 minutes . . ."

3. We believe Section 97.29(c) to be unduly restrictive. While the Commission is required by Article 41, §3 of the Radio Regulations of the International Telecommunications Union to license as amateurs only those persons proving they are able to send correctly by hand and to receive by ear texts in Morse code signals (this requirement may be waived for stations making exclusive use of frequencies 144 MHz and above), the manner in which such proof may be offered is not specified.

4. There are several alternatives to the current method of proving competency in the reception of the Morse code, and the Commission believes it to be in the public interest for it to have the option of utilizing one or more of these alternate methods. Among the possibilities we are seriously considering is a multiple choice examination covering a five minute transmission of plain text. Such a test would relieve the applicant of the extremely tedious burden of copying one minute of mixed text without error, yet would provide an accurate gauge of his competency in the reception of Morse code message content.

5. The Commission is planning to begin administration of multiple choice "message content" telegraphy examinations on a limited, trial basis in the near future in a few Commission field offices. All applicants appearing at field offices administering this type of examination will be required to undertake it. Such applicants will not be afforded the option of taking the more traditional examination. As a matter of policy during this experimental period, we will certify those applicants taking multiple choice examinations only if they have answered 80 per cent of the questions correctly. Those applicants taking the traditional examination will continue to be required to copy and send one minute of a five minute transmission perfectly in order to pass. Any change in this policy will be announced publicly in advance of the change.

6. Authority for this amendment appears in Section 4(i) and 303 of the Communications Act of 1934, as amended. Because the manner in which examinations in the Amateur Radio Service are conducted is a matter of internal agency procedure, the prior Notice and public procedure provisions of the Administrative Procedure Act, 5 U.S.C. §553(b), are not applicable.

7. Accordingly, IT IS ORDERED, that Part 97 of the Commission's Rules IS AMENDED as set forth in the attached Appendix effective March 24, 1976.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins, Secretary

APPENDIX

Part 97 of Chapter 1 of Title 47 of the Code of Federal Regulations is amended as follows:

1. §97.29(c) is amended to read as follows:
§97.29 Manner of conducting examinations.

* * * * *

(c) The code test required of an applicant for an amateur radio operator license, in accordance with the provisions of §§97.21 and 97.23 shall determine the applicant's ability to transmit by hand key (straight key or, if supplied by the applicant, any other type of hand operated key such as a semi-automatic or electronic key) and to receive by ear, in plain language, messages in the international Morse code at not less than the prescribed speed during a five minute test period. Each five characters shall be counted as one word. Each punctuation mark and numeral shall be counted as two characters.

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20554
FCC 76-228
39639

In the Matter of Amendments of Parts 2 and 91 of the Commission's Rules and Regulations to permit assignment of frequencies in the 420-450 MHz band for non-Government radiolocation.

Docket No. 20147
Report and Order
Adopted: March 10, 1976
Released: March 16, 1976

By the Commission: Commissioner Washburn absent.

1. On August 23, 1974, the Commission released a Notice of Proposed Rule Making (FCC 74-882) in the above-captioned matter proposing the allocation of frequencies in the 420-450 MHz band for non-Government radiolocation service on a secondary basis to Government and Amateur services presently operating in that band. The Notice was duly published in the Federal Register on August 29, 1974 (39 FR 31533). Comments were due by November 4, 1974, and reply comments, by November 19, 1974.

2. The proposal in the Notice was in response to the rule change as stated above, requested by Navigation Management, Inc. (NMI).[1] This request was prompted by the

SOCIAL EVENTS

from page 17

LEVELLAND TX
AUG 1

The 11th Annual Northwest Texas Emergency Net swapfest and picnic will be held in the City Park in Levelland, Texas on Sunday, August 1, 1976. Bring your own picnic basket. Free registration begins at 0900. Lunch at 1230. Swapping all day. Tables are provided. This event is for the entire family and is jointly sponsored by the Hockley County Amateur Radio Club and the Northwest Texas Emergency Net. Mobile talk-in frequency is on two meters only on 146.28-88 Mc., the Levelland Repeater: WR5AFX.

WASHINGTON MO
AUG 1

The Zero-Beaters ARC will hold their annual hamfest on Sunday, August 1, at Washington, Missouri City Park. Free parking, auction, and bingo for the XYLs. No admission fee or fee for parking in the traders row. Many prizes including station accessories, books and a handmade quilt. For info or tickets contact Al Lanwermeyer WNØQBS, or Zero-Beaters ARC, WAØFYA, Box 24, Dutzow, Mo. 63342.

MACK'S INN ID
AUG 6-8

The Wyoming - Idaho - Montana - Utah Ham Club would like to announce that the 44th Annual WIMU Hamfest will be held August 6-8 at Mack's Inn, Idaho just 20 miles west of Yellowstone National Park. There will be a full line of activities including our famous breakfast under the pines. Camping on the grounds is available plus motels, cabins and restaurants. Pre-registration is $6 per person, $1 for children under twelve. For registration or more info contact: WIMU, c/o Larry Jacobs WA7ZBO, 5655 So., 4060 West, Salt Lake City, Utah 84118.

SAUK RAPIDS MN
AUG 8

The St. Cloud Radio Club Annual Hamfest will be held on Sunday, August 8, 1976, from 10 am till closing, at the Sauk Rapids Municipal Park. Free parking and overnight parking, hot dogs and pop available. Swapfest and ham gear sale. Talk-in on 34/94 and 3925. Hope to see you all there. For further info, contact Bill Zins WAØOTO, St. Cloud Radio Club, PO Box 752, St. Cloud MN 56301.

FT. WASHINGTON
STATE PARK PA
AUG 8

The Mt. Airy VHF Radio Club (the Packrats) are holding their annual family picnic in the Flourtown Area of the Fort Washington State Park on Sunday, August 8, 1976 (rain date 15 August). Talk-in via W3CCX/3 on 52.525, 146.52, and 222.98/224.58 MHz.

PETOSKEY MI
AUG 14

Straits Area Radio Club Swap and Shop will be held August 14 from 8 am to 4 pm at Emmet County Fairgrounds on US 31, ½ mile west of southern junction of US 31 and US 131, in Petoskey, Michigan. All amateurs, CBers, SWLs, $1 admission, 50¢ per table, door prizes, lunch counter, free parking. Talk-in on 3.920 MHz, channel 1, 146.52 MHz.

LETTERS

from page 51

For three years, on Good Friday, I made the trip to the FCC office in Detroit. In the first two tests, I did not pass the code. The third time I passed the code, but was so excited about passing the 13 wpm that I messed up the sending.

Coming home a little discouraged, I realized that I had been doing a lot of other things and not really devoting enough time to my studying. I went out and bought an HW-101 because by now I was determined to get my General.

I listened to W1AW almost every night. Nights that I couldn't listen because of other commitments, I listened to code records. On April 20, 1975, I took my General Exam through the Civil Service Commission in Cleveland.

After two minutes of code copy, I could see that I had enough characters. I was so happy to have copied them, I quit copying, thinking I had enough to pass the test requirements. When I received my test results, I was disqualified for not copying for the full five minute period — but was given credit for my theory.

On June 24, I retook my 13 wpm code test and passed. After waiting four months, I called the FCC field office in Detroit and was told a four to six months' wait was not uncommon due to all the CB license applications Gettysburg has had. When six months were up, I called Detroit again. A woman gave me a Washington, D.C. number to call.

Washington told me that they had no record of my application and that it must be lost, and I would have to resubmit a new Form 610. So I got on the phone to Detroit again to get a new Form 610 sent to me. I talked to an examiner this time and he gave me the name of someone in Washington to talk with about getting special authorization to go on the air since I already had my Technician call.

I was told to send a Xerox copy of the filled out 610 which Detroit was sending me and they would see what they could do.

I sent the new application to the FCC in Detroit, and a copy to Washington, on December 23, 1975. Four weeks later, I received a temporary license good for four months; four weeks later, I received my regular General; and four and one half weeks after that, the lost license showed up (March 19, 1976) — a total of 38½ weeks and three licenses.

The second thing to go wrong happened two weeks before my license was due to arrive. I had a fellow "ham" come over to fire up my rig to see if it and my antenna system were working. Well, the rig, which had been aligned by a Heath Service Center a year before, wouldn't load up.

So, after looking at the rig for a week, I took it back to the Service Center. Seven weeks later (March 5, 1976), I got my rig back, finding out that it had a shorted capacitor in the VFO which burnt out a resistor. Total cost was $45.00 service and $.30 parts.

The third thing to go wrong, and I hope the last, happened on March 5. I had 30 feet of tower blow over, which I had only installed three days earlier (I was waiting for the weekend in order to install 20 more feet of tower with guides). One good thing was that I didn't have my 20 meter beam on it yet.

I realized that when I poured the footer, I threw pieces of broken sidewalk into the hole for fill. I had a hinge plate mounted with 9" bolts. There was also a large piece of cement just below the mounting bolts. At this point, the concrete broke and the tower came down.

That following weekend I dug a new hole and poured a new footer. This time I did not use any large pieces of old concrete and had three foot rods welded to my bolts, with cross braces welded to them.

The whole point of my letter is to encourage others not to give up, but "just hang in there." I feel that in conquering some of these "road blocks" encountered while participating in the hobby of ham radio we can learn new things, become a better person, and acquire new friendships. Also, when it is all over, we can look back and laugh at our mistakes and learn from them.

CONTESTS

from page 10

be made within two years after the contest, but not before the results are published. The fee for each certificate is DM 5 or 8 IRCs. EURO III is given for written confirmations (QSLs) from at least 20 different countries and a minimum of 100 prefix points. Countries are determined by the European countries list shown below, and each country counts only once regardless of band. Each official European prefix, however, counts one prefix point per band. EURD II is given for 150 prefix points in 30 countries and EURD I is given for 200 prefix points in 40 countries.

EUROPEAN COUNTRY LIST:

C31 - CT1 - CT2 - DL - DM - EA - EA6 - EI - F - FC - G - GC Guer - GC Jer - GD - GI - GM Shetland - GW - HA - HB9 - HB0 - HV - I - IS - IT - JW - JW Baer - JX - LA - LX - LZ - M1 - OE - OH - OH0 - OJ0 - OK - ON - OY - OZ - PA - SM - SP - SV - SV Crete - SV Rhodos - SY Athos - TA1 - TF - UA1, 3,4,5,6 - UA2 - UA Franz Josef Land - UB5 - UC2 - U05 - UN1 - UP2 - UQ2 - UR2 - YO - YU - ZA - ZB2 - 3A - 4U - 9H1.

Send application, QSLs, and fee to: DAFG, Award Manager, PO Box 1663, D — 4140 Rheinhausen, West Germany.

WORKED ALL SVARA AWARD

The Saginaw Valley Amateur Radio Association now offers the Worked All SVARA Award, which can be had by sending five QSL cards from members of SVARA and one dollar to cover the cost of printing and mailing to the Secretary of SVARA, WB8KFU, 2115 West Sloan, Burt MI 48417. The QSL cards will be returned with the certificate. Contacts must be made during 1976.

DRD AWARD

This award is offered by the DAFG to promote amateur RTTY activities and is issued each year (Jan 1st to Dec 31st). The DRD requires a total of 25 points for stations outside Germany, where each QSO with a German RTTY station counts 1 point (or 2 points on VHF/UHF). Each German station may be worked once on shortwave and once on VHF/UHF, and only 25 points per band may be claimed. No QSLs are needed. Send a summary of your log, confirmed by two radio amateurs or your radio club. The fee is DM 5 or 8 IRCs. Send application, QSLs, and fee to: DAFG e.V., Award Manager, PO Box 1663, D — 4140 Rheinhausen, West Germany.

Simple VHF Monitor

--converter for a transistor radio

This little converter, when used with an inexpensive portable transistor radio, will monitor a wide range of VHF frequencies. It can be built in a few minutes using junk box parts. Even if the parts have to be bought, they will cost only a few dollars. It doesn't provide communications receiver quality, but it is useful when tuning up a transmitter or for general coverage reception. It mounts next to the ferrite loop of the transistor radio to make up a complete receiving system. Reception over a wide range of frequencies is possible by altering the tuning coils. The components specified here cover the range of about 120 to 150 MHz. This range provides a lot of fun in listening to aircraft radio communications, the 2 meter ham band, and other services.

The circuit, Fig. 1, is that of a regenerative converter. The incoming signal, tuned by the tank coil L-1 and capacitor C-2, is mixed in the transistor with an oscillator frequency controlled by L-3 and C-7. The difference frequency is adjusted to fall in the standard broadcast band.

The converter is built on a small piece of perforated board. Parts layout is not critical. However, all leads should be kept as short as possible and the oscillator and input tank coils should be mounted at right angles to each other. The completed assembly is mounted in a small open backed metal box to minimize the effects of hand capacitance. Tuning is accomplished by drilling a ¼" hole through the box in line with the adjustment screw on the oscillator tuning capacitor. A small piece of 1/8" wooden doweling is then cemented to the tuning screw with a drop of Eastman 910 (or equivalent) cement.

A small dual gang variable capacitor could be used but would be more expensive. Tuning of the input tank circuit is very broad and does not require adjustment after it has been initially set. A hole could be drilled in line with C-2 to permit peaking, using an insulated screwdriver, after the unit is packaged. A BNC connector or RCA type female phonograph connector is mounted at the top of the box for connecting the antenna. Good reception on local signals was obtained with a piece of #14 wire 19" long for the antenna.

Coils L-2 and L-4 can be 100 microhenry VHF rf chokes, or if you don't have any in your junk box you can use TV peaking coils or simply scramble wind about 20" of fine wire on a 100k ¼ Watt resistor.

The completed converter is fastened to the back of the radio using vinyl tape or rubber bands. Placement is not critical, but try to locate coil L-3 as close to the ferrite loop as possible. I have had satisfactory results with the converter lying on the workbench a couple of inches from the radio! Connect the battery and turn the converter on. Tune the radio until a loud hissing sound is heard. Typically this will occur at at least two spots on the dial. Tune the receiver to the loudest hiss. Turn the converter power off to be sure that you are tuned to the output of the converter. Next tune in a signal with C-7 and peak C-2 for maximum signal strength.

Tuning is best done with C-7, although a certain amount of peaking can be done with the transistor radio tuning. As with most regenerative type devices, a high level signal can readily capture the tuning. Although the converter has limitations, I have had excellent reception from aircraft over 200 miles away, and from ground stations up to 30 miles away. ■

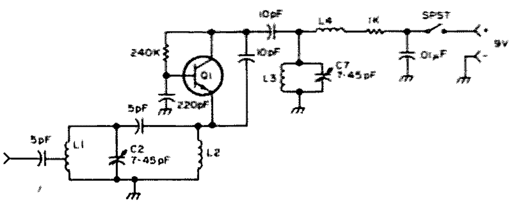

Fig. 1. Schematic of low cost VHF monitor. L-1: 4 turns #22 wire on ¼" diameter form. Center tapped. L-2, L-4: See text. L-3: 4 turns #22 wire on ¼" diameter form. Q-1: NPN VHF transistor 2N2222 or equivalent.

FCC

from page 155

termination of operation of SHORAN radiolocation systems in the 220-310 MHz range as of October 1, 1971. NMI indicated that it had developed a "second generation" SHORAN-type radiolocation system called HIRAN, which would operate in the 420-450 MHz band allocated in Region 2 to the radiolocation service preimarily and to the amateur service on a secondary basis. This band was selected by NMI because of its suitability for highly accurate medium to long range over-the-horizon radiolocation service required for mineral exploration along the outer continental shelf. NMI contended that higher radiolocation bands, such as 2900-3700 MHz, do not lend themselves to this kind of use because of their limited propagation, and sophisticated radio equipment used in SHORAN-type radiolocation systems has not been developed for operation at these higher frequencies.

3. Prior to issuance of the Commission's Notice, the US Government users who have primary status in the proposed band conducted interference tests using the HIRAN-type equipment. Based on those tests, the IRAC (Interdepartment Radio Advisory Committee) agreed to permit the proposed operation on a secondary basis to Government radiolocation services.

4. In addition, because of an urgent need for radiolocation support of oil exploration operations in Alaska, a waiver was issued on May 23, 1973, to permit non-Government radiolocation in the 420-450 MHz band in that area pending completion of the instant rulemaking proceeding. This waiver was granted on the condition that no harmful interference be caused to the Amateur Radio service, which operates in this band on a secondary basis to Government radiolocation.

5. The proposal embodied in the Commission's Notice contained restrictions similar to those stated in the waiver. The Notice stated that non-Government radiolocation systems would be permitted to operate in the contiguous 48 states and Alaska on a non-interference basis to both Government and amateur stations. Although the Commission felt there was little probability of interference from the proposed non-Government radiolocation systems, the burden would be with the operators of those systems to take corrective measures if interference did occur. Also, as proposed in the Notice, this allocation would be temporary, with a cut-off date of January 1, 1978.

6. Comments were submitted by Offshore Navigation, Inc. (ONI), American Radio Relay League (ARRL), and various amateur radio operators. Reply comments were submitted by ONI. Late comments were also submitted by Texas Instruments, Inc. (TI).

7. ONI is interested in this proceeding as a corporation rendering commercial radiodetermination services on a worldwide basis and as an entity performing research and development on the refinement of the SHORAN/HIRAN type radiolocation system. In its comments, ONI noted that the terms "SHORAN" and "HIRAN" were both used in the Notice and suggested, since HIRAN is simply a term used to identify second-generation SHORAN, that "pulse-ranging" or "SHORAN-type radiolocation systems" be the terms used in the regulations. It also commented that its experience with its HIRAN system operating on waiver in Alaska had been "most favorable." It reiterated the urgent need for radiolocation service of this type because of worldwide fuel shortages and the concomitant need for oil exploration and drilling farther and farther offshore. This need is further heightened, according to ONI, because no other radiolocation system provides the range and accuracy required for long range offshore exploration.

8. ONI's main objection concerned the proposed cut-off date for radiolocation operation in the band. According to ONI, the 2900-3700 MHz band is not a practical substitute for the 420-450 MHz band because of propagation difficulties and the consequent lack of suitable equipment. Furthermore, ONI could see no practical need for a cut-off date, as the probability of harmful interference from the radiolocation service would be very slight, and responsibility for correcting interference, should any occur, would rest with the radiolocation licensee.

9. ARRL, reflecting the views of the amateurs who filed comments in this proceeding, opposed the Commission's proposals. It pointed out the increased amateur occupancy in the 420-450 MHz band, as well as special amateur operations (for example the Oscar 7 satellite) in certain segments of the band which it felt should be protected. It stated that existing Government radiolocation operations in the band had interfered with amateurs, and that there would be a problem identifying the source of interference from non-Government radiolocation systems because of their use of pulse-type emissions. It was skeptical about the likelihood of adherence to any cut-off date once the proposed service is established in the band.

10. Various radio amateurs submitted comments, all of which objected to the proposed allocation, mainly because of

alleged problems of potential interference and the difficulty in identifying radiolocation operations which might be interfering in a particular area. The primary concern was interference to amateur repeater operations which they felt might have to be shut down *because of interference from the radiolocation* service. Several amateur operators offered suggestions to help alleviate the identification problem. One suggested that local HIRAN operations be posted at FCC field offices. Another recommended that radiolocation users be required to co-ordinate their operations with amateur frequency co-ordinators for the areas in which the radiolocation system will be used. An Amateur Radio Club in California offered to provide the facilities so an interference study could be conducted over the California coast.

11. In its reply comments, ONI stated that except for a general and unquantified reference by the ARRL, not one Amateur complained of interference from Government radiolocation stations. Furthermore, ONI cited several reasons why interference would be highly unlikely. It stated that there are thousands of miles of coastline and very limited Amateur usage of this band. Also it said that it would co-ordinate its transmitter site locations with appropriate Amateur organizations to avoid use of the channel employed by the Oscar 7 satellite. It indicated that it is also working toward minimizing the SHORAN power and bandwidth requirement.

12. TI's late comments supported the concept embodied in the rulemaking and the proposed rule change. TI explained that it too has *developed a radiolocation system* which would utilize the 420-450 MHz band in connection with geophysical exploration services offered to the oil companies. It echoed ONI's position that developing domestic petroleum resources has become an increasingly urgent matter and that the offshore area of the US offers a great untapped source. As a part of its development of this service, TI indicated that it has operated experimental radiolocation systems in several areas of the U.S. within the subject band. Its system in the Gulf Coast area of Texas has been in operation for 2 years at 430 MHz, and a more recent operation began this July in the Northeast area of the U.S., centered at 429 MHz. No harmful interference has been reported as a result of these operations.

13. The Commission is well aware of the urgency associated with this country's energy development program, in which offshore exploration plays a major role. The radiolocation services proposed by ONI and TI would appear to provide a very useful, if not essential, tool in that exploration effort. No satisfactory alternatives to either the service or frequency band proposed appear feasible within the immediately foreseeable future. Therefore, we are persuaded that some accommodation should be made for non-Government radiolocation service in the 420-450 MHz band, notwithstanding the objections raised by the radio amateurs.

14. Moreover, we believe that much of the concern expressed by the amateurs is largely without basis. There was nothing substantive in any of the comments to challenge our view, as stated in the Notice, that there would be little potential interference to amateurs from the proposed service. We still believe this to be true and further believe that making the non-Government radiolocation service secondary with regard to amateurs will provide sufficient administrative control over any interference which might occur. Any additional limitations or coordination requirements would be redundant, needlessly burdening the radiolocation service and reducing its effectiveness while providing little or no additional protection to the amateurs.

15. In addressing the comments made by the amateurs voicing their concern over potential interference from HIRAN and the consequent problem of identification, we feel that no such problem should arise because of the licensing procedure as well as the nature of the system itself. The basic HIRAN system consists of fixed units with some mobile units. The authorization is issued by the Commission for the fixed unit *at a specific location, and any time the unit* moves, a modified authorization must be issued. Therefore, complete data on each system will be on file at the Commission and will be accessible to any interested parties. Further, there will in all probability be a small number of licensees using these frequencies. The operation itself is of a highly controlled nature and handled by experienced operators.

16. Consequently, we are adopting the proposed allocation and rules essentially as set forth in the Notice. There are only two changes: (1) the term "pulse-ranging" is *being substituted for the term "HIRAN" as* suggested by ONI; and (2) the proposed "cutoff" date of January 1, 1978, for non-Government radiolocation systems in the band is being replaced by the date of January 1, 1981. We make this latter change because based on the information available tous we believe use of the 2900-3700 MHz band poses difficult technical problems for this type of application and would not offer a practical alternative to the 420-450 MHz band for at least the next five years. Also, although various satellite radiolocation systems are being developed which might *eventually be used for offshore exploration* purposes, we do not realistically foresee them becoming available for regular non-Government use in offshore areas prior to 1981.

17. Accordingly, pursuant to authority contained in Sections 4(i) and 303(r) of the Communications Act of 1934, as amended,

IT IS ORDERED that effective April 22, 1976, Parts 2 and 91 of the Commission's Rules are AMENDED as shown in the attached Appendix and that this proceeding is hereby terminated.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins, Secretary

NOTE: Rules changes herein will be covered by T.S. II(72)-9 and T.S. V(74)-3.

APPENDIX

1. In §2.106, columns 5 through 11 for the band 420-450 MHz are amended, footnote US35 is modified, and footnote US217 is added to read as follows:

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

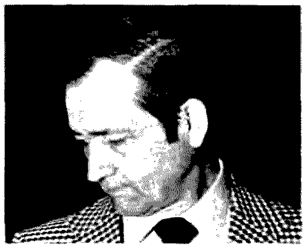
DAYTON . . . BIG

Everyone was grousing about Dayton this year, so presumably everyone was having a good time. Flea marketers lined up late Friday night to get the hot spots for Saturday . . . only to get aced out by later comers. Manufacturers arriving Thursday evening found the doors locked, and their exhibits had to be parked out overnight with fingers crossed that the usual Hamvention rip-off artists wouldn't get busy until Friday. Then there was the setting up of exhibits while being jammed with hamfesters wanting to buy stuff on Friday . . . some exhibitors never did get a chance to unpack everything!

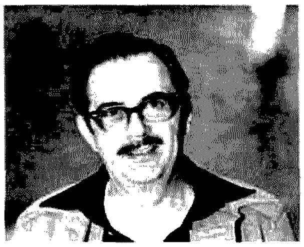
All these are things that will probably be cured next year . . . and all have little to do with the average hamfest goer . . . who had a good deal. With over 12,500 in attendance, everything was busy . . . the flea market ran out of fleas quickly and latecomers had to settle for pawing over hundreds of tons of ham gear . . . much of it choice vintage stuff. The inside exhibits wore out their people taking in the money . . . over 100 exhibits and probably an average of $20,000 taken in per booth . . . about $2 million inside and certainly not much less outside.

The talks were for the most part well attended . . . and just about everyone who is anyone in amateur radio was there. Here are some pictures of people who stopped by the *73* booth and said hello . . . people you probably know, or should.

Johnny Johnston, FCC.



Don Payne.

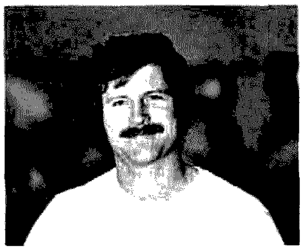


Bill DuBord, Ham Radio Center.

Bill Sanders, Data Engineering.

Clarence Munsey, Robot.

Fred Huft, Optoelectronics.



Tom Caudle, Bullet Electronics.

George Perrine, HAL Communications Corp.

IS NOVICE A KICK IN THE HEAD?

Perhaps we have become so used to starting everyone off in amateur radio with a Novice ticket that we haven't given the whole situation a lot of thought. Let's think about it together for a moment and see what comes of it.

The Novice license has a couple great benefits . . . for one it is so easy to get that it is almost ridiculous. The code can be mastered in a matter of five to ten hours . . . more like five. The theory takes about the same length of time. My code cassette teaches 75% of the users the letters and numbers of Morse code in one hour. By the way, although you do better when practicing code to keep sessions to a half hour, you do much better at first to sit for the full hour and learn all the characters . . . and one hour should about do it.

The theory required is on the high school science level and is covered totally on three one hour cassettes I've prepared. Add to that one more hour of discussing questions and answers from recent FCC Novice exams and you have a four hour course which should allow most people to pass the test easily.

Okay, so the Novice test is simple and it only takes a few days to bone up for it. The other side of the coin is what this license permits you to do.

Continued on page 14

LETTERS

BUGGED

You should tell it like it is. Re your I/O Editorial, page 81, June, 1976, *73*.

The *Bugbooks* are relatively useless unless either you purchase the kits from E&L around which they are written, or you know enough about the devices to deduce what's in the kits and start from there, in which case you probably don't need the *Bugbooks* anyway.

I know; I have the whole set and have spent a good many hours with them. I also have been in design work with TTL for some time and am studying up applications.

The *Bugbooks* don't stand alone: They need to be used with the E&L TTL kit or Micro-designer kit. There is not sufficient data to build your own kit easily, so unless you wish to purchase theirs, beware.

I will acknowledge that, if used with the E&L kits, the *Bugbooks* are probably excellent.

Joseph Naber K9AMI
Marengo IL

A very good point, Joe. I've added up the cost of the kits which go with the Bugbooks, *and they come to over $700! That puts a different light on the value of the books . . . and never mind reader complaints about the kits. — Wayne.*

MORE CARDIAC CLUES

I read in the June issue about the reader in Michigan with his pacemaker and its troubles.

My partner and I implant about 100-125 cardiac pacemakers per year. Using the Medtronic line of pacemakers exclusively, we have not had any problems with rf interference. The circuitry in the Medtronic model number 5950 demand pulse generator is such that in the presence of high rf the generator is activated rather than suppressed. On top of that, the generator is exceptionally well shielded.

Should rf activate the generator and the patient be in a paced rhythm, obviously nothing is going to happen. Should his generator be functioning in the demand mode and then be activated, he will run a competing rhythm which has some very slight danger, popularly referred to as the "one on one phenomenon," where the heart's own stimulus and the generator's stimulus fall at the same time in the cardiac cycle. The mathematical probability of this happening is extremely small, but, nevertheless, it is possible. In this rare instance it is possible to get an arrhythmia. It is also extremely unlikely that the rf field is going to be continuous for any significant period of time.

We are fortunate here in Lancaster to have a major electronics industry, the Radio Corporation of America; one of its engineers, George Gadbois W3FEY, has done considerable testing on this generator. I will ask him to comment on his thoughts and findings.

By copy of this letter, I will ask the Medtronic Corporation to voice their feelings.

In summary, I think the patient today with a good demand pulse generator has little to fear from rf, and should be permitted to enjoy the things that he is accustomed to. If there is any question, it is a very simple procedure to make a field check of an individual patient.

G. Gary Kirchner, M.D. WA3YES
Lancaster PA

BLOWING OFF STEAM

A good example of the crap that goes on when two groups of stupid people buck heads can be found in the evenings about 2100 MST most anytime that you need a laugh (or a good laxative). Just tune around 3.900-.935 kHz and listen to one group get jammed by talk, singing, tuning up, and CW on "their freq." Then this group will retaliate by turning the airwaves blue (even Nixon would blush!). The name calling, etc., is a great example of what we as communicators should not tolerate.

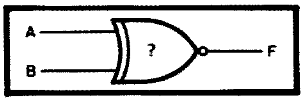
You see, CB and hams do have much in common. It doesn't pay to have such a "holier than thou" attitude such as some hams continue to have with the dirty laundry still to be washed. Of course, CB has quite a way to go yet, also. It's a shame that both couldn't work together.

Thanks for letting me blow off steam.

James L. Griffin
Seattle WA

P.S. Why do large advertisers continue to advertise rigs they do not have in stock?

Ham gear is selling extremely well these days and not much stays in stock on a dealer's shelf for long. Ads, which are expensive, are run only when the equipment has been promised by the manufacturer to back up the ads. It takes about two months for an ad to be prepared, published, and reach the reader via the mail. Many dealers have found that the promised rigs never arrive . . . that they've been sold instead to one of the larger dealers who is converting them to CB and selling them for $100 or so above list price. The promises continue, but no equipment ever comes, so money has to be refunded, a most painful process. Perhaps, if you pretend you are a CBer and pay the extra "conversion fee," you can get a ham rig. — Wayne.



A new device in the "feminine logic" family has recently become available to experimenters. It is called the "Maybe" gate, and is shown by the logic symbol above. The device functions as follows: (a) inputs 1 and/or 2 "high" may cause the output to go "high" (but maybe not); (b) if the output does go "high" it will remain "high" unless it goes "low"; (c) if the output is "high" and either input 1 or 2 goes "low," the device will probably go "low."

I'm certain you can see the potential for the "Maybe" gate in such items as "household computers," "computer-piloted automobiles," etc. A second version, with steering gates "we can't afford it" and "threats of physical violence" (on the drawing board now), should make the device more predictable.

Covina CA

COUNTERATTACK

Over the years, various state legislatures have either opposed amateur radio call plates for cars or have attempted to treat them as any other form of personalized or vanity plate — and have attempted to charge substantially extra.

For many years, California has issued call plates without extra charge. Assembly Bill 4271, recently introduced before the California Legislature, is an attempt to rewrite California laws relating to license plates. As part of this bill, amateur radio call plates would be treated as vanity plates with a $25 initial fee, $10 per year continuing extra fee and a $12 transfer charge if the plates are shifted to another car.

After talking to several local amateurs, I have agreed to coordinate, at least for Southern California, a counterattack in an attempt to prove to the Department of Motor Vehicles and the State Legislature that call plates serve a valid purpose and should not be lumped in with vanity, personalized plates.

The first step in the counterattack will be to gather information from amateurs throughout the country, and not just in California, as to as many specific instances as possible where callsign plates have assisted amateurs in performing a public service function. These instances could range from occurrences in which an individual needing emergency communications has stopped a ham because he has ham radio plates and has asked that message traffic be passed, through facilitating participation in community activities or entering into closed areas during emergencies for the purpose of handling authorized emergency traffic. I do wish to stress that I need hard information as to actual instances in which call plates have been helpful, as opposed to mere statements of opinion.

Not only will this information be utilized to oppose the pending California legislation, but I will be happy to make the information available to attorneys and radio clubs throughout the country that may have to oppose similar anti-call plate legislation in their states.

Any publicity which you could give this effort would be appreciated.

All information should be sent to Jon Gallo WA6PTM, Suite 2000, 1900 Avenue of the Stars, Los Angeles CA 90067.

FIGHTING DIABETES

It was certainly a great pleasure meeting and speaking with Wayne at the Trenton State College Computer Fair. I have been reading *73* for about 2 years now, and enjoy it immensely.

At Trenton, I heard comments concerning *73*'s proliferation of microprocessor articles. I have to comment that I cannot agree with those who feel that microprocessors have no place in an amateur radio magazine. Well, contrary to this popular belief, most of the *real* applications for the microprocessor have come from hams. Hams have accessed computers via satellite. Hams are using computers as tools around the shack, for keeping logs, keeping track of equipment, controlling antennas, and for scoring and duping during contests. The list could continue *ad infinitum*.

As it stands, most avid amateur computerists have been able to use their machinery for such mammoth tasks as playing the game of Life or Star Trek — great fun, but isn't a kilobuck awfully expensive for a game?

Granted, computers are and should be fun, but don't you agree that each of us should have *one* serious application in mind for these tools *before* we dedicate them to games?

I am a diabetic of 24 years, on insulin from the onset of my condition at age 4. My 21 month old

daughter is also diabetic. I have an idea that could well benefit her and all other diabetics, provided that it gets the developmental support that it deserves. My theory is that the new electronic marvel, the microprocessor, provides us with the extremely accurate basis needed for an artificial pancreas.

Although slow by the standards of the huge electronic brains, the microprocessor is quite fast enough to take the digitally coded output from an analog device that would constantly test blood glucose levels. This would be compared by the processor against a pre-established glucose level for the individual patient. The digital result would then be used to establish the need for insulin, as well as determine the dosage required. This digital figure would then be used to control the analog amount of insulin administered.

This would have been impossible 6 months ago, but the state of the art in microprocessor technology has advanced so rapidly that such a device, with all of its speed and accuracy, should be available to the diabetic within the year, for less than $100.00.

I will be working on such a theory, developing whatever portions of such a unit that I can, with the hope of presenting this theory at the Personal Computing '76 Consumer Trade Fair (Atlantic City NJ, Aug. 28-29, 1976), so that its development can be advanced by the experts of the microprocessor field who will be in attendance at this show. My hope is that some of the expertise used to develop such games as Life and Star Trek can be enlisted in the development of something that will serve, rather than only amuse, mankind.

ALL IS NOT ROSES

All is not roses in the mail order business. We, like every other reputable mail order house, try to satisfy our customers to the best of our ability. However, there are many pitfalls to scuttle our endeavors. The customer can help a great deal just by doing things such as making sure his address (and name) are on his order blank or letter – as well as on the envelope. (If one Peter C. Johnson would send his address along to us we would be happy to reply to his request for our catalog.) Another important thing is to *type* or *print*. So far we've managed to decipher all orders, but it has not been easy. Oh yes – don't forget your check or money order.

Not having a crystal ball, we cannot predict what items will be selling the most. In April it was 2N6081s – it seemed every order was for them. We did run out, and of course it took us six weeks to get our order from the factory. If we do run out, we try to get word to our customers that we'll be late. We would appreciate their understanding of this problem.

Last but not least is our great mail service. A lost package sent out and a lost letter stating the package wasn't received garnered us a letter of complaint from one state's Attorney General. We used to worry about how long it took a package to get to a destination (and most of our stuff goes out First Class) – now we worry about whether it will arrive at all.

But on top of it all we're still going to hang in there.

Lynbrook NY

VERY SMART

I got some issues of *73 Magazine* and I like them very much. I am not a ham operator but a ham DXer. I do shortwave listening as a hobby. I enjoy listening to ham operators. They are very smart at the hobby. I don't understand a thing they talk about.

I am going to try my hand at ham radio and get my Novice license. I am so thankful for other ham operators who can help me. They are all so willing to give me their time and help. I am greatful to Dudley WA3JXW, who got me interested in ham radio by sending me a radiogram. He is trying to find a class for me so I can learn code and theory. It will take me a long time before I get on the air. So until I get on the air I will say "73" to all ham operators.

Larry McKinney

Adamstown PA 19501

GOOD WORK

Keep up the good work on computer theory and construction.

T. D. Miller III W4SWB
Burlington NC

ANYONE FOR DVORAK?

I have a suggestion for you (and especially your readers) to consider: I would like to see an idea swapping feature each month.

Every one of your readers has creative talent and I think that it should be shared. Maybe someone has a neat idea for a piece of equipment or a plan for using a different mode. Perhaps they have thought up a useful computer program or fun game, but they don't have the computer to run it. Maybe they just aren't any good at building things and they would like to pass the idea along to someone else.

The thing that would probably be the best feature of such a idea swap would be idea hitchhiking. The actual suggestions might not work out, but they might start someone else thinking about how to make it work.

I have seen plenty of idea generation material in the "Letters" column, and I've only had a subscription for five months. I think that ideas, even half baked ones, should be encouraged. The world and ham radio needs creative thinking.

Also, I have an idea that I would like to see passed along to microprocessor and RTTY enthusiasts (keyboard Morse types as well). The "standard" typewriter keyboard is an awkward, difficult thing to learn and use. It was developed over a half a century ago to *slow down* the typist, because the early typewriters were slow, cumbersome pieces of machinery that jammed up if the typist had even moderate skill. In the early '30s, A. Dvorak developed a keyboard that doubled the average person's typing speed and reduced learning time, as well as reduced fatigue and frustration for the beginner. The concept was to put the most used keys on the "home" row of keys, put the most used keys under the strongest fingers, and put the vowels together. The last was done because most words alternate between vowels and consonants, which leads to alternate hand rhythm.

It seems to me that if you are building or working with a keyboard that you can re-wire, the Dvorak system is worth considering.

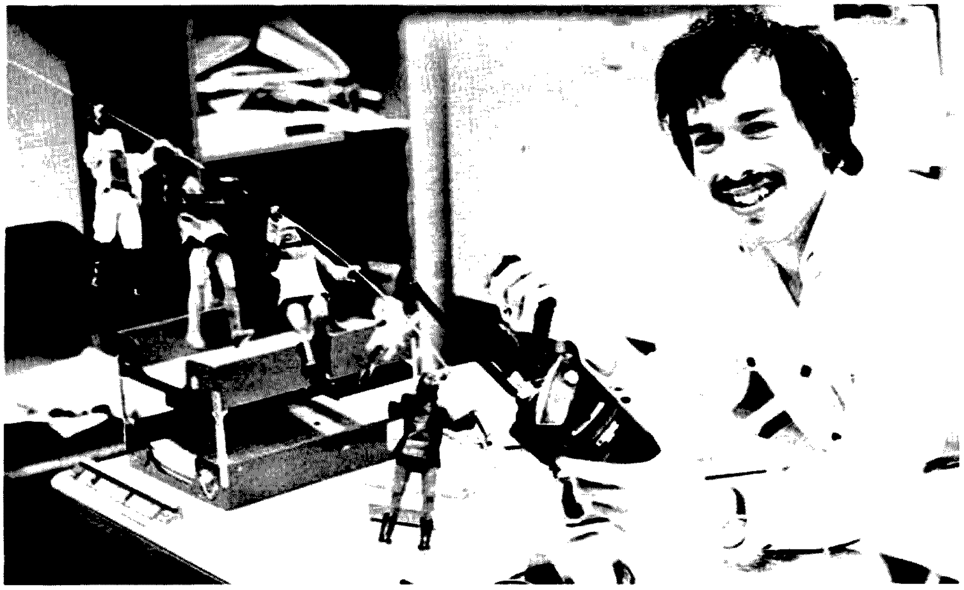
ANOTHER SHOOTING VICTIM

I received my first copy of *73* for May and I sure do like it. But it sure upset me about one thing. That is about Trigger Electronics, with which Larry S. Lawhorn WA4MJA had trouble. I myself ordered $47.20 of amateur gear from them on April 6th and sent a cashier's check by bank draft. I have written them once and



called them long distance twice. I have not got the order or my money. I am trying my best to get it and if I don't I want all hams and *73* to know it also. I have been a ham since 1961 and would not do any of my fellow hams that way. I want to warn all fellow hams. I will let you know the results. I am retired and Social Security is my only income and I cannot afford many losses like this. Keep up the good work. I look forward to the next issue.

Horace M. Lewey, Sr. WA4CUD
Greensboro NC

WHAT DOES THIS MEAN?

I have received on this day, the third of May, all at the same time, *73 Magazine* for June, 1976, *QST* for May, 1976, and *CQ* for April, 1976. What does all this mean? Cheers!

Paul G. Stecker
Westwood NJ

THICK IRISH SKULL

Your *73* article ("Those Exciting Memory Chips," June, page 96) was very good. I'm trying to get some of this new solid state down, but my thick Irish skull can't seem to absorb it. Anyway, thanks for the fine article.

Jim Sullivan W1PSW
Woburn MA

BICENTENNIAL PLATES

The Missouri Department of Revenue will honor all requests for bicentennial call letter plates. All requests must be written and should contain the applicant's name, address, type of vehicle, current call letters, bicentennial call letters which they are requesting, and must be received before July 1, 1976. The requests should be mailed to the Motor Vehicle Bureau, Box 100, Jefferson City MO 65101, Attention: Special License Unit. The fee for all Amateur Radio plates, regular or bicentennial, is an additional $5.00 over the normal cost of license plates.

C. A. Jurgens, Jr. WAØCMO
Jefferson City MO

LITTLE PARIS

This is a report on the operation of FKØKG, a YASME DXpedition to Noumea, New Caledonia.

The first QSO was with JA1AB on 30 March 1976, and the last QSO was with FG7AQ on 28 April 1976. Some 7,500 QSOs were made, operating on 28 MHz, 21 MHz, 14 MHz, 7 MHz and 3.5 MHz. Operation on all bands was made on both CW and SSB (approx. 50% each mode).

On 16 April 1976, all continents (WAC) were worked on 7 MHz CW in two hours and 5 minutes. QSOs were F9YZ (0605 Z), K6HMO (0608 Z), ZL2AMP (0625 Z), PY1ARS/4 (0630 Z), EA8BF (0808 Z), and JA1ABU (0809 Z).

We were amazed to discover Noumea to be the largest and most modern town that we have visited in the Pacific Ocean areas (excluding Honolulu). It is a "little Paris," with many beautiful homes, apartment buildings, modern department stores, traffic jams, etc. Some of the local city buses have true hi-fi stereo sound on them for the enjoyment of the passengers. Speakers on one side of the bus are on one channel and speakers on the other side are on another channel. The only problem with Noumea is that everyone speaks *French*. We know a little French but could have enjoyed the city more if our French was better.

The taking of radio gear in and out of New Caledonia was easy, and our licenses to operate were obtained rapidly. All in all, it was a great place for a DXpedition. We had a good time, and band conditions, although erratic, were good.

Lloyd Colvin W6KG
Iris Colvin W6DOD
Noumea, New Caledonia

COLOMBIAN MOONBOUNCE

The Mount Airy VHF Radio Club (The Pack Rats) is pleased to announce that it has received permission from the Colombian Minister of Communications to conduct a moonbounce experiment from South America on 432 MHz.

As of April 27, no South American continent stations had been available for 432 MHz EME work. The station will be located near Barranquilla and will be operated by S. William Olson W3HQT, Walter Bolman K3BPP, and Anthony Souza W3HMU. Arrangements for the trip are being made by Bolmar Aguilar WB3AOP, Elliott Weisman K3JJZ, and Socrates Martinez WB3AFY.

Colombian liaison is being handled by Dr. Atenogenes Blanco HK1BYM, who has coordinated a group of radio amateurs in Colombia representing all of the active radio clubs in Barranquilla (HK1RCB, HK1EE, HK1LR). Dr. Blanco's address is Apartado Aereo 15-020, Barranquilla, Colombia, South America.

Operation will be on 432.040 MHz, using a portable 16 yagi array especially constructed for this project. Liaison during the South American operation will be maintained with Pack Rat stations stateside. Those wishing to convey information to the expeditionary force should contact Ernie Kenas W3KKN or Bertha Kenas W3TNP, 2823 Old Welsh Road, Willow Grove PA 19090, (215)-659-3485.

Communications with the expeditionary force in Colombia may be obtained via Dr. Blanco, whose address is listed above.

It is our intent to work as many of the 432 moonbounce stations as possible from this location, and schedules have been made with all of the 432 EME stations known to be active at this time. Anyone requiring additional information with regard to the expedition may contact me.

ALL-STAR ALTAJ

I recently placed an order with Altaj Electronics, for the miserly sum of $3.79. Although Altaj is Texas-based, and I live in Mass., I received the order (in perfect condition) in less than five full days. Furthermore, the shipping cost, for which Altaj picked up the full tab, came to $1.40.

I wonder if all of your readers are aware of the fact that this outfit has no minimum order, and absolutely does not charge for postage or handling.

Malcolm Leonard
New Bedford MA

LIKE IT!

Received my MAY issue of *73* today in *March* — uh, but, you see, er — that is to say, uh, how — I've *never* — *no one* — er, not even — no! it's just *not* — uh, especially since — and then too, there's, uh — son of a gun! Great! F.B. articles, too! Like it!

Bud Resch WØFTD

VERADA 214

I feel I should write you in regard to one of your advertisers in *73*.

In April I saw an ad from Verada 214 and ordered an amplifier from there. It was to be complete with face plate and knobs. The order came by mail (postpaid) in less than a week. Really pleased me with their prompt service. But, it was missing the knobs. A little disappointment, but knobs are cheap, no sweat. Tuesday of the next week, before I had a chance to either rewrite them or buy knobs, another package comes from Verada 214: not only the knobs for the tuner, but a short note from J. Rutherford, apologizing for the mistake.

I certainly would recommend them to any of your readers. Add Verada 214 to the long list of people that are F.B.

Thanks for a fine mag (lifetime subscriber to *73*), and for your dedication to allowing only reliable companies to place ads in your mag.

Harry Mitchell WB2SFZ
Baldwinsville NY

DOWN UNDER

Just a little note to let you know about VHF activity in VK. Plenty of FM activity — repeaters in all capital cities and big towns. Mostly commercial gear — ICOM 22s, TR10s, etc. The advent of the YAESU 620 and 220 VHF SSB gear has given it a big boost. Since the commencement of the year, the new ICOM IC-202 and IC-502 low power portable 6 and 2m SSB gear has made VHF even more popular. Some surprising QSOs over amazing distances with the little units. Everyone is making solid state linears run 10 W and 40 W PEP. OSCAR 6 and OSCAR 7 are accessible with the units and the linears and a moderate beam. ZLs and P29s are some of the DX.

S. J. Mahony VK5ZIM
Elizabeth Downs

DIGESTING

After the customary six week incubation period following each and every subscription application, I received the May '76 copy of *73* and have spent about a month memorizing every page. This done, I eagerly anticipated the next month's copy. Yesterday I received the April '76 copy, which I am likewise digesting, and I'm sure I will be equally anxious for the March '76 copy. Keep up the good work!

Lyle Ross W5UPD
Richardson TX

P.S. Please don't bother to send the January '76 issue because a fellow ham who received six copies gave one to me.

Ham Help

I need Ham Help!

Keep up the very good work on your magazine. It's the best in my book. Love everything in the issues, even the advertising.

Would like to get in touch with someone owning a Kenwood TS-511S transceiver. I have been on the air for a year now and still haven't heard anyone with this kind of set. Would like to compare notes and iron out a few problems I have with the set. Thank you.

Leo Patin WB9PCO

Oconomowoc WI 53066

SPEEDY SERVICE

Just a few words along with my Reader Service requests to say that your code tapes are great! I just listened to the five words per minute tape every now and then, and after a couple of weeks I had passed my Novice code test with ease. I'm now awaiting my Novice license, and looking forward to getting on the air.

Gary E. Szatkowski
Sault Ste. Marie MI

P.S. I also compliment your Reader Service and its speedy replies — and the overall magazine. Keep it up!

WHY NOT?

I hereby submit my first letter to your honorable publication, which I was introduced to by Ken Cole W7IDF, and have anxiously awaited receipt of each and every month.

Just read your May letters column, and agree with Steve Uhrig WA3SWS. How about a "White House" type article on *73*, Inc.? We *must know* what the people who run the magazine look, act, and operate like. Pictures, especially, would help. Let's hear it . . . and see it!

Excellent magazine you've got there, and keep up the good work, including subversive activities in an attempt to overthrow the ARRL regime, if that's what you're after. F.B.

As a CBer and ham, I can appreciate all of what both titles stand for. Being KDZ-9707 has its advantages over WN7AVF, and vice versa. Personally, I think the CB situation is and/or will get better. 10-4?

More basic logic articles like you had last year. F.B. on your new I/O section. Only wish I could afford a microprocessor.

New format is good. All good things must come to an end, and the old minisize did. Big size offers more room, detail, and ease of reading. I give my full approval.

Before you get too carried away with this computer bit, as I said before, include more basic explanations for us Novices and equally uninformed Extras, if there are any.

Have one of your tapes, the 14 per one. Will say I listened a *total of 3 hours* to be able to pass the General. Great tape(s) . . . used it twice, since I failed the written part the first time. F.B.

Have been receiving *QST*, and your magazine is far more interesting, informative, humorous, etc. Speaking of humor, why not put in a few cartoons with a technical or ham-political theme? We need a laugh in these times of trouble, etc., etc., etc. Your editorials are also very good, and I also like the "Autobiography of an Ancient Aviator."

Let's have lots of ATV, repeater stuff, HF-CW, SSB, SSTV, and computers and computer technology. You'll undoubtedly kill *HR, CQ, QST*, or anybody else, with a lot of new, bright stuff.

As for increasing membership (in ham radio), CB offers the ideal source.

There's hope for "conversion." Amen. Ham conventions and hamfests should be open to CBers, without any ill feelings (or at least just a grit-your-teeth smile). Here CBers could become interested and could be welcomed by hamdom. Of course, generally (in the real world), they would not be welcomed, but they could be. Why not????

Robert B. Barnard WN7AVF
Seattle WA

MORE MAPLE HILLERS

WB2YCR, the radio voice of Maple Hill High School, Castleton, New York, is proud to announce the licensing of four new amateur radio operators. The four young men recently completed an intense six week course taught by WA2UON at Maple Hill, and successfully completed FCC tests showing both their ability to send and receive the international Morse code and their mastery of basic radio theory and regulations.

The new radio men are: Al Ferreira WN2EQP, Geoff Schad WN2EQN, Robert Porter WN2EQO, and Scott VanNederynen WN2EQQ. All four are part of the Maple Hill High School Amateur Radio Club (WB2YCR) and are also members of the high school's audio-visual special team, "The Media Men."

John Kienzle WA2UON
Castleton NY

NEVER MATCH 2M FM

I have been buying your great magazine, and this was the deciding factor which has made me start learning that famous Morse code.

I plan to get the General license during the month of September. Hopefully, before this year is over I will be on the air.

I am a computer programming major at Florida International University, and I think that your computer section is great — but please don't cut the amount of articles and construction projects about 2 meter FM.

Keep up the good work.

Rene A. Nunez
Miami FL

P.S. I have a CB license, even if I don't have a transceiver right now. On the road it's a great help, but it will never be able to match 2m FM.

VENEZUELAN INDEPENDENCE CONTEST

Phone
Starts: 0000 GMT July 3
Ends: 2400 GMT July 4
CW
Starts: 0000 GMT July 31
Ends: 2400 GMT August 1

Contacts with stations in the same country are permitted on all bands for country multiplier credit, but have zero point value. There are 4 classes of competition:

Single operator — single band; Single operator — all bands; Single transmitter — multi-operator; Multi-transmitter — multi-operator (only 1 xmtr per band).

Use all bands 80 to 10 meters.

EXCHANGE:
RS(T) and progressive QSO number starting with 001.

SCORING:
QSOs with stations in different country count 2 points, while with stations in same country count zero points. Venezuelan stations may, however, contact each other on 40 and 80 meters for 1 point per QSO but will score zero points for contacts with other YVs on 10, 15, and 20 meters. The final score is the total QSO points multiplied by the sum of YV zone call areas and countries on each band.

AWARDS:
A trophy will be awarded to first place in each category. Medals will be given to the highest scoring station in: N. America, Central America, S. America, Caribbean, Europe, Asia, Oceania, and SWLs. No station can be awarded more than once! Certificates will be issued to all stations having made the following contacts: Caribbean and N., Central, and S. America (except YV) — 20 YVs plus 10 different countries for SSB and 15 YVs plus 10 different countries for CW; Europe and Africa — 10 YVs and 10 different countries; Asia and Oceania — 5 YVs and 10 different countries; YV stations only — 30 YVs on 40 and 80 mtrs, 10 different countries (including YV), and 50 QSOs with foreign stations *for SSB; On CW* — 15 YVs on any band plus 10 different countries (including YV), and 50 QSOs with foreign stations; SWLs — 50 complete QSOs, including a minimum of 10 YVs. Both exchanged numbers must be shown in the log for credit. Medal to the SWL with the maximum QSOs.

ENTRIES:
Each entry must be accompanied by a summary sheet showing all scoring information, category of competition, mode, name, callsign, address in *block letters*, and a signed declaration that all contest rules and regulations for amateur radio in the country have been observed. A remittance of S2 or equivalent IRCs is requested with each entry to cover awards and handling. All entries must be postmarked no later than Sept. 15, 1976, for the phone section and October 15, 1976, for the CW section. SWL deadline is December 15, 1976. Mail logs to: Radio Club Venezolano, P.O. Box 2285, Caracas 101, Venezuela. Logs must show all times in GMT. Indicate YV zone call area and country multiplier only the first time it is worked on each band. *Use a separate sheet for each band!*

VK7 USA BICENTENNIAL CONTEST

Starts: 1400 GMT, Saturday, July 3
Ends: 1400 GMT, Sunday, July 4

RULES:
There will be two sections to the contest: a) single band, transmitting open (single operator); b) multiband, transmitting open (single operator). All U.S.A. and VK7 amateurs may enter the contest, whether their stations are fixed, portable or mobile. Amateurs may use all modes, and crossmode contacts are permitted. All amateur bands may be used, but crossband contacts are not permitted. Skeds for other bands are allowed.

SCORING:
VK7 stations: 1 point per contact per band and, in addition, 5 bonus points for each new state worked on each band. U.S.A. stations: 1 point for the first contact, 2 points for the second, 3 points for the third, etc. A station may be contacted once only per band for scoring purposes.

NUMBERS:
Before points may be claimed for a contact, numbers must be exchanged and acknowledged. The number will be made up of RS (phone) or RST (CW) reports, plus the year in which the operator first received his license. U.S.A. stations must also give the state they are in.

LOGS:
Logs must show date and time in GMT, band, callsign of station contacted, number sent, number received, and score. VK7 stations must also underline and show each new state worked.

SUMMARY SHEET:
Summary sheet must show callsign, name and address (in block letters), details of equipment and power used, whether single or multiband log (entry), and score.

ENTRIES:
All logs should be sent to: The Contest Manager, P.O. Box 1010 Launceston, Tasmania 7250, Australia. They must be in the hands of the contest manager before 1 November 1976.

ARRL BICENTENNIAL CELEBRATION

Starts: 0000 GMT Saturday, July 24
Ends: 2359 GMT Sunday, July 25

Object of the contest is for US stations to work as many stations as possible, while non-US stations will try to work as many US stations as possible. US to US contacts are permitted. US entries must be single operator while non-US entries may be either single or multi-operator. Multi-transmitter, however, is not permitted. No more than 36 hours of the contest period may be operated, with time-outs not less than 15 minutes long and no more than 8 time-outs total. Each station may be worked once on voice and once on any other mode. No repeater contacts, except through OSCAR, are allowed. A station may not be worked with a regular call followed by a contact with a bicentennial call; only one contact per mode.

EXCHANGE:
US stations send RS(T), state, and state entry number into the Union (see list below). Non-US stations send RS(T) and consecutive serial number starting with 001.

SCORING:
Simple: Final score equals number of QSOs; *no multipliers.*

AWARDS:
US stations: 1776 or more QSOs, 200 or more QSOs, 50 or more QSOs on or above 50 MHz, ARRL section high score, WAS, 200 or more QSOs with non-US stations. Non-US stations: 1776 or more QSOs, 200 or more QSOs, 50 or more QSOs on or above 50 MHz, country high score, WAS, and worked 13 original colonies.

ENTRIES:
A summary sheet, log sheets, and check sheets are required from all US entries. Summary sheet and log sheets required from all non-US entries.

Special summary and log sheets will be available from ARRL headquarters if an SASE is enclosed. Entries must be postmarked no later than September 1st. Send all requests for logs and all entries to: ARRL, 225 Main Street, Newington CT 06111.

ORDER OF STATE ENTRY INTO UNION:

1 – CT – 5, ME – 23, MA – 6, NH – 9, RI – 13, VT – 14; 2 – NJ – 3, NY – 11; 3 – DE – 1, MD – 7, PA – 2; 4 – AL – 22, FL – 27, GA – 4, KY – 15, NC – 12, SC – 8, TN – 16, VA – 10; 5 – AR – 25, LA – 18, MS – 20, NM – 47, OK – 46, TX – 28; 6 – CA – 31, HI – 50; 7 – AK – 49, AZ – 48, ID – 43, MT – 41, NV – 36, OR – 33, UT – 45, WA – 42; 8 – MI – 26, OH – 17, WV – 35; 9 – IL – 21, IN – 19, WI – 30; 0 – CO – 38, IA – 29, KS – 34, MN – 32, MO – 24, NE – 37, ND – 39, SD – 40, WY – 44.

RESULTS

Results of the 10-10 International Net of Southern California, Inc. Annual Winter QSO Party

The two top scorers in each district were:

K1KYC	221/522
WA1STR	215/507
K9EGA/2	292/723
K2ARO	198/532
WA3VQF	214/531

New South (Ga.)	43/98
Red River Valley (La.)	35/95

10-10 NET SUMMER QSO PARTY

Starts: 0000 GMT Saturday, August 7
Ends: 2400 GMT Sunday, August 8

All contacts must be made on 10 meters, any mode. Participation by non-members is welcomed but they are not eligible for awards. To become a member and receive a number, send a list of 10 members worked (DX work 5) and $3.00 to the manager in your district (DX to W6LRY).

EXCHANGE:
Name, QTH, and 10-10 number and chapter.

SCORING:
Members score 1 point for each contact and add 1 point if with another member (maximum of 2 points per QSO).

AWARDS:
First and second place certificates to each US district, Hawaii and Alaska, each VE province, S. Amer., Central America and Caribbean, Europe, Africa and South Atlantic, Asia and N. Pacific, Australia, New Zealand and S. Pacific.

ENTRIES:
Logs must include date/time, station, name, QTH, and 10-10 number. Members only should send logs to: Grace Dunlap K5MRU, Box 13, Rand CO 80473, postmarked no later than Sept 30th. Results will be listed in the Winter Bulletin (from 10-10).

EUROPEAN DX CONTESTS
CW – PHONE – RTTY

CW
Starts: 0000 GMT August 14
Ends: 2400 GMT August 15

Phone
Starts: 0000 GMT Sept 11
Ends: 2400 GMT Sept 12

RTTY
Starts: 0000 GMT Nov 13
Ends: 2400 GMT Nov 14

Only 36 hours of operation out of the possible 48 are permitted for single operator stations. The 12 hours of non-operation may be taken in one to three periods anytime during the contest. All bands, 80 to 10 meters, may be used on the specified mode. Classifications include: single operator-all band, and multi-operator-single transmitter. Each station may be worked once per band. A contest QSO can only be established between a non-European and a European station. In the RTTY section only, contacts with one's own continent are permitted and will count 1 point per QSO. Multipliers will be counted as described below.

EXCHANGE:
RS(T) and progressive QSO number starting with 001.

SCORING:
Each QSO counts 1 point. Each confirmed QTC (given or received) counts 1 point (see below) but only 10 QTCs to the same station on all bands together are allowed. The multiplier for non-EUR stations is the number of EUROPEAN countries worked on each band. Europeans will use the ARRL country list. In addition each call area in the following countries will be considered a multiplier: JA, PY, VE, VO, VK, W/K, ZL, ZS, UA9 and UAØ. Each multiplier may be multiplied by the following factor depending on the band: on 80 meters, multiplier times 4; on 40 meters, multiplier times 3; on 20, 15, 10 meters, multiplier times 2. The final score is the total QSO points plus QTC points multiplied by the sum total of multipliers from all bands.

QTC TRAFFIC:
Additional point credit can be included by utilizing QTC traffic. A QTC is a report of a confirmed QSO that has taken place earlier in the contest and later sent back to a EUR station. It can only be sent from a non-EUR station to a EUR station, the general idea being that after a number of EUR stations have been worked, a list of these stations can be reported back during a QSO with another station. An additional 1 point credit can be claimed for each station reported. Each QTC must contain the time, call and QSO number of the station being reported and can be reported only once (but not back to the originating station). You may work the same station several times, with a maximum of 10 QTCs to that station, but the original contact is the only QSO with QSO point value.

AWARDS:
Certificates to the highest scorer in each classification in each country, reasonable scores provided. Continental leaders will be honored. Certificates will also be given to stations with at least half the score of the continental leader. Additional certificates and plaques will also be awarded. The minimum requirements for the awarding of certificates and trophies are 100 QSOs or 10,000 points.

ENTRIES:
It is suggested that the log sheets of the DARC or equivalent be used. Send a large size SASE for logs and summary sheets. Use a separate log for each band. Violation of the rules of this contest, unsportsmanlike conduct, or taking credit for excessive duplicate contacts will be deemed sufficient cause to disqualify. The decisions of the Contest Committee are final. Mailing deadlines for entries are: CW – September 15; Phone – October 15; RTTY – December 1. Mail entries to: WAEDC – Committee, D-895 Kaufbeuren, Postbox 262, Germany. North American residents may send entries to: H. E. Weiss WA3KWD, 762 Church Street, Millersburg PA 17061.

EUROPEAN COUNTRY LIST:
C31 – CT1 – CT2 – DL – DM – EA – EA6 – EI – F – FC – G – GC Guer – GC – Jer – GD – GI – GM – GM Shetland – GW – HA – HB9 – HBØ – HV – I – IS – IT – JW Bear – JW – JX – LA – LX – LZ – M1 – OE – OH – OHØ – OJØ – OK – ON – OY – OZ – PA – SM – SP – SV – SC Crete – SV Rhodes – SV Athos – TA1 – TF – UA1346 – UA2 – UB5 – UC2 – UN1 – UO5 – UP2 – UQ2 – UR2 – UA Franz Josef Land – YO – ZA – ZB2 – 3A – 4U1 – 9H1.

SARTG WORLDWIDE RTTY CONTEST

Contest Periods:
0000 to 0800 GMT Saturday, August 21
1600 to 2400 GMT Saturday, August 21
0800 to 1600 GMT Sunday, August 22

The 6th WW RTTY Contest is again sponsored by the Scandinavian Amateur Radio Teletype Group. Use all bands, 80 to 10 meters.

CLASSES:
Single operator up to 100 Watts input; single operator over 100 Watts input; multi-operator single transmitter (any power); SWLs.
EXCHANGE:
RS(T) and QSO number.
SCORING:
QSO points as follows: own country = 5 points; other country in same continent = 10 points; other continent = 15 points. In USA, Canada, and Australia, each call district will be considered as a separate country. The same station may be worked once on each band but only RTTY QSOs count. Final score is total QSO points times the number of different ARRL countries and W, VE, and VK call districts on each band. SWLs use the same rules for scoring based on stations and messages copied.

AWARDS:
Awards will be issued to the top stations in each class, country, W, VE, and VK call district.

ENTRIES:
Mailing deadline is Sept 18, 1976. Logs must contain: band, date and time in GMT, callsigns, exchanges sent and received, points, and multipliers. Use a separate sheet for each band and enclose a summary sheet showing the scoring, classification, your call, name and address. Comments will be very much appreciated. Send your log to: SARTG Contest and Award Manager, C. J. Jensen OZ2CJ, Meisnersgade 5, 8900 Randers, Denmark.

RESULTS

Results of 8th Giant RTTY Flash Contest
The top 10 scorers of the 51 entries:

Call	*Score*
I1BYS	13,379.542
K4GMH	8,528.384
W3EKT	8,933.145
DLØTD	5,128.512
WA2JVB	3,879.288
G3VXO	3,663.900
I6NO	2,898.135
WAØYDJ/4	2,502.162
SMØOS	2,086.080
K7BV	1,986.944

The 1975 RTTY Championship was won by I1BYS with 120 points, while W3EKT finished second.

NEW JERSEY QSO PARTY

Contest Periods:
2000 GMT Saturday, August 21 to 0700 GMT Sunday, August 22
1300 GMT Sunday, August 22 to 0200 GMT Monday, August 23

The 17th annual NJ QSO Party is again sponsored by the Englewood ARA. Phone and CW are considered the same contest. Each station may be contacted once on each band, and phone and CW are considered separate bands. Duplicate QSOs may not be made using bicentennial calls! NJ stations may work other NJ stations. General call is: "CQ New Jersey" on phone or "CQ NJ" on CW. NJ stations are requested to identify themselves by signing "DE NJ" on CW or "New Jersey calling" on phone. Stations planning active participation in NJ are requested to advise the EARA by August 7th, so that full coverage from all counties may be planned. Portable and mobile operation is encouraged.
FREQUENCIES:
1810, 3535, 3905, 7035, 7135, 7235, 14035, 14280, 21100, 21355, 28600, 50-50.5, 144-146. Suggest phone activity on even hours; 15 mtrs on odd hours (1500 to 2100 GMT); 160 meters at 0500 GMT.
EXCHANGE:
QSO number, RS(T), and QTH – ARRL section or country. NJ stations will send county for their QTH.
SCORING:
Non-NJ stations multiply total number of QSOs times number of NJ counties worked (21 max.). NJ stations: W and VE QSOs count 1 point; DX stations count 3 points. Multiply total number of QSO points times number of ARRL sections (including NNJ and SNJ – 75 max.). KP4, KH6, KL7, KZ5, etc., count as both 3 point DX contacts and as section multipliers.
AWARDS:
Certificates will be awarded to the first place station in each NJ county, ARRL section, and country. In addition, second place certificates will be awarded when 4 or more logs are received. Novice and Technician certificates will also be awarded.
ENTRIES:
Logs must show GMT date and time, band, and mode, and be received not later than September 18, 1976. The first QSO for each claimed multiplier should be indicated and numbered, and a checklist of contacts and multipliers should be included. Multi-operator stations should be noted and calls of participating operators listed. Logs and comments should be sent to: Englewood Amateur Radio Assoc., Inc., 303 Tenafly Road, Englewood NJ 07631. A #10 size SASE should be included for results.

ARIZONA QSO PARTY

Starts: 1700 GMT Saturday, August 28
Ends: 1700 GMT Sunday, August 29

The full 24 hour contest period may be worked. All stations are eligible to enter. Out-of-state stations work AZ stations; AZ stations work all stations. Stations may be worked on both phone and CW once per band on 80 to 10 meters. All stations are encouraged to use bicentennial callsigns.
EXCHANGE:
RS(T) and QTH; AZ county for AZ stations; state or country for non-AZ stations.
SCORING:
All stations score 1 point per SSB QSO, 2 points per CW QSO, and 4 points per Novice QSO. There are 2 scoring categories for AZ stations: single and multi-op. AZ stations operating outside their home county receive a bonus of 50 SSB QSO points. AZ stations multiply QSO points (plus any bonus) by the number of states/VE provinces/DX countries worked. Non-AZ stations multiply total QSO points by the total number of AZ counties worked on each band (14 max.).
FREQUENCIES:
Phone – 3935, 7235, 14285, 21360, 28575; CW – 3560, 7060, 14060, 21060, 28060; Novice – 3725, 7125, 21125, 28125.
AWARDS:
Certificates will be awarded to the top 3 AZ stations and to the top station in each state/VE province/DX country. A minimum of 5 QSOs is required to be eligible for an award. Include a description of all equipment used and the usual signed contest declaration. Include a legal size SASE for a copy of the results and any award. All logs must be postmarked on or before Sept. 30, 1976. Send all entries to: Motorola Amateur Radio Club, 8201 E. McDowell Rd., Scottsdale AZ 85252.

ALL ASIAN DX CONTEST
CW

Starts: 1000 GMT August 28
Ends: 1600 GMT August 30

All amateur bands under 30 MHz may be used with power, mode and frequencies as permitted by station license. No crossband contacts are allowed. Entry classifications are: single operator-single band (each band), single operator-multiband, and multi-operator multiband. Single operator entries cannot have more than one signal on the air at a time, while multi-operator stations cannot have more than one signal on each band at a time. General call is "CQ AA" for non-Asians and "CQ TEST" for Asians. Non-Asian stations contact only Asian stations.
EXCHANGE:
For OM stations: RS(T) and 2 digits indicating operator's age. For YL stations: RS(T) and ØØ.
SCORING FOR NON-ASIAN STATIONS:
Count 1 point per Asian contact. Multiplier is number of different Asian prefixes worked on each band. Contacts with KA stations are not eligible, since they are considered military stations and not amateur stations. Final score is sum of QSO points times the sum of the multipliers on each band.
AWARDS:
Various awards will be awarded the highest scorers in each category in each country and US call area, depending on the number of entries.
ENTRIES:
Submit a copy of your logs and a summary sheet no later than November 30, 1976, to: JARL, P.O. Box 377, Tokyo Central, Japan. Logs must show date and time in GMT, station worked, report sent and received, multipliers and points. Use a separate log for each band and include your callsign. Summary sheet should show name of contest, entry classification, callsign, operator class, country, address and name, site of station if mobile or portable, station details, comments, and signed declaration. Also, include a table showing number of QSOs, points and multipliers per band. At the bottom of the table show totals along with final score. Violation of the contest rules, false statement in report, or taking credit for excessive duplicate contacts may be cause for disqualification. Results will be announced about April, 1977. Include one IRC and an SASE with your logs to receive a copy of the results.
COUNTRIES LIST OF ASIA: A4, A51, A6, A7, A9, AP, BV, BY, CR9, EP, HL/HM, HS, HZ/7Z, JA/JE/JF/JG/JH/JI/JJ/JR, JD1 (Ogasawara Is.), JT, JY, OD5, S21, TA, UA/UK/UV/UW9-Ø, UD6/UK6C,D,K, UF6/UK6F,O,Q,V, UG6/UK6G, UH8/UK8H, UI8/UK8A-G,I,L,O,T-Z, UJ8/UK8J,R, UL7/UK7, UM8/UK8M,N, VS6, VS9M/8Q6, VU, VU (Andaman and Nicobar Is.), VU (Laccadive Is.), XU, XV, XW8, XZ, YA, YI, YK, ZC4/5B4, 1S (Spratly Is.), 4S7, 4W, 4X/4Z, 7O (S. Temen), 7O (Kamaran Is.), 8Z4, 9K2, 9M2 (W. Malaysia), 9N1, 9V1 (Singapore), (AbuAil).

TU-BORO FAST SCAN ATV CONTEST

On October 3, 1976, the Tu-Boro Radio Club will sponsor a fast scan ATV contest on 439.25 MHz. Any station working three or more Tu-Boro members will receive a certificate suitable for framing. Stations currently active on ATV who are Tu-Boro members are WB2TCC, W2LXC, WA2WAK, WB2KEK, W2JNU, and WA2NXB. All correspondence should go to: Tu-Boro Radio Club, 149-14 14th Avenue, Whitestone NY 11357. The time of the contest is from 9:00 am to 11:00 pm.

EDITORIAL BY WAYNE GREEN

from page 4

The fact is that it will permit you to get on the air . . . with low power . . . in a crowded band . . . using code only . . . usually with poor equipment which even an expert would quickly throw aside. No wonder such a small percentage of Novices stick it out.

Like it or not, darned few people get into amateur radio with the idea of making CW contacts. They want to talk on phone and they deeply resent CW as an abomination jammed down their throats. I suspect we would have ten times as many CW ops . . . and happy ones . . . if CW were optional, not required by law.

So what do I suggest? Well, when us doddering oldsters got into hamming, we started right out with 13-per and our first ticket permitted phone operation. We made it all okay and the percentage of increase of hams was better than it is today with the Novice starter system. I propose that a few clubs stop trying to con people into that Novice business and get them immediately into a General Class license. It'll take a little bit longer, but I think we'll have a lot more hams as a result.

How much longer will it take? I'd sure appreciate it if a few clubs would run some tests with their classes. I suspect that it won't take a lot longer to learn the code at 13 words per minute than 5. That seems impossible? Well, please remember that most people have been learning the code the worst possible way for many years . . . starting off slowly and then relearning it again and again one speed after another . . . each time having to train their brain to recognize the different sound patterns. The *73* code cassettes start right out with each character at 13 words per minute, right from the first introductory tape. From there it is not much more difficult to go immediately to the 13 per tape than it is to the 6 words per minute tape . . . each has all characters sent at 13 wpm.

Several fellows came up to me at Dayton and said that they had tried going directly to 13 per and had found little problem with it. They said that they had found it startling at first to only recognize a few characters, but that the rest of them quickly clicked into place, and before they knew it they were copying at 13 per. The *73* tape is so merciless that they could copy straight text at 15 per with solid copy . . . and the FCC 13 wpm test sounded slow to them.

How about it fellows . . . let's try some General classes for beginners and see what happens . . . if it works we might just dump that Novice ticket entirely. I think we'll get a lot more enthusiastic hams out of it.

BETTER OPERATING

An article was submitted recently which made fun of the ham operator who makes long and repetitive transmissions. Talk about shooting fish in a rain barrel!

Since I don't think that making fun of the mentally retarded is fair game, I returned the article . . . but not without wishing that someone would come up with some good ideas on how to improve the quality of the average ham contact. As a major offender in this matter, I think I can speak with authority.

When I'm trying to drive and talk over the radio at the same time, both suffer . . . a lot. I don't think I'm unusual in this, judging from what I hear coming through over the repeaters. My friends credit me with being a wit . . . my detractors give me at least half that much credit . . . so when my wits (what there are of them) are further split by the demands of trying to control my car careening down the road, watch for fuzz, keep one ear on the CB for Smokey reports, and not totally ignore my passenger, I end up with a hemi-demi-semi-wit on the repeater. I am not alone.

Let's do what we can, in spite of the odds outlined above, to encourage better operating. In particular, there are four things that we can try and watch for in our own transmissions: excessive repetition, trite phrases, ham language, and an obvious lack of anything whatsoever to say.

Excessive repetition encompasses such boring things as repeating anything twice when you know your signal is solid copy. You know how you hate it when someone keeps telling you he is going to sign off. Take a big clue from the CBers on this one . . . when they say they are gone, they are really gone. Some ham contacts go through a dozen or more final transmissions.

There are a few ops who are unable to call a spade a spade . . . they have to call it a digging implement. They don't go to the doctor, but to the sawbones. They modulate the mattress, see you down the log (what log?), and in general speak a very weird language, little of which is clever or original. Many of us get into the habit of using ham terms a lot more than is necessary, forgetting that there may be a bunch of non-hams listening to us who perhaps don't know our codes. It is not much more difficult to say we are going to change channels than to say we are going to QSY. Or that we are going to shut down instead of QRT . . . etc. You get the picture.

A little listening to the CB channels may convince you of the sterling qualities of the English language. You have to learn a whole new vocabulary to talk CB . . . kind of like learning Swahili (and not much more difficult). The CB Swahili is just an exaggeration of the bad habits we've gotten into on amateur radio.

Just a thought.

CLUB PROGRAM

One of the most important factors in holding a ham club together is an interesting program. Experienced club officers know that one of the surest ways to kill off a club is to permit business meetings to take up too much of the meeting time . . . members get all wrapped up in the hassle over whether to paint the clubhouse or not, but somehow they forget to come to meetings after that. Club members want to be entertained, and if you don't provide the entertainment, television will.

A talk by a manufacturer on his ham product is one of the best drawing cards for club programs. Unfortunately, these chaps are spread out all over the country, and there are seldom more than one or two available in any one area, so clubs quickly run out of ham-oriented speakers.

In order to make talks by ham manufacturers available to clubs and thus perk up the club programs, I am going to get them to put their talks on tape and I will send you a cassette tape of their talks. Once I get this thing going, I hope to have one or two half hour tapes available every month . . . and at no cost to you. The manufacturer is trying to sell you his products, so we'll let him foot the bill.

It is terribly difficult to get much information about new products. The ads don't tell very much . . . and neither do most of the product reviews. The one person who really knows the product is the manufacturer, and he is obviously the one we want to hear talk about his product. I will caution him that self-serving puffery will be transparent, and that if he really wants to get our confidence he'd better level with us. Since we can logically expect more than a little bias I suspect that a clever manufacturer will bend over backwards to make sure his talk has credibility.

If your club would like to get these tapes, all you have to do is get your secretary to send a card or letter letting me know how often you meet (like monthly), approximately how many attend meetings (in case there are flyers to go with the talks), the name of the club, and the address to which to send the cassettes and flyers (if any). You might let me know if you would prefer one half hour talk or two. Send that to *73* Club Programs, Peterborough NH 03458.

A CB AD IN 73? WHAT NEXT?

There are a lot of good reasons why every one of us should be active on CB these days, and darned few good reasons for avoiding CB. Yes, I know all about the bad language, the terrible things that have happened on CB . . . but I also know that much of that is past history. Another thing I know is that our own hands are not clean . . . we've had a bunch of the foulest language you can imagine jamming some of our service nets and locking up some of our repeaters. No, we can't come on as Mister Clean. You should see the mail I've gotten regarding the Eddy Palmer situation down in Tennessee!

We amateurs can do a lot of public service via our two meter repeaters and service nets, but by hooking into the biggest net of them all – CB – we have even more ears. I, for one, like to know where Smokey is lurking, but even without that benefit I wouldn't be without CB these days. Once you get off the truckers' (19) channel you can get into interesting and intelligent (at times) conversations with people who talk English. And if there are any road problems ahead, you will know about them in plenty of time to take evasive maneuvers. I managed to find a back way into a shopping center just before Christmas when the main roads leading into it were backed up for miles. I've avoided a lot of traffic snarls and accident scenes by keeping my CB set on channel 19. I've reported local accidents to the police via CB which otherwise I would have had to call in via long distance through repeaters.

But perhaps most important of all, I have a lot of fun telling CBers about amateur radio. I start talking with them as I drive along and soon they want me to stop and show them an HT with a touchtone pad on it or my two meter FM radio. They get all dazed at the ranges we consider normal on two meters, and when I tune in some DX for them on 20m they are almost stupified. Few of the really active CBers refuse to take the bait. They want to know about hamming; most of them have heard about it and they really want to know. Tell them. Get them into your club classes. You can't hook 'em if you aren't on there.

There are a lot of good CB rigs on the market and there are some real dogs. We're busy testing out as many as we can get here at *73* so we can let you know which seem to be okay. The other day, when I was visiting the FCC in Washington, they had just completed some tests of CB rigs in their labs and they were astounded at how dirty some of them were . . . putting out crud over a wide range of frequencies. I think you'll see some action from the FCC on this before long.

The CB gang almost got a bunch of extra channels. It was all set to go through. As I understand it, someone up at E. F. Johnson had his thinking cap on and wondered what would happen if two mobile rigs were on at the same time in close proximity and 455 kHz apart . . . wouldn't this raise

hell with the broadcast i-f channels of AM radios and CB sets? A few tests showed that this was indeed true, and the okaying of the band expansion was halted at the last minute, probably staving off a disaster of enormous proportions. We think we have intermod problems on two meters!

If any readers have good factual data on which CB rigs are the best, we're interested . . . write an article. We don't want to turn even a part of *73* into a CB magazine, but since hams are looked upon as communications experts, we do have a responsibility to let you know what is what. I don't want you to be in the position I was in the other day when a chap wandered into the *73* offices and wanted to know where he could find out what CB rig was good. I thought it over for a while and had to admit that I had no answer for him. The CB magazines are no help. Neither are any books I've seen. Hmmm. Let's get that info out where it can do some good.

NEW MAGAZINE SIZE BOOMERANGS

Let's take a short trip back through memory lane . . . just a year ago when *QST* announced the new size magazine which would save thousands of dollars in publishing costs. My answer was baloney — a larger magazine takes more paper and that means more cost. I wrote this at the time and got a lot of flack from brainwashed ARRL members who believed *QST*.

So here we are a year later and the proof is there for anyone who *can* see to see. *QST* has met the increased costs in two ways. One, they've shrunk considerably in the number of pages . . . it was 34% thicker last year. Secondly, they've gone from about 30% ads to 50% advertising! Last year they had 85% more pages devoted to other than advertising . . . 130 pages last year to about 70 this year!

When costs go up, a magazine has to either raise advertising rates or else run a higher percentage of advertising. *QST* has done *both*. The costs of publishing *73* have gone up with the increase in size, just as I said they would . . . from about $36,000 per month last year to $56,000 a month this year. We've increased our ad rates and kept the percentage of advertising unchanged from last year.

I predicted that the costs of publishing the ham magazines would go up and that it would be the readers who would pay . . . through higher prices for ham gear which would result from the higher ad rates. Just you watch the prices of ham gear this summer and fall and then tell me that I was wrong. I hate being wrong.

MAKE A BUNDLE

How would you like to make $50 to $300 a month for a couple days of work? With the increased interest in amateur radio and *73 Magazine* resulting from the CB explosion, there is a big need for *73* to be distributed on the newsstands. If you would like to become a *73* regional newsstand distributor you might be able to make a nice extra bit of money.

Distribution in the newsstand field is set up with regional wholesalers, each of which services a hundred or so newsstands. These chaps handle so many magazines that most of them don't want to be bothered with a new one . . . particularly one of such esoteric interest as *73*. They prefer to deal exclusively with national distributors so they get their magazines in large bunches and have just one set of forms to fill out for a large number of magazines.

After trying two different national distributors and finding ourselves fairly well convinced that this was a bad way to do business, we have cancelled our national distribution sales contracts and are working via local wholesalers exclusively.

If you would like to be considered as a local wholesaler, please drop our Marketing Manager Sherry Smythe a note and tell her what area you want to cover, how many newsstands you would service, and about how many copies you would like to start with. You only have to pay for sold copies, so you can't lose.

How do the economics work? You buy copies for 75¢ each and sell them to the newsstands for $1.00. They sell them for $1.50, making a 50% profit. You make 25¢ for each copy sold. Thus you make $25 for each hundred copies sold in your area. You have to go around once a month and deliver the new issues, pick up the unsold issues, and collect for those sold. It's fun and it's profitable. And who knows, once you have the route set up and your contacts, you might want to try handling a few more magazines . . . at least until your spare time is used up. The deliveries can be made evenings and Saturdays . . . records can be kept evenings. And who couldn't use a few hundred extra dollars a month?

Write Sherry Smythe, *73 Magazine*, Peterborough NH 03458.

WRITE AND GET RICH!

For years I've been bumbling along, vaguely aware of a problem, but not coming up with a solution. Now I think I've got a splendid plan which will help everyone involved.

The other day I was talking with a manufacturer. He was griping because I ran a picture of a competing product as an illustration in an article. What made the situation really bad for him was that we were running his ads and not those of the competitor. He was aggrieved . . . and I would have been too were I in his shoes.

My suggestion was that instead of hassling me about it, he should make sure that I had plenty of photos of his products on hand. I reminded him that I had visited his plant and asked that he send pictures for just this use, but had not yet gotten anything. I further pointed out that since his product was a most interesting one, he could do a lot worse than have a writer prepare an article or even a series of articles about the products he was making. These articles should discuss the design philosophy, the uses, the benefits to the user . . . and in general tell everything possible about the product.

The manufacturer liked the idea, but said he had no one on his staff who could write these articles . . . and didn't even know anyone who could do the job . . . who would I suggest? I pulled a name out of the hat and he is going to contact the writer. Hopefully the result will be a very interesting series of articles . . . absolutely pure gold sales literature in reprints . . . and a writer who has made a big bundle writing on contract for the firm.

Though I have more than enough to do without getting into the manufacturer-writer marriage business, I will be glad to help writers contact firms who need material prepared. And vice versa.

There is no question that such articles are wanted . . . every time I do get one, the reader response is most gratifying. The big problem is getting the articles written.

If you are a *73* writer you might take a good look at any relatively new piece of equipment you've been using and get in touch with the manufacturer to see if he might be interested in underwriting an article on the unit for submission to *73*. I don't guarantee publication, naturally, but you know that I am hot for such material and if it is at all usable you won't be able to keep me from grabbing it.

One word of warning to both writers and manufacturers . . . no one truly believes that any equipment is perfect, so be sure to emphasize the good points and mention the drawbacks . . . it will make for a lot more reader credibility and, in the end, result in a lot more sales.

There is a great temptation to try and shush problems . . . like the early Clegg miseries with LEDs burning out. They burnt out one right after the other, and after a few days you couldn't tell what frequency was being read out. Sure, they solved the problem . . . but they missed a lot of PR and attention by not making a big deal out of the problem and the solution.

I think that a good writer could make a lot of money writing for the manufacturers. A big firm should be able to pay $500 to $1000 for a good article, and a writer can easily turn out a dozen of those a year in his spare time. Even at today's inflated costs that is a nice bit of change.

The field is not restricted to ham gear either . . . I know that I'm interested in material on equipment of interest to the ham, the experimenter, the computer hobbyist, and even the CBer. We've got some CB plans ahead and want to get ready for that, whether it be a series of books or a magazine.

FCC'S 5 WPM!

I've mentioned this before, but a lot of amateurs have missed it . . . and a letter from a reader in Kentucky brought it to mind . . . when you go to the FCC to take a 5 wpm test you'd better be able to copy each character at 13 wpm with the spacing between characters at 5 wpm. This is the way you are taught on the *73* code tapes, by the way, so if you find yourself called down to the candy factory for a retest, get hot with the #6 cassette.

THAT FEBRUARY COVER

Here's a picture of a Star Trek communicator as built by Ron Dodge WB0IHR of St. Paul MN and on demo by Jane Skeil. Ron and Jane were using it to beam down to the Dayton Hamvention (photo by W2NSD/8).

New Products

YAESU FT–221
2M TRANSCEIVER
Fred Goldstein WA1WDS

What's more fun than a barrel of crystals, more powerful than a smoking HT, more useful than a box of 6146s, and has a handle? If you're interested in getting on two meters in style, the Yaesu FT-221 will fill the bill handily.

The FT-221 has complete band coverage, VFO or crystal-controlled, on FM, SSB, CW and even AM. Output on SSB is 20 W PEP; on FM and CW it's 10-14 W. It's easy to operate, since all circuits are either internally compensated by the band switch or broadbanded. Full output is thus achieved across the whole band, which is tuned as eight 500 kHz segments.

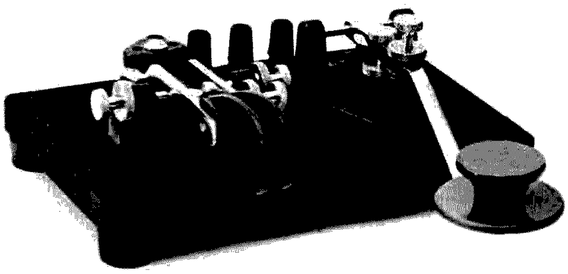
Until you try it, you might think eight band segments is too many. But virtually all SSB is within 25 kHz or so of 144.110 and 145.025, except for the OSCAR segment. Repeaters are tuned only from 146.5 to 147.5, so you can switch from 146.79 to 147.30 without having to tune the dial more than 10 kHz. 600 kHz offset is automatically provided on those two segments. A reverse switch inverts the operation, for California plan split-splits or just working inverted on a repeater pair. That's the best tool for catching Touchtone Tommies if you have a beam.

Among the other handy features are the front panel mike gain control and the built-in tone burst. Construction is modular, using computer cards that come out for repair or maintenance. The internal adjustments are right on top of the cards, for easy access. And the dial drive is a smooth dual-speed unit.

The circuitry shows that good engineering went into the rig. The receiver uses an FET preamp and mixer, feeding a 10.7 MHz crystal filter. For SSB, a noise blanking gate (very effective if you operate SSB mobile) precedes a sharp lattice filter and the i-f strip. The FM i-f is separate, using a second conversion to 455 kHz and a Murata F filter. Selectivity is excellent. The s-meter is fixed to the SSB i-f, so a carrier reading indicates that you're tuned into the repeater. The meter can also be switched into a center-tune position. On transmit, it indicates relative output.

Local injection is provided via a phase locked loop that mixes the crystal band segment oscillator with the VFO or channel crystal (8 MHz). The VFO is not multiplied, so there is very little drift. The PLL keeps the spurs and images down better than a bandpass mixer.

The result of all this circuitry is top performance. The receiver hears only what it's supposed to hear, and hears it well. The transmitter sounds fine. Most 2 meter radios are prone to intermod, so I took the FT-221 to the top of Pack Monadnock – a heavy duty rf zone. While the Brand X radio in the car was deluged by garbage all over the band, the Yaesu was clean as a whistle. I had a nice chat on SSB with a station in New Jersey, which gave me an S9 report. Not bad for twenty Watts and a five element hilltopper beam. Unfortunately, there's not much SSB activity yet up here in the sticks, so it helps to make skeds. But that should change soon as more people discover that SSB is at least as good on VHF as it is on the "dc bands" – especially with radios as good as the FT-221.



STRAIGHT KEY OR DUAL LEVER PADDLE?

The choice is yours with Ham Radio Center's Model HK4. Here's a double threat with both weight enough to stay put and velvet smooth action. All plastic parts are of high impact styrene, and the red plastic and black crackle finish really catch the eye. The color-coded binding posts make the unit idiot-proof. It's a joy to operate, with provision on the paddle for wide or close finger spacing. At $44.95, delivered, it's indeed that rarity in today's market – a bargain. *Ham Radio Center, Box 28271, St. Louis, MO 63132.*

STANDARD HORIZON 29
(see page 65)
Wayne Green W2NSD/1

Normally I wouldn't rush into *73 Magazine* with a big write-up on a new CB rig . . . but these are not normal times.

It should come as no great surprise to *73* readers that I've been active on CB for a couple of years now . . . even to the extent of getting a license, so you *know* I must be quite active! During all this time I've been using a very well-known brand of CB rig . . . one with an excellent reputation.

One of the bigger favors done to me recently was the theft of this fine rig. I came back from the computer convention in Albuquerque to find my car at the Boston airport sitting unlocked and my CB rig missing. Thank heavens I'd removed the IC-230 before parking! My stereo tape deck was still there . . . just the CB gone. Zounds! That'll teach me not to have an alarm on my car. I don't need it up in New Hampshire, but down in Boston is something else.

The old rig was a beaut . . . but the noise generated by my car . . . Datsun 280Z . . . was beyond belief and limited my reception to about a mile under good conditions. I found that when I wanted to hear much further than that, I had to speed up the car, turn off the engine, cut off the squelch, and turn up the volume control. Then, when the car slowed down enough to cause a traffic backup, I had to stop trying to hear and turn back the volume, turn up the squelch, and settle for local signals again. You wouldn't believe what a royal pain it was to try and find out about traffic conditions under those restrictions.

Then along came the Standard Horizon 29 rig . . . magically it fit right into the bracket still left hanging under the dash. Between the automatic noise limiter and the noise blanker, my threshing machine car noise was so gentled that I could hear the weak ones out for miles! It brought new life to old Snidely Whiplash, I'll tell you.

And you know how crumby some of the CB rigs sound? Well, I've listened on the other end to my Horizon 29 and it sounds as clear and crisp as you could ask . . . beautiful. It has a gain control built right into the microphone.

The public address part of the unit puts out 10 Watts, enough to be heard by motorists in front of you if you have any well-chosen comments to make . . . perhaps to warn them of a dangling exhaust system, burnt out lights, flat tires . . . or perhaps a helpful comment on their driving skills. It also allows you to monitor your CB when you are out of the car.

The Horizon 29 has one other feature you don't usually find on the smaller CB rigs . . . a clarifier tuning control. This will permit you to tune in any slightly off channel signals and bring them in clearly. It won't help off color channels. This only moves the received frequency, not the transmitter.

While many CB units still use crystals for frequency generation, the Horizon 29 is digitally synthesized, using a phased lock loop (now don't you wish you'd read the articles on PLL?).

About the only serious problem with CB these days is the tendency to get hung up on it and the fun of talking briefly with passing motorists. The other night I was perking along the Connecticut Turnpike, keeping one ear on CB for traffic warnings and having a very pleasant contact over a local 2m repeater when someone came on the channel and was extremely abusive . . . fortunately he didn't identify himself. I retreated to CB and struck up a conversation with someone somewhere ahead of me who was into car rallies. I didn't get back on 2m for an hour . . . and well out of range of WA1ABR.

CB isn't hamming, for the most part . . . it's different . . . and I wouldn't be without either service. I do manage to get in a lot of PR for hamming with CBers . . . because they are interested. Millions of people are just discovering two-way radio and the possibilities for fun it holds . . . the more we can encourage them, the better.

One more thing. While the Horizon 29 allows me to hear a lot further than before, I still have a lot of garbage generated by the 280Z. I'd sure appreciate hearing from anyone who has been able to clean up one of these mobile noise generators.

NEW MACHINE LANGUAGE MANUAL

Scelbi Computer Consulting, Inc., Milford CT, has just published and released a detailed new manual, *Machine Language Programming for the "8008" and Similar Microcomputers.*

According to the authors, this text is an easy-to-read, 170-page basic manual needed to develop today's machine language programs. The illustrated manual covers such areas as a detailed presentation of "8008" codes, flow charts, mapping, a floating-point package, and basic programs, including loops, counters and masks.

Further, there are sections on multiple-precision arithmetic, debugging, organizing tables, editing and assembling, mathematical operations, I/O, real-time programming, maximizing memories plus more. It has been said that the floating-point arithmetic package is worth the price of the manual alone.

Copies of *Machine Language Programming for the "8008" and Similar Microcomputers* are available by sending \$19.95 ppd (foreign orders, add \$6.00), or using Master Charge, to Scelbi Computer Consulting, Inc., 1322 Rear Boston Post Road, Milford CT 06460.

ALPHANUMERIC TRANSFER SHEET

There is no longer any pen and ink work needed to produce sharp component identifications. Now you can just rub off the designations you need from Trumbull's alphanumeric transfer sheet.

There is no need to hunt from sheet to sheet to match up an alpha designation with a numeric designation. All commonly used components are printed arranged in a/n series (R1, R2, R3 . . . R51, C1, C2, C3 . . . C30, etc.).

Multiple series of each of the above designations are available in each set. Lesser used designations such as CR, J, K, L, P, S, T, TB, TP are in each set but must be used with the multiple numeric series (which are also in the set).

To use, just place your drawing over a hard surface and position the designation. Transfer the designation by rubbing the sheet with a round stylus, such as the cap found on some ballpoint pens. After transfer, cover the pattern with the burnishing sheet and rub again to smooth the pattern down and activate the adhesive.

Two sheets, each containing a complete set of designations, are available for only *\$1.25*. Order AN1X from Trumbull, 833 Balra Drive, El Cerrito CA 94530.

ELECTRONIC KEYER

Palomar Engineers has introduced a new IC keyer that takes less space on your operating table than the old semi-automatic mechanical key.

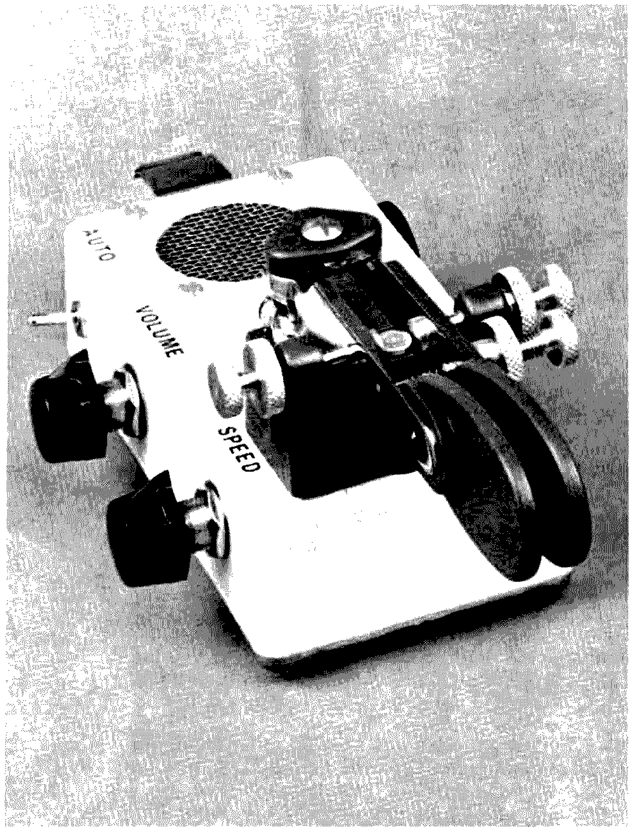
The new keyer sends semi-automatic, full automatic, self-completing, dot memory, iambic, and as a straight key. It has a built-in sidetone oscillator and speaker, volume and speed controls, automatic/semi-automatic switch, weight adjustment and battery holder. Any desired speed from 5 to 50 wpm can be selected while you send. The keyer is easy to learn and easy to use.

The IC keyer will key any transmitter, whether grid-block, cathode-keyed or plate-keyed, up to 500 volts and up to one ampere keyed current. Keying contacts are silver, and withstand heavy surge currents and voltage spikes.

The built-in paddle is fully adjustable for spacing and tension. A die cast metal case provides full rf shielding.

The clip-in 9 V transistor battery will power the keyer for about 75 hours of normal operating, making the keyer ideal for portable operation. At the home station, a lantern battery will last for about two years.

The keyer sells for \$87.50 postpaid in the U.S. and Canada. California residents should add sales tax. To order, or for free brochure, write to Palomar Engineers, P.O. Box 455, Escondido CA 92025.



Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

"Looking West" is heading east once again for our yearly visit to the homeland and, oh yes, to the Dayton Hamvention. While back there, we hope to have a chance to meet with some of those responsible for the new New York area "Tri-State Repeater Council" and thereby bring you some information as to how they got going and what their plans are for the future. In the meantime, the following release sent to us by Steve Mendelson WA2DHF will probably be of interest to you.

"On December 6, 1975, a formation meeting was held at Rye, New York with ARRL Hudson Division Director Stan Zack K2SJO as the host. Owners/operators from over 100 repeaters were present and agreed on the need for a repeater council to coordinate growth and negotiate disputes in the metropolitan New York, Southern Connecticut and Northern New Jersey area. The name chosen was the Tri-State Repeater Council. An interim board was chosen with Dave Minott WA2EXP President, Derwin Stevens WA2DHA Vice President, Steve Mendelson WA2DHF Secretary, and Sid Lieberman WA2FXB Treasurer. Directors were then chosen by caucus method with the group breaking up into telephone area code divisions.

"An executive meeting followed in the middle of March and a constitution was drawn up to be presented to the membership at the March 20, 1976 regular membership meeting. At that meeting, the board and officers were made permanent, and a 450 MHz band plan was presented. The band plan would have repeaters operating on 100 kHz channels and 50 kHz channels going high in/low out, while allowing repeaters operating on the 25 kHz channels to go either high or low in. As most of the repeaters in the area are low in now, it would allow them to slide down to a 25 kHz channel and cause almost no inconvenience to users now on these systems. This will also allow repeaters in the area to agree with the ARRL 450 MHz band plan, and take that plan one step further with the 25 kHz option. As you know, it is impossible to run a 450 MHz system in the New York City area without a vast amount of desense due to the commercial repeaters coming out low, and the amount of white noise generated by the dense rf population of the city.

"The Council approved the plan and constitution and went on to set up committees to operate within the Council and, as with all organizations, set up a minimal dues structure. The Council welcomes all area owners/operators, and has already served as a means of solving the problems that are generated by operating in a high rf environment. The Council also serves as an informal setting for owners to get together and enhance each other's technical abilities.

"Those interested in applying for membership should write to: TSARC, PO Box 402, Amityville, New York 11701 for information. Or, if in the tri-state area, contact one of the officers of the Council. Our structure also makes provision for membership of those waiting for their repeater license. To those who would want to put up a repeater in the tri-state area, they are requested to contact Duke Harrison K2QPF who has agreed to continue his fantastic job of frequency coordination for the Council."

Speaking for myself, and as one who was deeply involved in that area's "repeater scene" but a few short years ago, I truly welcome the establishment of this new organization. If only it had existed in my time. I have known both Dave and Steve for a long time and sincerely feel that they are the type of technologically competent people to provide leadership — and I wish them and TSARC all the best in coming years. I also wish to thank them for choosing "Looking West" to make their first major national announcement about the formation of TSARC. I consider this an honor.

Now, back home. I had promised to begin covering the WR6ABB/WR6AFR problem and had set the guidelines last month as to how it will be handled due to my involvement with one of the two organizations as a control station for WR6ABB and member of the PARC Executive Board. (See June "LW" for a more detailed explanation.) In short order I received a request for a bit more time from one of the parties and from the SCRA since negotiations are in progress to solve this dilemma. Hence, without all the "answers in hand," I do not feel it would be fair to cover this topic right now, so you might say that I am "copping out" at the moment in deference to all parties involved. Hang tight and in the near future you will have the story in the most objective and credible way it can be presented.

Have you heard the "Dick Van Dyke for Amateur Radio" PSAs on your favorite radio station yet? Thanks to the hard work of Byron Paul WA6RNG, who made the arrangements, and the fine editing work done by Lenore and Bob Jensen, W6NAZ and W6VGQ respectively, these spots tell the public about many of the interesting aspects of amateur radio and the simple way that one can become part of the amateur radio community. If you either work at or own a radio station and can air these PSAs, then a note to Mr. Don Waters, ARRL Public Relations Director at Newington, should bring your station a copy. In the meantime, a hearty thank you to all involved in the project, especially Mr. Dick Van Dyke for making it a reality.

A massive education effort of any sort is only possible if you have the people to train. In the case of amateur radio, one of the best places to find possible candidates is within the ranks of citizens radio operators. To tackle this possibility, an excellent new film is now being produced by Dave Bell W6BVN of "Ham's Wide World" fame. The new film, unlike Dave's previous efforts, is specifically designed to be presented to audiences of citizens radio operators who are interested in taking that "next step" and need the proper incentive. Hosted and narrated by Roy Neal K6DUE of NBC News, the film compares both forms of radio interest as well as explaining the many diverse aspects of amateur radio itself. From Novice operation to DX to repeaters — all important aspects of our hobby are covered, and thanks to Dave's genius as a film maker, covered in a way most enjoyable as well as educational. As to when this film will be ready, I am not sure at this time; however, again a note to Don Waters in Newington can possibly bring more info. I had a chance to meet Don a few weeks ago at an amateur radio PR seminar here in LA, and I am most impressed with the gentleman. He is a true professional doing his best to publicize amateur radio for us. Really enjoyed meeting him. Oops — the title of Dave's film? "Getting Started in Amateur Radio."

While on this topic of PR and the like . . . you have probably noted on the "tube" the myriad of commercials to sell CB equipment. This note is directed to those manufacturers so involved in that advertising. Many of you are involved in the manufacture and distribution of amateur equipment as well as CB gear. With CB expansion, temporarily at least, at a standstill, and the "big city" log jam what it is, and with many of today's CBers looking for "something better," it might be prudent to consider advertising your amateur line in the same way and perhaps become directly involved in the training of amateur radio operators. If the Commission refuses any further CB expansion, then in many areas the CB market will be saturated within a few years. When that happens, new markets will be necessary and it is a smart businessman that looks to the future. A very lucrative market can easily be developed if you have the interest. At least it's worth a thought.

Finally this month, we wind up coverage of the Guatemalan disaster relief effort by amateurs here in the southland and nationwide. I suspect that Bella Russ TG9HS expressed the feelings of her people best in the following message sent via amateur radio to the people of the USA: "This is TG9HS and my message goes to the people of the United States of America. It has been one week since the world stopped; have you heard about it? Every second, every minute that goes by we wonder if we will make it to the next hour. What happened?

"One of the worst earthquakes in world history hit our nation. So far we have counted 20,000 people dead, 50,000 people wounded and 1,000,000 poor people homeless. When and if we ever finish counting, God knows how many will be dead. It all depends.

"We are praying to God to please stop shaking our area. We have a tremor on the average of one every five minutes. Still we are not giving up. We are not defeated. Our people are working hard to help each other. We know it will not be easy, but we will rebuild our country if it takes the last breath of all Guatemalans.

"America, you have felt our despair but you also sense our spirit. Today the people of the United States are showing the true colors of the name compassion. Your help, food, medicines, doctors, nurses and hospitals are arriving in Guatemala and you can ask your newsmen who have seen it. It is being used as fast as it arrives and is being used where it is most needed. And on behalf of my people and government, our sincere gratitude to all of you and especially to your wonderful amateur radio operators who have been in constant communication in our emergency."

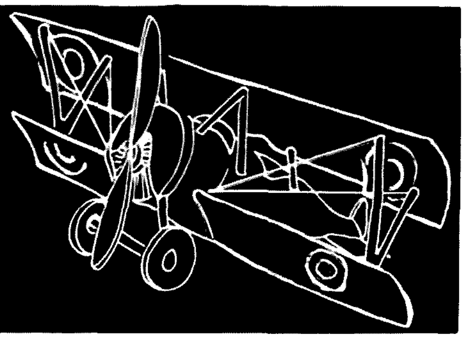
It has now been several months since that message was sent from the people of Guatemala to the people of the United States. Still the rebuilding goes on, and one has only to listen to low band QSOs between TG stations and others to realize that amateur radio is still involved in this effort. Though the media gave us little in the way of public recognition, still we, the amateurs of the United States, were there when all else failed, and there to begin the massive aid effort. No, the White House never issued any official proclamation commending our effort, and no one has done a "TV Special" about amateur radio's role in helping the people of Guatemala. I guess we are just not big or important enough for anything like that.

One thing I do know, however. If any disaster ever befalls any nation, and if at any time the need arises to provide communication where all other methods fail, amateurs like you and me will be there, and we will do it again and again. When all is said and done, that's what amateur radio and its people are truly all about. Walk tall, guys and gals; being a "ham" is something to be proud of!

My special thanks to Doug McDowell K4SWJ/6 and Shelly Chelsey WB6KED of the Palisades Amateur Radio Club and Bill Orenstein KH6IAF/6 of CARS for making the tape available from which Bella's message was transcribed.

Continued on page 22

Autobiography of an Ancient Aviator



W. Sanger Green
1379 E. 15 Street
Brooklyn NY 11230

It was a bright, sunny morning in May, 1929. I arrived at Central Airport (Camden, N.J.) at eight o'clock, checked progress of the construction of the two new hangars, and went to my temporary office in the old hangar lean-to. I was looking over the morning mail when Bob Hewitt, manager of the Ludington Philadelphia Flying Service, phoned and asked if I could take a charter trip to Cincinnati that morning. I asked what the nature of the trip was, and he said they wanted to transport a man's body, his widow and two brothers. He proposed to use their Fairchild 71, so I said I'd check the weather and call him back. The Weather Bureau's forecast for the route was good, so I called Bob and told him to send the 71 over to Central from Philadelphia and I'd take the trip. He said he would have the party there by 9:30 and that the Philadelphia undertaker would make arrangements to have us met at Lunken Airport, Cincinnati, at about four that afternoon.

The party arrived at Central on schedule, but when I got a look at the basket the body was in I knew we weren't going to get it in the plane door. So I had them drive the hearse over to the far side of the field where there were no onlookers and I taxied the plane over. We had to take the body out of the basket, tie it in a seat, cover it, load the passengers and take off from there.

The flight was uneventful, weather C.A.V.U., and, after a brief refueling stop at Bettis Field, McKeesport, Pa., we arrived at Lunken Airport at 3:50 that afternoon.

Unloading at Cincinnati was not quite as discreet as our loading at Camden. I turned the ship so that the unloading door was away from spectators and the field personnel managed to keep photographers from taking pictures of the proceedings. Nevertheless, one of the Cincinnati papers carried a story about the "Flying Hearse."

That evening I had a sort of 1922 Cadet Class reunion with John Paul Riddle, "Jiggs" Huffman, and "Dubissary" Harris. They were then pilots on the Embry-Riddle Airline that operated a contract airmail route between Cincinnati and Chicago. In the morning I had a good tail wind, so I was back at Central in time for lunch.

The Jacobs Engine Co. was located at Central Airport, and from time to time I did some test flying for them. One test I'll always remember was when they had mounted a small engine of their own design in an Aeronca Scout single seater. Tom Carrol was their test pilot, but he weighed over 200 lbs. and couldn't get the ship off the ground. At that time I weighed around 140, so Al Jacobs asked me to try it. Early the next morning, when the air was its heaviest, I tried to take the ship off – but it would only get a few feet off the ground. So I taxied it back to the factory and shed all but my shorts. This time we got off and up to a ceiling of about 40 feet, so I made a very wide trip around the field and came in for a full power landing. I guess Al figured that his little engine was only good for lawn mowers. I never heard anything more about it.

My office in the new administration and station building at Central Airport had a large picture window facing the field. One morning I was working at my desk when I happened to notice a small Cessna coming in for a landing. Just as he came over the fence at the far side of the field I thought I saw a large object drop from his plane. He landed OK and taxied in to the line, killed his engine, and sauntered over to the hangar – giving no indication that anything had been amiss. I was so sure I had seen something drop that I went out and inspected the plane. Nothing was wrong there, so I picked up the pilot and drove to the far side of the field. It didn't take long to find a young man lying there unconscious. He seemed to be breathing all right and his pulse was OK, so I called an ambulance and had him moved to a local hospital. After a complete check, the hospital advised that he had no injuries that they could discover and that probably his "wind was knocked out" when he hit the ground.

How could an accident like this happen? Well, the pilot's story was that he had landed in a pasture about four miles away and, after visiting some friends nearby, was ready to take off for the short hop back to Central. Since the field was quite short, he had asked a couple of men to hold down his horizontal stabilizer (one on each side) until he had "revved" his engine up, and to turn loose when he waved his hand out of the left window. It seems that he opened his throttle wide and waved out of the window OK. The man on the left stabilizer saw it and jumped away, but the man on the right didn't see it and before he knew it the plane was gathering speed and the air pressure had him glued to the stabilizer. When the pilot came in to land he reduced his air speed enough to take most of the pressure off the man clinging to his stabilizer and allow him to fall to the ground. Not a broken bone. Not a bruise or abrasion. A miracle.

On a Saturday in May, 1931, I had a rather unique flying experience. They were having an air meet at the Philadelphia airport that afternoon, and one of the attractions was a "Sportsman's Pilot Race." It was open to anyone with an airplane. They had sixteen entries and, since there was such a difference between the planes involved, they decided to give each one a handicap. To do this they wanted to have each ship timed flying over the same one mile course at full throttle and piloted by a neutral qualified pilot. So they asked me if I would take on the job.

The procedure was for me to take each ship off from the Philadelphia Airport, make a wide circle at low altitude, fly low at full throttle over the timing course, come back around the field, and land. When I took off with one ship, the next to be tested was to have its engine started so that I'd lose no time in transferring from one ship to the next.

At this point I might say that the Philadelphia Airport in those days was little more than a flying field. It was small, had no runways, and the approaches left a lot to be desired. Anyway, we got the tests started promptly at 8:00 am, and from then until 12:30 I flew sixteen different airplanes over the course to qualify for their handicaps. The types varied from an Aeronca to a Taperwing Waco. Each had its own characteristics, but fortunately they all behaved well for me that day. It was an experience. The race went off on time that afternoon.

Next month, more happenings.

CONTESTS

from page 12

MT. RUSHMORE BICENTENNIAL STATION

The Black Hills A.R.C. will be operating a bicentennial special events station (NSØDAK) at Mt. Rushmore National Memorial, in the Black Hills of South Dakota, on July 3rd, 4th, and 5th. We hope to operate SSB and CW on General and Advanced portions of 80 through 10m and 2m FM. Special QSL cards will be available. Please QSL with SASE to KØCXL at 715 San Marco, Rapid City, SD 57701. Their authorization is good through September 6, so watch for them on other weekends and holidays.

SPECIAL "VIKING" LANDING COMMEMORATIVE

The Jet Propulsion Laboratory Amateur Radio Club (JPL-ARC) will be conducting one of its active participation programs for this year by making contacts with other amateurs all over the United States and many foreign countries in conjunction with the bicentennial project of landing on Mars.

The JPL-ARC will be active "on the air" with a special commemorative program during the Mars encounter by the Viking I and Viking II spacecraft.

Each of these spacecraft is comprised of two parts. One section is used to orbit Mars, while the second section is designed to land on the surface of Mars. Many scientific experiments will then be made, primarily to determine if there is or was any biological life on the planet.

The JPL-ARC will be using the special call of N6V (N = NASA, 6 = 1976, V = Viking), operating from Pasadena, Calif., and will operate on the following approximate frequencies: CW – 3530, 7030, 14030, 21030, 28030 kHz; SSB – 3810, 3930, 7230, 14225, 14325, 21360, 28630 kHz; Novice CW – 3730, 7130, 21130, 28130 kHz.

The exact time and dates of operation have not at present been determined because they are dependent upon the Viking spacecraft schedules. The closest approximation is: Viking I arrival at Mars, June 19, N6V on the air June 18 to 23; Viking I landing on Mars, July 4, N6V on the air July 3 to 18; Viking II arrival at Mars, Aug. 7, N6V on the air Aug. 6 to 12; Viking II landing on Mars, Sept. 4, N6V on the air Aug. 31 to Sept. 15. Viking status reports may be secured by calling (213) 354-4213.

Looking West

SOUTHERN CALIFORNIA AMATEURS HONORED

On March 4, 1976, the Honorable Herschel Rosenthal, Assemblyman from California's 45th Assembly District, presented the following resolution to the Amateur Radio Community of Southern California:

RESOLUTION
Relative To Commending
The Radio Amateurs Of
Southern California

WHEREAS, The Amateur Radio Operators of California have provided important public services for more than 50 years to the people of the state, and are deserving of special recognition for their outstanding record of dedicated community service, and

WHEREAS, The Amateur Radio Operators of California and their American Radio Relay League provide vital emergency communications in times of natural disasters, such as fire, flood, and earthquake, and, in particular, the recent Guatemalan tragedy; and

WHEREAS, Inducing a constant strengthening of international friendship through their contacts with every country in the world, the Amateur Radio Operators, through their inventive and resourceful experimenting, led to the development of broadcast radio and its continued improvement; and

WHEREAS, They provide exemplary services in providing "phone patches," linking overseas servicemen with their stateside families; and

WHEREAS, The sophisticated Oscar satellites circling the globe make interpersonal contact by radio waves possible in remote areas, providing information for all occasions, including knowledge of space to school children, and emergency assistance to motorists, police, and stranded persons; and

WHEREAS, The study, training, and practice of the amateur radio operators has provided the state and country with a huge reservoir of technical skills for the armed forces; and the activity provides a useful pastime to many of the shut-ins and isolated individuals of the state; now, therefore, be it

RESOLVED BY ASSEMBLYMAN HERSCHEL ROSENTHAL, That the Amateur Radio Operators of Southern California be commended for their outstanding record of dedicated and highly effective service to their community, state, and nation; and be it further

RESOLVED, That a suitably prepared copy of this resolution be transmitted to the Radio Amateurs of Southern California.

Members Resolution No. 395
Dated: March 4, 1976
Signed: Honorable Herschel Rosenthal 45th Assembly District

On hand to accept this award on behalf of the entire area amateur radio community was Jay Holiday W6EJJ, ARRL Southwestern Division Vice Director, along with many of the amateurs who had participated in this area's mass communication aid effort for Guatemala (including Doug McDowell K4SWJ of the Palisades Amateur Radio Club, organizer of this aid effort).

How Do You Use ICs?

--fundamentals

Most of the articles dealing with integrated circuits (ICs) either explain the theory of internal electronic operation or show some complex use for the device to someone who is already familiar with ICs.

It is not necessary to have an understanding of how they work to begin using and enjoy working with ICs. What is needed is the nuts and bolts practical information on how to get started usually overlooked by the more advanced technical article.

The IC can be basically thought of as a miniaturized printed circuit (PC) board. It is a complete electronic circuit within its package, built to perform some specific function.

This is both the problem and the key to easily working with them. Instead of working with components and building a circuit with them, you are working with the complete circuit as a plug-in unit adapted to your purpose.

The cheapest and most obtainable IC surplus available is the digital type. This was designed for computer use. Amateurs use it two basic ways: as it was designed when they can use that particular IC function, and by externally manipulating it to perform some unrelated function that it was never designed for.

Many counters use digital ICs to count the same way a computer would. Other equipment takes the computer circuit and makes it work as an amplifier, product detector, oscillator, and so forth.

This article will try to answer some of the more obvious questions about how to start working with digital ICs and get usable results. The first question is:

How Do I Tell What These Devices Are?

An IC is named for the particular computer function it performs in a digital computer. Most of the time the name will not be of any value to the amateur, except to identify the device to be used. He will be using it in a different way for a different purpose than it was intended.

It also has a code number, as tubes and transistors do. There are a limited number of

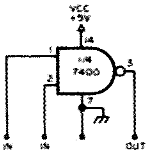

Fig. 1.

specific computer functions, but a variety of ways they may be packaged.

An IC package may contain only one actual circuit, or it may have a number of them inside. This is for computer building convenience. It may seem confusing at first that so many code numbers seem to be the same circuit, but they may be different combinations within the package.

An IC also belongs to a "logic family." This heading is usually given over the list of code numbers in the ads. This refers to the electronic means by which the circuit does its work.

The circuit function can be performed a number of ways electronically. While this is important for computer use, it is less so for amateur use. When you become more experienced, the need to become more selective about which logic family you use may arise – but not when you are starting out.

Where Do I Get More Specific Information?

Check the ads and send for the catalogs of surplus IC dealers. This will give you at least one number/name cross reference that you might need.

When you order, for a slight additional charge you can get the data sheets for the devices you order. If you plan to do a lot of work with ICs, there are several data books available on the common IC families (for about three dollars each).

Careful reading of IC articles will also give you quite a bit of information. One article may not give it all, but comparing several will yield something you can use.

With So Much To Choose From, What Do I Start With?

The important thing is to begin. Keep it simple. Some particular devices are standing out as most commonly used.

The family to start with is the TTL (transistor transistor logic) family, also referred to as T^2L. These are cheap, rugged and available.

Within this family there are two devices which are well known and easy to work with. They are the 7400 quadruple dual input NAND gate and the 7490 decade counter. Forget the names and look for the numbers. You may just see "7400 gate" and "7490 counter" in the ad.

What Can I Do With Them?

The 7400 is the heart of many IC oscillator circuits, and is often adapted to perform other common circuit functions. This is one area where the device is adapted to perform tasks it was not designed for.

The 7490 likes to divide

by two, five and ten. It is the heart of many dividing and counting circuits. This is a case of the device being used as it was designed.

One obvious use would be to combine the two and make a multiple output frequency standard such as 100 kHz, 10 kHz, 5 kHz or a custom output for a particular use.

By learning with the simple circuit you get the practical basics of the more complex dividing chains used in counters or other exotic gear.

These are basic circuits. The 7400 has also been adapted to perform many of the functions of a complete SSB generator, acting as oscillator, mixer, buffer and so forth. This makes it a good device with which to learn the basics of external circuit manipulation.

What Else Will I Need To Get Started?

Besides a few ICs to play with, you will also need a few basic items to start off with. These should be thought of as capital investments. You will use them over and over again as you work.

You will need a power supply. For digital ICs you need 5 V dc, preferably regulated. This is no problem and will be dealt with later.

You will need one of the IC breadboard matrices. For experimental circuits, there is no more practical way of working with them. Printed circuit board techniques are clumsy and don't lend themselves to quick changes. Individual sockets and components are much too fussy to work with conveniently.

You will also need a supply of small parts to use with the ICs. There are fewer used with an IC circuit than with tubes or transistors, and with careful buying they are much cheaper.

What Is It Going To Cost To Get Started?

The initial investment will be in the neighborhood of thirty-five to forty dollars, most of which is for non-expendable items used over and over again.

This compares favorably with what you would spend on a comparable breadboard setup for tubes or transistors if you started from scratch.

After the initial investment, the cost per circuit will be lower than with tubes. Careful planning of purchases and buying ahead at quantity prices can bring the cost way down.

The biggest expense will be the IC breadboard matrix. The Proto Board 100 at \$19.95 (plus postage) or the AP Superstrip at \$17.00 (plus postage) is probably the best investment.

Plenty of ready-built supplies, kits, and individual parts to build supplies are available surplus for between five and ten dollars.

As for the rest, five to ten dollars will buy a good supply of 7400s and 7490s, and a fistful of the small parts you will need to build a lot of the basic circuits.

The initial high cost will also be offset by the fact that, with the use of the breadboard matrix, you will be able to use the small parts over and over again without cutting the leads.

After the initial investment, the cost per additional experimental circuit will be much less than with tubes.

What Kind Of Power Supply Will I Need?

Digital ICs want 5 volts dc, preferably regulated. This is not hard to arrive at. It is much easier than with tube supplies.

While a complex piece of IC equipment might draw several Amps, for an experimental supply anything from 200 mA to an Amp will be satisfactory. Even a battery will run several ICs.

Linear ICs work from a wider range of voltages, usually in the 9-18 volt class, and there are some types of ICs (like differential amplifiers) which take two voltages – one plus, one minus – in that range. This sounds harder to do than it is, but start with the digital IC and the single supply.

What About Voltage Regulation?

Here is where you really get a break with ICs. A well regulated dc tube supply is quite an undertaking. With ICs, it's a breeze.

If you have a transistor-type bench supply in the 9-12 volt range, just add an IC regulator such as the LM309H (\$.75 to \$1.50, depending on the source) and your supply problem is solved.

These come in a variety of packages which look like familiar transistor types. They have three leads: one input, one output, and one ground. Can't get much simpler than that. They will handle about one Amp each.

What About Additional Filtering?

It is best to regulate the voltage right at the IC unit, which makes the IC regulators ideal. If the power supply is at a distance from the unit, it is best to bypass the input with .1 uF or more.

It is also advisable to bypass each IC package with .01 to .1 uF, to prevent interaction between ICs. This may not be needed experimentally and not all finished circuits will need or have it.

When you are ordering parts, include a few regulators and some disc capacitors. They are quite cheap.

Where Does The Power Go?

Many partial schematics are ambiguous about some of the IC connections. As with tube circuits that don't show the filament circuit, assuming that you know where it goes, the IC circuits use a form of shorthand.

Most ICs have a pin connection for the source voltage (Vcc) and a ground return for the other leg of the voltage. Many times this is just not shown.

With a multisection IC, there is still just the one Vcc input which feeds all the sections.

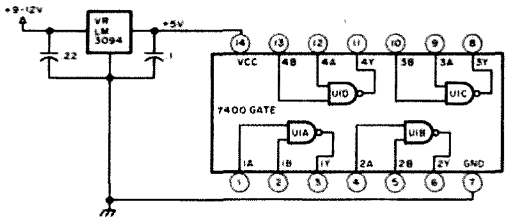

Fig. 2.

How Do I Read The Schematic?

Reading IC schematics is easy once you know how. Two systems are used. The first is to use the actual computer circuit function schematic symbol. This is often used when a multisection IC is broken up to perform several functions.

The important thing to remember is that the computer symbol is only used for convenience and usually has no computer meaning in the circuit.

The numbers on the pins refer to the pin numbers of the complete IC package. An example is shown in Fig. 1, which is one section of the 7400 with the pin numbers shown. The other three sections would be drawn the same way, with the correct pin numbers for each.

Often the entire IC is shown as a rectangle with the pin numbers on it, making it look like a large rectangular tube socket. The important thing here is that, unlike tube sockets, the IC pins are counted from the top of the case. Pin one is usually located by a mark.

Since most ICs are used with printed circuit boards, most of the other parts are top mounted; thus, the pins are shown from the top of the device.

Fig. 2 shows the complete 7400 IC package with the four sections drawn inside and the pins numbered. Also shown are the Vcc pin, common pin, and the associated bypass and voltage regulator, for basic recognition of the complete unit.

Can I Use My Junk Box Parts With ICs?

For outboard things like power supplies, switches, chassis, and chassis mounted parts, you probably can. For the parts directly connected to the IC, it is unlikely. They will be too big to fit conveniently and the leads may be too thick to use with the IC matrix without damage.

Considering the low cost of miniature surplus IC components and the convenience of using them, this is no problem. Use what you can of what you have. The little parts are cheap.

Where Do I Find Circuits?

Basic individual circuits are now common in most of the magazines. The larger articles may have what you need as part of another device which you might not want all of.

Can I Adapt Circuits From Other Pieces Of Equipment?

Very often you can. Unlike tubes, ICs are designed to be building blocks. The ICs in a family are designed to interface with each other.

Often it is possible to isolate the IC and its external circuit components that you want, and use it in another project without serious modifications.

How Are IC Circuits Coupled?

The two most common methods of coupling are direct coupling, where one output pin of an IC goes directly to the input pin of the next IC, and capacitor coupling. This makes it very simple most of the time.

What About Unused Leads Or Sections?

There is no hard and fast rule. Many ICs have such high gain that a floating input pin or section can cause instability problems. There are several ways of dealing with this.

One of the safest general methods is to return all unused input leads to the Vcc pin through a 1000 Ohm resistor. It is not necessary to use separate resistors for each lead. All leads from the IC can be returned through the same resistor.

Look at similar IC schematics. Sometimes the lead will be left floating or will be grounded. With grounding, some ICs will draw too much current. A milliammeter in the Vcc line will show you what the current is doing.

Transistors Are Easily Damaged; What About ICs?

ICs are quite rugged. Manv problems are simplified because they are matched to be interconnected. The most critical voltage is the Vcc voltage. There is a very small range above and below this in which ICs will work properly without damage. Using the small IC regulators will take care of this.

The next thing to watch is that they aren't overdriven. If you are using ICs with each other, this is unlikely, but if you are using an external drive voltage it may cause damage – the same as overdriving a transistor.

Don't let that scare you. It is not too common. They are quite rugged compared to transistors and they are very cheap. At 20¢ or less for a 7400, you can blow out quite a few learning and never feel it.

What About Using Other ICs?

The 7400 and the 7490 were chosen here because they are commonly used and information is readily available. There are plenty of others which can be used.

The basic oscillator circuit uses two gate sections. There are other computer gates which will also work. If you happen to have a stray IC gate type which is not a 7400, try it in the same type of circuit. It may work and it won't hurt to try.

Check through the IC articles and keep a file of the types of ICs used. The next most commonly used will show up that way.

What About Linear Devices?

Once you have gotten past the IC hurdle and have worked a bit with the digital type, you can begin to expand. As the prices come down, it becomes attractive to try the linear devices.

The regulator ICs you will be using are linear devices. The others which you might be interested in are the types that perform some radio or other desirable amateur function without the need for external fudging. They are

IC SHOPPING LIST

Power Supply

5 volt regulated or 9-12 volt transistor type
9 volt transistor radio type battery

Matrix

Protoboard 100 (@ $19.50 + postage)
AP Superstrip (@ $17.00 + postage)
Protoboard 6 (@ $15.95 + postage)

IC Types

TTL digital 7400 series
7400 gate, 7490 counter
Linear LM309H, K or equiv. 5 volt regulator

Capacitors

Supply of disc type 25-50 V
0.1 uF, 0.01 uF

Resistors

1/4 Watt carbon. Most used values for ICs listed: 150, 220, 330, 470, 560, 680, 1k, 1.8k, 2.2k (Available in sets quite cheaply with more values in set)

Hookup Wire

#22 or smaller solid

(Add other items needed for specific projects desired, in order to make up minimum order requirements, or get price break on quantity ordered.)

internally designed to perform that specific task.

One of the simplest and most available, directly applicable to many uses, would be the audio type IC. These range from dual stereo preamps to complete preamp/power amp ICs that are well within the range of what is used in communications work.

Working up from that, there are the ICs designed for commercial use which are complete i-f strips or complete subsections of communications type receivers. Some are specialized for FM or TV.

As these find their way into common amateur use, they may well put the design of simple but effective equipment back in the range of something which can be done with limited means.

Many of them will work with the IC matrix and a standard transistor-type supply. (5 volts is rather lean for the linear devices.) There are some that will not fit into the standard IC matrix, being designed for direct PC board use.

The thing to look for is the standard DIP (Dual Inline Package) configuration. Most of the ads will tell you if it is an unusual construction. Many of the audio power types have heat sink tabs. You can still use them, but not as easily as using the matrix.

What Am I Waiting For?

I don't know. What have you got to lose? Even if you blow out a few ICs while learning, they can be replaced for less than a buck. The initial investment is one of the cheapest available in amateur radio, when viewed in terms of the fun you will eventually have.

Set aside a little something each week and soon you'll have enough for the power supply, breadboard matrix, and a handful of ICs and parts. After that it should be downhill all the way. ■

KIDNAPPED: Drake TR-22 with crystals for 34-94, 94-94, 16-76, 04-64, 64-64, 88 receive. Texas D/L no. 4472525 on chassis. Jack Van-Natta WB5DYE, Tulsa OK. Phone (918) 627-3738.

ABDUCTED: Regency HR2A s/n 04-10422. Crystalled for 94/94, 34/94, 16/76, 52/52. Has bracket attached and cigarette lighter plug on power cord. Stolen from Don Billings WØGOH, 2838 N. Prospect St., Colorado Springs CO 80907, phone 303-636-1661.

FILCHED: Motorola two freq., control head, Motorola T-power mike, Moto. speaker, 16 button TT pad with light, mounted in Bud Box. Stolen from Jim Best WAØRZI, 1923 Alpine Drive, Colorado Springs CO 80907, phone 303-471-1486.

HIJACKED: Regency HR2B, s/n unknown. Crystalled for 34/94, 34/34, 16/76, 19/79, 22/82, 28/88, 88/88, 145.80/80, 58/58, 25/85. Stolen from Glenda Butler WBØOCH, 1509 E. 12th St., Pueblo CO 81001, phone 303-544-7777.

STOLEN: Atlas 210X xcvr s/n TH3214 with Lafayette mobile mike modified with 3 conductor ¼" diam. plug. Does not have dc power cord or ac supply. Also Lafayette HA-146 2 mtr xcvr s/n 1111 with mike, power cord and the following xtals: 52-52, 16-76, 76-76, 19-79, 22-82, 34-94, 94-94, and 147-69-09. If any info call collect (213) 374-8528. Les Goddard WB6URL, 2121 Clark Lane, Redondo Beach CA 90278.

PLUNDERED: EBC 144Jr., s/n 50108, synthesized rig. Stolen from Dick Sucher WAØZLY, 27 Leaming Road, Colorado Springs CO 80906, phone 303-471-1696.

LOOTED: Kenwood TS520 s/n 140579, engraved WA7WDC, and an Icom 230 s/n 2405651 also engraved WA7WDC. In addition about $7,000 worth of tools and test equipment. If anyone has any information to the recovery of the this equipment please notify the Phoenix City Police. G. M. Chinn WA7WDC, 906 E. Broadway, Phoenix AZ 85040.

ROBBED: Genave GTX 200, s/n 22-03, ss number inside 031-28-9354. Crystalled for 157.63-03, 147.06, 156.37-97, 34-94, 94-94 and MARS frequency. BNC on back for duplex operation. Extra relay inside for sw. mike and motor control head; early vintage set. Stolen from Gus McKinney WBØOFR, 807 Holmes Drive, Colorado Springs CO 80909, phone 303-473-1397.

HIJACKED: Regency HR-2, s/n 04-02604 with nicad battery pack attached, s/n 7157; with microphone. Rig had modifications for Topeka preamp and extra 6 channel crystal deck. Stolen from my car parked at Ramada Inn, 1900 Fort Myer Drive, Arlington, Virginia, night of March 31, 1976. If you have any information on this equipment, please contact: A. D. Abercrombie W2GJS, 1002 Merrymount N., Turnersville NJ 08012, (609) 227-1383.

STOLEN: FM-27B 2 meter, stolen from car. Has 410-30-6102 engraved on back and side. Contact Allen Eskind W4ZLW, 6104 Hickory Valley Rd., Nashville TN 37205.

LIFTED: Drake TR22 s/n 640995 was stolen from my car located in the parking lot at 2121 East 63rd Street, Kansas City MO between 8 am and 11 am CST on Thursday, April 8, 1976. The radio was marked on the chassis with my Social Security number and amateur radio call. Anyone with information concerning this radio is asked to contact the Kansas City MO Police Department (816) 842-6525 or KØIDJ.

TAKEN: Drake Model ML-2, 12 channel all xtaled, serial no. 11239. Touch Tone pad attached to top. Call K2YKE attached to side and marked several places inside. Stolen from my car in Buffalo, New York April 9th. Ken Haas, 243 Crosby Blvd., Buffalo, New York 14226. Phone 716-834-4083.

RIPPED OFF: Heath HW 202, series 00316 transceiver. Modified: BNC antenna connector, scanner with LEDs over top (extra) barswitch. Three switches to left not connected. Right switch turns scanner on/off. Wires were cut at back panel. Contact Dick Ellis W5YCK, 104 West Avenue A, Alpine TX 79830, phone 915-837-3728.

PILFERED: Regency HR2, s/n unknown. Crystalled for 34/94, 17/67, 25/85, 88/88, has owner's name inside. Stolen from Dwane Barber WAØWWO, RFD 3 Box 353, Greeley CO 80631.

MISAPPROPRIATED: Icom IC22A, s/n 3401802. Crystalled for 94/94, 34/94, 22/82, 28/88, 52/52, 16/76, 37/97, 87/27, 19/79. Call is engraved on back, accessory plug wired for TT, PTT, and 455 kHz output. Stolen from Bill Croghan WBØKSW, 1030 W. Colorado, Colorado Springs CO 80905, phone 303-471-7504.

TAKEN: Regency HR-2A, s/n 04-07989 taken from car in Harrisburg PA. K3NVO 495-38-8556 engraved on chassis. Has scanner board mounted over receive crystals and four red LEDs mounted vertically on left front panel for channels one through four. Call or contact Ronald Kaullen K3NVO, 6326 Blue Flag Ave., Harrisburg PA 17112.

Surprising Miniature Low Band Antenna

-- the DDRR low noise antenna (part I)

Joseph M. Boyer
17302 Yukon, Suite 63
Torrance CA 90504

Once upon a time ham radio was nice and easy. You just went out into your own half acre backyard, put up a pair of ninety foot telephone poles, and hung an eighty meter Zepp antenna in the sky. To work the old 160 meter band you fed the same sky wire as an "inverted L" against ground. On the higher frequency bands you played tuning games on the open wire, six hundred Ohm transmission line leading to that flat top until the rig loaded. Such olden, golden times are now only fond memories in the minds of old-timers.

Today the radio amateur has a serious problem finding enough outdoor space in which to erect *any* kind of antenna, let alone an optimum one. There is, however, at least one way out of this restricted space dilemma, a way taken by military forces a few years back: Use an electrically small antenna! Conventional forms of such antennas, whose physical dimensions are small in comparison to the operating wavelength, are rather famous for converting more rf input power into heat than into good signals on the air. Antennas, unlike any other component making up a radio communications system, have stubbornly resisted efforts at miniaturization. Over the last sixty years, however, a quiet but fierce technical battle has been waged in many places in the world in an attempt to reduce the physical size of the transmitting antenna while keeping efficiency within reason. This battle is far from won. Nevertheless, some limited progress has been made to date, as well as certain surprising gains made in terms of antenna function flexibility. As one of the weary but still enthusiastic veterans of this technical warfare, I felt that some of the newer radiating gadgets which have come forth from the melee should be of interest and value to the radio amateur in his present hour of need. In that spirit, the aim here will be not to merely describe what some of these electromagnetic devices look like, but to include enough technical detail about them so the ham can design and experiment with these radiators himself.

Most of the antennas discussed are forms of radiating rf transmission lines of small electrical size. Most of them have originated from military interest in reducing the vertical height and size of conventional antennas. They are still so new, however, that they exist in very small numbers as yet and only render service in military applications. As past research has disclosed that the loading coil-only approach is the least efficient way of reactance loading short antennas, all of these newer, more exotic antennas are brought to resonance using exceedingly low loss capacitance; they make up for their high Q, narrow bandpass nature by being capable of very rapid frequency tuning. Some, like the LPT, are even capable of widebanded performance at good efficiency – in spite of

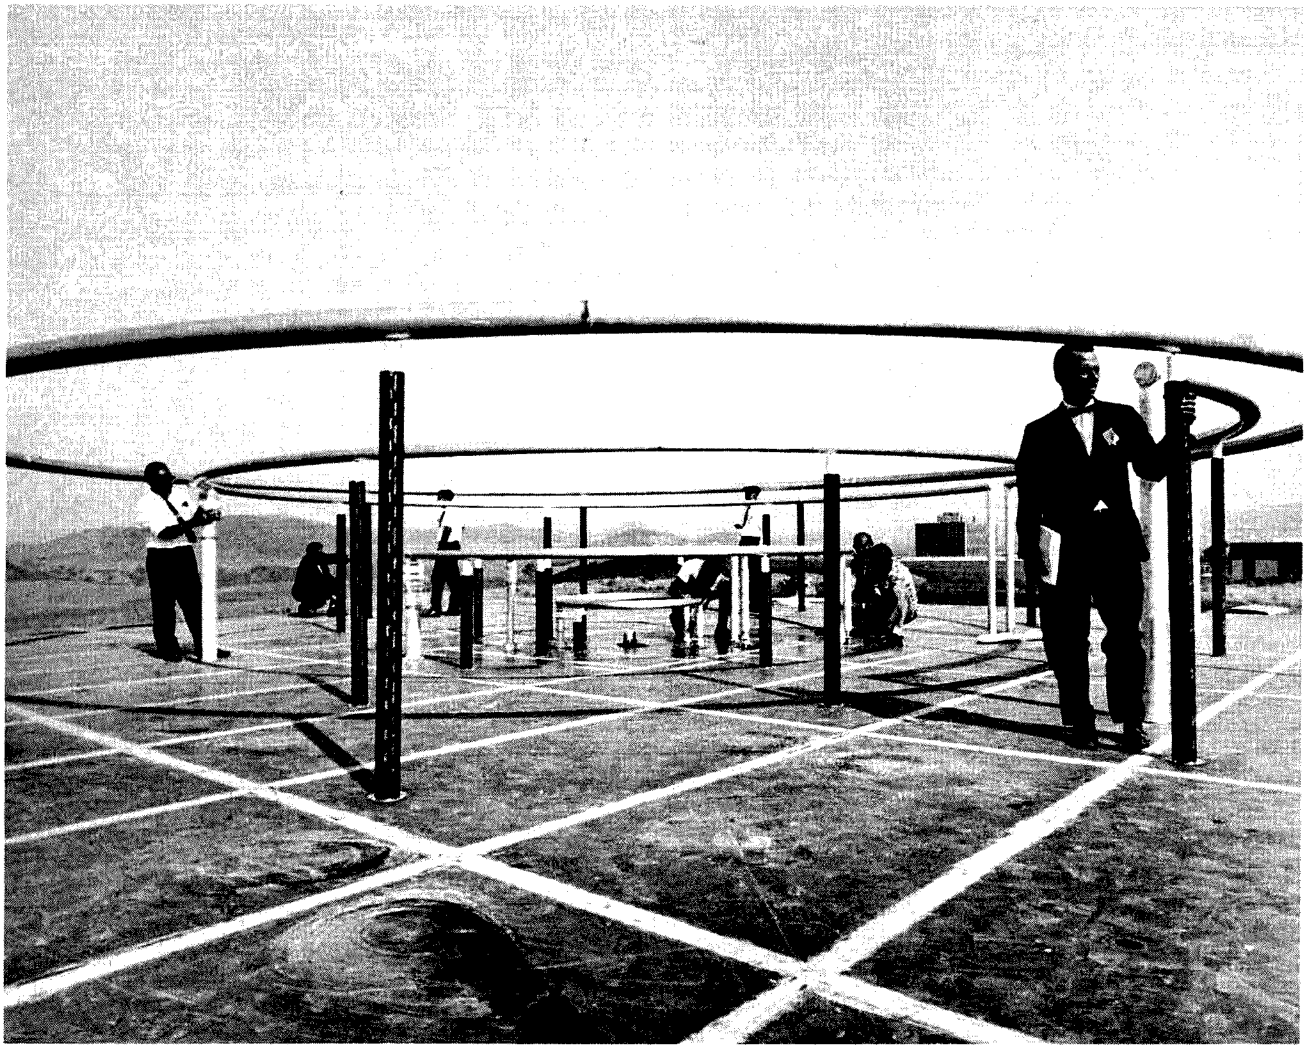

Fig. 1. Close-up view of military-type Directly Driven Ring Radiator (DDRR) antenna set up for long range communications tests in the 2.0 to 30 MHz frequency spectrum. Dark vertical posts supporting the ring elements are fiberglass tubing topped with "beehive" insulators. The hands of the engineer at the left rest on the 50 kV variable vacuum tuning condenser. The height of the ring in the foreground is six feet; the innermost 17.2 to 30 MHz ring element is 1.5 feet in height (Northrop Corporation photograph).

small height. All of them offer the ham with a small size QTH certain advantages over conventional antennas; some even afford a real advancement in overall ham band communications practice. Therefore, we will discuss the new antennas from the ham's point of view.

The Directly Driven Ring Radiator (DDRR)

The DDRR antenna[1] shown in Fig. 1 might well be called the *Little Wonder All-bander.* It tunes continuously from 2.0 to 30 MHz, and will accept *simultaneous* input from up to four 10,000 Watt auto-tune transmitters (Texas kW men and DX contest types take note!). The close-up view in Fig. 1 shows the DDRR set up for long range HF communications tests prior to being installed on the naval ship *USS Wheeling.* Fig. 2 is an aerial view of the same DDRR aboard the *Wheeling* during early sea trials. Although the rugged antenna operated well even when taking "green water" during storms at sea, it was later covered with a pillbox type fiberglass radome. Its location is on the roof of a helicopter hangar aft, the metal roof and surrounding sea serving as a highly conducting ground plane.

The maximum diameter of the *Wheeling* DDRR is thirty-five feet, with its outermost ring element at a height of only six feet above the ground plane. Although such dimensions may not immediately convey the idea of "small size," the antenna is seen to be "small" in terms of the four hundred ninety-two foot wavelength at 2.0 MHz. The *Wheeling* served in the Apollo space exploration program as an HF worldwide network control center, and is now off on similar scientific missions. There are a total of five concentric ring radiator elements. The outer one tunes 2.0 to 3.3 MHz, and the inner four rings tune the bands 3.3 to 5.7 MHz, 5.7 to 10 MHz, 10.0 to 17.2 MHz and 17.2 to 30 MHz, respectively. The ends of each of the ring elements are "grounded" to the metal image plane through metal

[1] U.S. patents (J. M. Boyer): #3, 151, 329; #3, 247, 515; #RE26 196; all assigned to The Northrop Corporation, Hawthorne, California.

posts. Half way around the circumference of each ring conductor, connection is made to ground through individual 50 kV rated, variable vacuum condensers. Each variable condenser is remotely controlled from the ship's radio room by means of two-phase servo drive motors of variable speed. Each DDRR ring element is directly fed with individual fifty Ohm coaxial transmission lines, no auxiliary impedance matching networks being required to obtain low vswr. Originally, provision was made to install reflectometers at the input terminals of each ring element to permit fully automatic servo tuning and frequency tracking with associated transmitters. To my knowledge, however, these units were never installed.

In the radio room there is a visual display readout console which gives constant information for (a) the identity of the transmitter currently in use with a given ring element, (b) the frequency to which each DDRR element is tuned, and (c) the vswr in each of the feedlines. In spite of all this automation, however, an experienced operator in total darkness can hand "slew" the tuning of the DDRR until a background noise peak is heard in a receiver tuned to the desired frequency. When the noise peak is observed, the input vswr in the feedline to the antenna is less than 2:1 and the antenna is ready to accept full transmitter power. Off this tuned frequency, the receiver connected to the DDRR sounds "dead," its S-meter resting on the zero peg.

In a DDRR, all antenna elements are at dc ground potential through extremely low impedance, high current capacity shunts. As a consequence, associated electronic equipment is quite well protected against damaging effects from voltage transients induced by lightning strikes on the ship's structure. Such dc shunts also serve as "static drains" during weather conditions when impact with charged snow or rain particles can build up very high magnitude voltage potentials on conventional antennas. Under such weather conditions, noise level during reception on the DDRR is a minimum of twenty decibels less than that attained on non-drained antenna systems.

Up to here we have been discussing a military antenna. Fortunately, however, I am able to give an account of how such a multiband DDRR operates on the ham bands. During preliminary land-based tests of the antenna in southern California, it was only natural that licensed amateurs serving as engineers and technicians on the project literally itched to know how the thing would work on ham frequencies. A notice of portable operation under the call W6UYH was sent off to Uncle, and one evening the gang adjourned to the large communications van nearby. To get a feel for band conditions using a standard radiator, a one hundred ten foot tall vertical quarter wave tower antenna was used to put out the first call on 160 meters. This antenna, of variable height, was available as a reference $\lambda/4$ monopole during military tests, and could be raised or lowered to ground within three minutes.

A number of contacts were quickly made with relatively local stations; naturally, excellent reports were secured using the big vertical skyhook. The QRN level was substantial and considerable Loran "buckshot" was noticed. The vertical was then dropped, and a touch of a control button sent the motor-tuned DDRR down into the high end of 160 meters (we had made sure it would "inch" a bit below 2.0 MHz, hi!). Almost immediately we heard a number of stations calling us from the Hawaiian Islands. The KH6s said they had been calling repeatedly since our first CQ. We had not heard their relatively weak signals, however, due to the fact that they were buried down under the QRN; now they stood out loud and clear against a much lower background noise level. We also observed that Loran buckshot was way down in magnitude and QRM from very near-channel strong locals was almost absent. To the island stations, there was very little, if any, difference detected in FS between the DDRR and $\lambda/4$ monopole in subsequent comparison transmission under conditions of slow fading.

As engineers, the hams present were a little surprised. We had all been somewhat concerned about the narrow frequency bandwidth of the electrically small height DDRR when operating efficiently with hard fought-for, low Ohmic environmental loss resistance R_Ω. Yet here, with this narrow frequency width antenna acting as a sharply tuned "bandpass" filter *ahead* of the first receiver stages, it was preventing loss of sensitivity due to random white noise loading, greatly reducing QRM and delivering a considerably superior signal-to-noise ratio advantage over the big antenna in a real world, *two way* HF radio communications mode. As one old-timer in the shack sagely observed: "You got to hear 'em, boys, before you can work 'em!" Shifting to 75 meters, it was the same story. Reception, using the relatively wide-banded tower $\lambda/4$ vertical, was a noise pain to the ear; on the DDRR we worked VKs, ZLs and Js, slicing them out from under the noise and QRM as if using a hot knife on butter.

Again, due to the unavailability of test stations on military assigned frequencies at intermediate distance range from our land-based test site, we were able to first observe on the ham bands another deliberately provided performance feature of the *two post* model DDRR antenna: the ability to work stations during daylight hours at distances greater than that of the ground wave fade out zone produced when using quarter wave vertical antennas. In the two post design DDRR, provision had been made to generate an auxiliary, very ***high angle*** radiation pattern lobe in addition to the DDRR's normal, vertically polarized, very low angle "doughnut" omni-pattern. In the lower frequency HF range of 1.0 to about 8.0 MHz, the ionosphere will strongly reflect signals incident upon it at high angles above the horizon. Such an effect is called the ionosphere "sounder mode" of communications and is of military interest because it can give contact range extension during daylight hours. We enjoyed daytime QSOs with stations ranging from 100 to 500 miles distant on 160, 75, and 40 meters — stations which could not be worked using the reference $\lambda/4$ monopole. Subsequent use of the DDRR on the *USS Wheeling* verified the same daytime range extension performance at sea on the lower HF channels outside the ham bands.

How the DDRR Works

Because many of the performance functions and much of the theory of the DDRR antenna apply equally well to the operation of other modern transmission line antennas to be discussed in Part II of this article, it is perhaps justifiable to give here some details about how a DDRR antenna works. While we are at it, we might as well give readers all the dope necessary to tailor one themselves for use in the ham bands. We're talking about an

optimum design, though, so that you end up with a compact size, efficient *antenna,* instead of a "heating element" for rf. Don't worry – no higher math will be used.

A DDRR can be designed for use in just one ham band, or as a model covering all amateur frequency assignments in the HF region. Once the design of a single band element is understood, there will be no problems in adding other band coverage elements. We will assume that the prospective user lives in a typical cramped-space, urban QTH where the installation of a really effective artificial ground plane system is completely out of the question for many practical reasons; to make the design even more attractive, a total vertical height of only six feet will be used in the example here, together with a selection of just one outside diameter conductor size to be employed in all conductors of the DDRR. The design relations given, however, are in such form that other conductor diameters, antenna heights, and frequency bands may be substituted as desired. Later, details will be given for adding the other elements to the one band design example to convert it into an allbander.

Fig. 3(a) shows a dual post DDRR like the *Wheeling* model, erected over a continuous surface, highly conducting ground plane. We will temporarily retain such a super ground plane for our discussion purposes here; later, we will *discard it* completely in the practical home QTH model. Also, we will end up with a one post DDRR, as the two post model does not afford the minimum size design we wish for ham use. In the drawing the rf currents are shown flowing in both the overhead conductors and as image currents in the ground plane at a single instant of time in the rf cycle. It is noticed that the directions of the currents in the ground plane are *not radial* like those produced by a simple vertical monopole antenna. In Fig. 3(b) just one half circumferential section of the two post DDRR antenna is shown in "straightened out" fashion. Because the part of the DDRR element of Fig. 3(b) includes a vertical post conductor, a horizontal conductor elevated above and parallel to the ground plane, a tuning condenser (C), as well as input feed terminals, it will function as a DDRR antenna element itself in our finished design.

Immediately, it would appear that all a DDRR really boils down to is a "one wire," unbalanced rf transmission line parallel to ground at a height h, and "shorted" to ground at one end by a vertical post. This ought to be easy! Now, we will agree with you that the horizontal conductor of total length S° parallel to ground does indeed form nothing more than a "one wire" rf transmission line "stub." But we are going to insist that you unlimber your imagination and go along with us in considering the vertical "shorting" post at one end of such line as *another* separate and different rf *transmission line* also. Any good amateur antenna handbook gives the formula for finding the characteristic impedance of the "one wire" line above ground in terms of its mean height (h) and conductor diameter (d). It is, merely,

$$K_c = 138 \log_{10} \frac{4(h)}{d} \text{ Ohms} \qquad (1\text{-}1.0)$$

Armed with equation (1-1.0), let us begin by selecting the 75 meter band for use in our example. We will start the design at the upper frequency limit band edge of 4.0 MHz. At 4.0 MHz, wavelength λ in air is 984/4.0 MHz, or 246.00 feet. We said we would use only a vertical antenna height of six feet. We will not be precise here and take into account the conductor diameter in determining the electrical length (h°) of the vertical post element at 4.0 MHz. Instead, we will arbitrarily select 4.0 inch O.D., thin wall, aluminum alloy tubing (type 6061T6 or other weldable alloy) for both the post and horizontal conductor. Taking the post height (h) as 6.0 feet, its diameter of 4.0 inches as 0.33 feet, and its radius as 0.17 feet, we find the following "electrical dimensions" at 4.0 MHz:

$$h^\circ = 6'/246.0' \times 360^\circ = 8.78 \text{ degrees}$$
$$d^\circ = 0.33'/246' \times 360^\circ = 0.48 \text{ degrees}$$
$$a^\circ = 0.17'/246' \times 360^\circ = 0.24 \text{ degrees}$$

Knowing these dimensions allows us to use (1-1.0) to get the characteristic impedance (K_C) of the "one wire" over ground horizontal transmission line section as,

$$K_c = 138 \log_{10} \frac{4(8.78^\circ)}{0.48^\circ} = 138(1.86) = 256.70 \text{ Ohms}$$

Turning now to the vertical post itself, it appears that we face a problem in determining its characteristic impedance as an rf transmission line. For example, we know that another way to define the characteristic impedance of ordinary rf transmission lines is in terms of the ratio of the distributed series inductance (L) of the conductor to its distributed shunt capacity (C) between the conductors. Such a relation is written as $Z_O = \sqrt{L/C}$ Ohms. We know we would get K_C equals 256.70 Ohms for the horizontal line section by this alternate formula if we could just measure the distributed series inductance (L) along our 4.0 O.D. conductor and its distributed shunt capacity (C) to ground per *unit length.* Such characteristic impedance is constant along the entire length (S°) of the horizontal DDRR transmission line, because its conductor diameter (d°) and height (h°) is constant per unit length and thus gives constant L to C per unit length. Just looking at the vertical post we see this cannot be the case for a cylindrical conductor mounted vertical to a flat ground plane. Anyone can see that if we sawed out a given width slice from the vertical post conductor at a height of, say, ¼ inch above ground, and measured the shunt capacity of this insulated section to ground there, and then repeated the same procedure at a height of 36 inches above ground, and then at 72 inches above ground, shunt capacity would be maximum at ¼ inch above ground, less at 36 inches, and least at a height of 72 inches. Because shunt C varies with length h°, the ratio of L/C cannot possibly be constant; therefore, the "characteristic impedance" of the vertical post – when considered as an rf transmission line – would have to be a variable function of height h°. At the same time you have a suspicion that the vertical post in the DDRR is something more than just a "shorting post." A grounded, vertical monopole antenna, maybe?? You may wonder what we are up to here.

Well, you are perfectly right. Not only does the characteristic impedance of the vertical post rf transmission line change with height, but it is also a grounded, vertical monopole antenna. How do you find the "characteristic impedance" of a monopole antenna? Well, thanks to a brilliant antenna man, Dr. S. A. Schelkunoff of the Bell Telephone Laboratories,[2] we can do just that:

$$K_m = 60 \left[2.3026 \log_{10} \frac{2(h)}{a} \quad 1.0 \right] \text{ Ohms} \qquad (1\text{-}2.0)$$

The above equation gives the *average* characteristic

[2] S. A. Schelkunoff, "Antennas of Arbitrary Size and Shape," Proc. I.R.E., *29,* 493-521 (September, 1941).

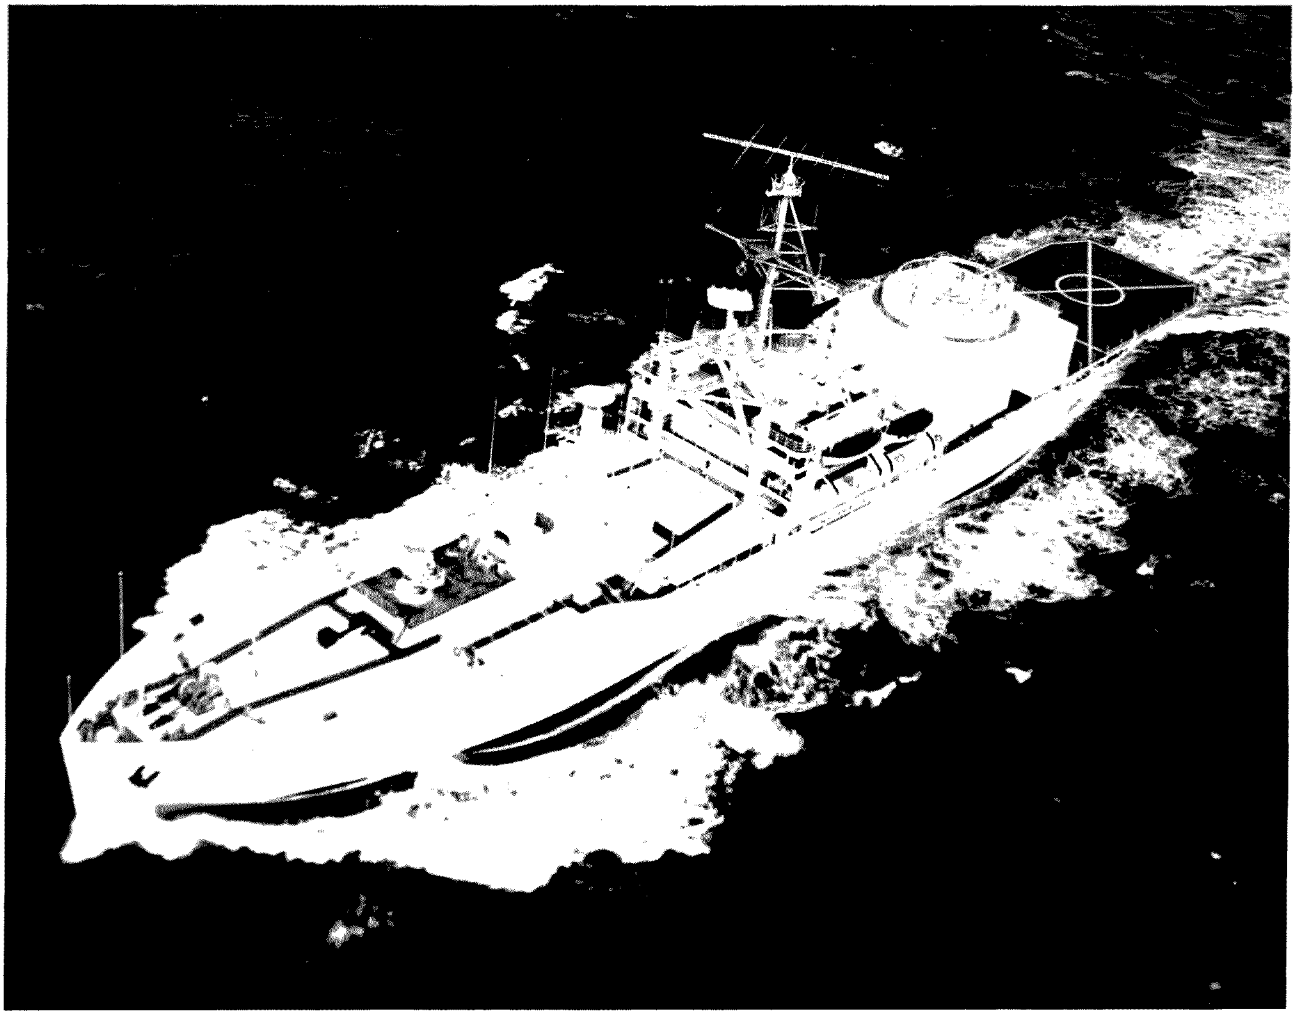

Fig. 2. The DDRR antenna is shown here installed aboard the U.S. Navy communications ship U.S.S. Wheeling. *The antenna is seen mounted aft on the roof of the helicopter hangar. Operating efficiently even though exposed to the weather, the antenna was later covered with a pillbox fiberglass radome housing (official U.S. Navy photograph).*

impedance[3] of a cylindrical vertical conductor monopole antenna over ground having a conductor radius "a" and length h. It is an average value because of the variable nature of the post monopole antenna's characteristic impedance with length h. Schelkunoff's equation (1-2.0) looks so simple in form and very similar to (1-1.0), yet it is loaded with electromagnetic dynamite! We will discuss just how in Part II. Here we can honestly say that, aside from Ohm's Law, this simple little formula may become one of the most useful expressions known to the ham fraternity for getting quick and easy *practical* answers to real antenna problems of all kinds. Oh yes, if you multiply the answer you get from (1-2.0) by two, it gives the average characteristic impedance (K_a) of a balanced *doublet antenna* in *free space* of total length (2 h) formed from two identical "monopoles" of length h and cylindrical conductor radii "a".

[3]The symbols K_c and K_m are used to denote the characteristic impedance of the horizontal and vertical monopole antenna transmission lines, respectively, instead of Z_o, in order to avoid getting these values confused with the Z_o of the standard transmission line we will use to feed the DDRR antenna.

Tuning the DDRR

Armed with the simple formula (1-1.0) and the seemingly simple equation (1-2.0), we are fully equipped now to move on to design our DDRR for resonance and tuning over the width of the entire 75 meter band (or a bit more). Turning to Fig. 3(c), the DDRR antenna is now illustrated as being an antenna system composed of *two* distinct rf transmission lines, one connected to the other. Please do not let the drawing fool you. The first transmission line section, of electrical length h° and characteristic impedance K_m, shown "lying over on its side" still represents the vertical post of the DDRR antenna. It is just easier to indicate the post in this way when it is represented as an rf transmission line. In our "model" drawing of the DDRR antenna system of "open wire" lines, we have two terminals to represent the ground plane end of the post; terminal 1G is ground at a point where the base end terminal (1A) of the post connects to it. At a distance of h° away from the post base, the *top end* of the monopole transmission line has a second terminal (2A). However, "ground" is now labeled 2G, and represents a *circle* drawn *on the ground*

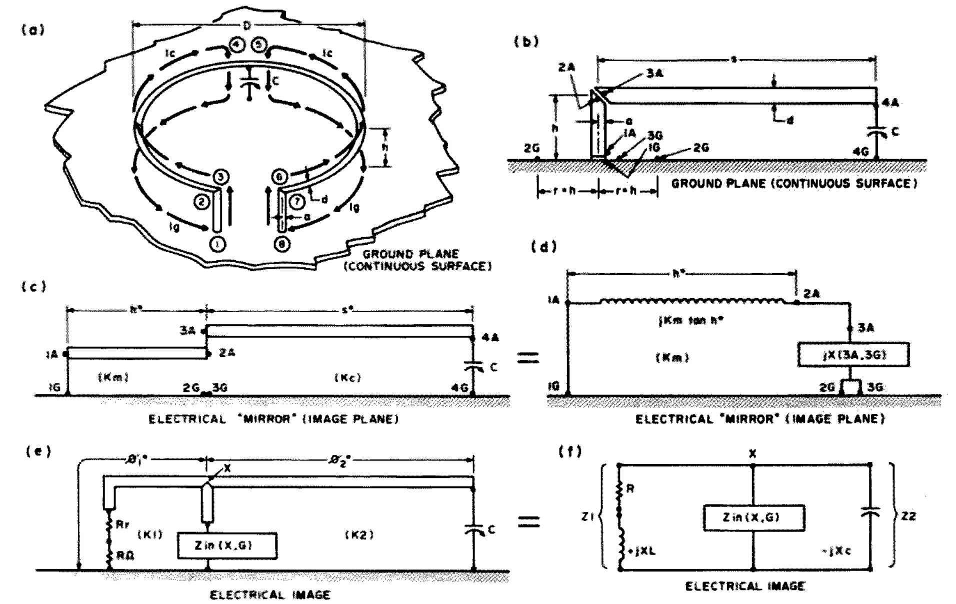

Fig. 3. (a) Wheeling-*type two post DDRR over metal sheet ground plane, showing current flow in elements and ground. (b) Half circumferential section of two post DDRR in linear alignment. (c) Design schematic of vertical post monopole transmission line "terminated" into horizontal transmission line section. (d) Equivalent circuit of monopole transmission line antenna loaded by top reactance. (e) Diagram for matching feed transmission line to the DDRR antenna. (f) Equivalent circuit of input impedance at feedpoint X.*

plane surface with a radius h°, the center of this circle being the post base (a little weird, perhaps, but we need imagination in dealing with antennas!). Then the end of the horizontal line conductor, at the point where it conductively joins the top of the vertical post terminal (2A), is labeled 3A. At a *point* on the ground plane directly below terminal 3A, a ground terminal (3G) is shown. At horizontal distance S° away on the transmission line, of characteristic impedance K_c and at a constant height (h°), the other end of this second transmission line conductor is labeled 4A. Again, directly below terminal 4A, a point on the ground plane forms the terminal 4G. The tuning condenser (C) is connected across terminals 4A and 4G of the horizontal rf transmission line.

Using equation (1-2.0), we can now find the average K_m of the particular vertical post of length h° = 8.78° and conductor radius "a°" = 0.24° we have chosen:

$$K_m = 60\left[2.3026\ \frac{2(8.78°)}{0.24°}\ 1.0\right] = 60\ (3.29) =$$

$$197.57 \text{ Ohms}$$

Now let us imagine that in some way rf energy at 4.0 MHz is fed to our system of two rf transmission lines. As the two lines are *not* terminated into resistive "loads" equal to K_m and K_c respectively, these two rf lines are badly mismatched in impedance; they will act like what we call transmission line "stubs," and establish large amplitude standing waves along their respective lengths. For the moment, let's assume condenser C is either absent or set to an impossible minimum capacity of zero farads. For that condition, a reactive "load" $jX_{in}(3A,3G)$ produced by the horizontal line section of length S° will be "seen" across the "output" terminals 2A,2G of the vertical post transmission line. Because capacity C is absent, and we are temporarily ignoring things such as antenna radiation resistance R_r, we can describe the value of $jX_{in}(3A,3G)$ Ohms which will be "seen" by the vertical post line as a "load" across its output (top end) terminals. See Fig. 3(d). It is

$$jX(3A,3G) = -jK_c \text{ cotan } S° \text{ Ohms}$$

$$(1\text{-}3.0)$$

Because we are temporarily saying that our antenna possesses no resistance or "real" impedance terms, $jX(3A,3G)$ will be a pure reactance. Because the vertical post is now acting like an rf transmission line of length h°, the "load" $jX(3A,3G)$ across its output terminals 2A,2G will become *changed* in value as it "moves" or is transformed down the length h° of the post line to its own "input terminals" 1A,1G. This change or transformation property of rf transmission lines is compactly represented by the well-known terminated transmission line equation:

$$jX_{in}(\ ) = K\ \frac{(jX(\ ))\cos\phi° + jK\sin\phi°}{K\cos\phi° + (jX(\ ))\sin\phi°}$$

$$(1\text{-}4.0)$$

Equation (1-4.0) is written in a form suitable only for lines terminated in a pure reactance load jX(). The symbol K denotes the characteristic impedance of the transmission line and $\phi°$, its length. So here is our DDRR design "law" number 1.0:

"For the vertical post monopole antenna of electrically small length h° to become resonant at a given frequency of operation f_o, the load reactance $jX(3A,3G)$ Ohms placed across its top and ground must be precisely of the correct value so as to change in reactance to the value $jX_{in}(1A,1G)$ = j0 Ohms at the *base of the monopole* where it joins the ground plane."

It turns out that if, and only if, you require $jX_{in}()$ from equation (1-4.0) to equal j zero Ohms, you *needn't solve it completely.* All you have to do is to plug in a load impedance jX() which, when multiplied by the cosine of the line electrical length $\phi°$, makes the algebraic sum in the numerator equal to zero. For that condition, $jX_{in}()$ has to go to zero Ohms. Nature is kind to us here. It turns out that if

$$-jK_c \text{ cotan } S° = -(jK_m \tan h°)$$

$$(1\text{-}5.0)$$

the algebraic sum of (jX()) cos h° plus jK_m sin h° will add up to zero Ohms, making $jX_{in}()$ go to zero Ohms and the post monopole resonant at f_o. Remember, however, that $-jK_c$ cotan S° only equals $jX(3A,3G)$ when tuning capacity C is equal to zero farads. For this case of C equals zero farads, already knowing K_c, K_m and h°, we get:

$$-jK_c \text{ cotan } S° = -(j197.57 \tan 8.78°) = -j30.51 \text{ Ohms}$$

$$(\text{eq } 1\text{-}6.0)$$

Then, knowing K_c, we rearrange (1-5.0) to find how long in electrical degrees S° has to be in the horizontal line to make (1-5.0) true (with all the little j operators and signs canceling out):

$$\cot S^\circ = \frac{K_m \tan h^\circ}{K_c}$$

(1-4.1)

For our particular DDRR, we find that the electrical length of the horizontal transmission line (with no tuning capacitor) must be:

$$\cot S^\circ = \frac{30.51}{256.70} = 0.1188$$

or,

$$\cot^{-1} 0.1188 = 83.22^\circ = S^\circ$$

Plugging our obtained value of S° back into (1-3.0), we can prove that $jX_{(3A,3G)}$ = -j 256.70 cotan 83.22° = -j 30.52 Ohms.

The answer is not precisely equal to $-(jK_m \tan 8.78^\circ)$ because we have not been using enough decimal places to make equality exact. Still, we are now resonant at 4.0 MHz if we place a load reactance of -j30.52 Ohms across the top and ground "circle" terminal 2G of the monopole. But wait a minute! You can't buy a tuning condenser which has a zero farads minimum capacity when tuned with its plates wide open! OK — we just look at the label on the box it came in and find the minimum capacity of our condenser. Say it is C_{min} equals 8.0 picofarads. Here is the question we must ask ourselves: How much "electrical length" at 4.0 MHz does a 8×10^{-12} farad condenser, connected across the end terminals 4A,4G of a line of K_c = 256.70 Ohms, add to that already existing in the line? Now, at 4.0 MHz, an 8.0 $\times 10^{-2}$ condenser offers a reactance $-jX_c = -j\,(\frac{1}{2\pi}\, 4.0 \times 10^6 \times 8.0 \times 10^{-12})$ = -j 4,973.60 Ohms. Say we call the length *added by the condenser* ΔS°. Then,

$$\cot \Delta S^\circ = \frac{X_c}{K_c} = \frac{4{,}973.60}{256.70} = 19.331$$

$$\cot^{-1} 19.331 = 2.96^\circ = \Delta S^\circ$$

(1-6.0)

To correct the length of the horizontal transmission line to compensate for the effect of the "line stretcher" action of C when tuned wide open at the high frequency end of the band, we merely remove 2.96 degrees from the conductor so that our horizontal transmission line *itself* becomes

$$83.22^\circ - 2.96^\circ = 80.26 \text{ degrees}$$

The electrical length of the line itself, and the additional electrical line length added by the minimum capacity of C, now sum up to the necessary 83.22 degrees. In addition, to also take into account other small capacity from the leads to the condenser, another four inches or so (about 0.5°) should be removed to make *sure* we reach 4.0 MHz with C wide open. Right here we will continue to use, however, an actual horizontal transmission line length of 80.26 degrees in completing the DDRR design.

Our "paper" DDRR antenna element now is resonant at the 75 meter high frequency limit of 4.0 MHz. Once in a while we like to spin the rig down to 3.5 MHz (well, 3.499 MHz maybe) and do a little brass pounding and DX hunting. When the frequency of the DDRR is changed from 4.0 to 3.5 MHz, this represents a proportionality factor of 3.5 MHz/4.0 MHz equals 0.875. All the DDRR electrical length parameters will change by such proportionality. For example, the vertical post height will change to h°(3.5 MHz) = 8.78° x 0.875 = 7.68°. The actual line length S° will become S°(3.5 MHz) = 80.26° x 0.875 = 70.23°. We immediately suspect, without having to solve equations (1-3.0) and (1-5.0), that $-jK_c$ cotan 70.23° no longer will be equal to $-(jK_m \tan 7.68^\circ)$. We just *know* that now the DDRR antenna is far out of resonance at 3.5 MHz. However, having seen how the tuning condenser C can act like a "line stretcher," we know how to solve our problem. We first ask, "What load reactance $jX_{(3A,3G)}$ do we now need across the end terminals 2A,2G of the monopole transmission line at 3.5 MHz?" Equation (1-5.0) answers:

$$jX_{(3A,3G)} = -jK_c \cot S^\circ = -(j\,197.57 \tan 7.68^\circ) = -j\,26.64 \text{ Ohms}$$

Second question: "How long would S° have to be at 3.5 MHz to give $jX_{(3A,3G)}$ = -j 26.64 Ohms *if capacity C was absent?*" Equation (1-5.1) answers:

$$\cot S^\circ_{(3.5\text{ MHz})} = \frac{26.64}{256.7} = 0.104;\quad S^\circ_{(3.5\text{ MHz})} = 84.075^\circ$$

We require a total electrical line length S° of 84.075 degrees, but we already have an existing transmission line length of 70.23 degrees at 3.5 MHz. Therefore, we are 84.075°-70.23° = 13.845 degrees *too short.* Final question: "If we meshed in the variable plates of condenser C to make its capacity larger in value, how much capacitive reactance $-jX_c$ would we need to 'stretch' our 70.23 degree horizontal transmission line out to a total of 84.075 effective electrical degrees?" Now, if we look at equation (1-6.0) we see it can be rewritten to solve for X_c when ΔS° and K_c are given. We know K_c, and ΔS° is just our needed extra length of 13.845 degrees. Therefore,

$$X_c = (\cot \Delta S^\circ)\, K_c = (\cot 13.845^\circ)\, 256.70 \text{ Ohms}$$
$$X_c = (4.058)\, 256.70 = 1{,}041.56 \text{ Ohms}$$

To obtain 1,041.56 Ohms of capacitive reactance at 3.5 MHz, we will need a condenser capacity of $\frac{1}{2\pi}$ 3.5 x 10^6 x 1,041.56 = 43.66 x 10^{-12} farads. Of course, the nearest standard tuning capacitor size to 43.66 picofarads is fifty picofarads. The remaining capacity in the variable tuning condenser would permit us to tune down a *bit below* 3.5 MHz, either to listen around or transmit if we had some legal reason (MARS?) to do so. As the DDRR antenna is electrically small, there will be quite a respectable voltage drop across the tuning condenser C. Use 10 kV per 1.0 kW of *peak* input power to the antenna to obtain a decent safety factor to prevent condenser flash-over on modulation peaks. Readers will see that if we kept adding capacity C, the 75 meter band DDRR could be pushed on down to the 160 meter band and even into the standard BC frequency assignments. Please don't try to do this! A *bit* below 3.5 MHz is fine. When you add more tuning capacity to the DDRR to stretch tuning too far, a number of undesirable things begin to happen to lower efficiency. We have an optimum design up to here. Don't ruin it, please. If you need 160 meter coverage, design a separate 160 meter band element according to the relations given here for 75 meters. In Part II we will tell how to combine the elements into a single allband DDRR which can hop from one band to the next like a jackrabbit.

Matching the DDRR

In Fig. 3(e) the DDRR transmission line section is shown, still in "straightened out" form. Although we do not yet know the values of radiation resistance R_r and the environmental ohmic loss resistance R_Ω, these two "resistors" are shown schematically connected in series between the base terminal 1A of the vertical post and ground 1G. In antenna theory, radiation resistance R_r is always referred, by convention, to a current maximum point in an antenna. Although "referred" to this point, however, the total resistance $R_t = R_r + R_\Omega$ may be "transformed" to any other point X on the antenna, just as our top load reactance $jX_{(3A,3G)}$ was transformed to the base terminals 1A,1G of the monopole. That, however, was a "movement" along the line length in the *opposite* direction. We also recall that when tuning capacitor C made $jX_{(3A,3G)}$ correct in value, it transformed along the length h° of

the vertical post transmission line and became zero reactance at its base. The radiation resistance magnitude of an electrically small antenna is not large. By design, we also go all out to keep the ohmic loss resistance R_Ω small in value.

Now, if we tried to conventionally feed the DDRR in series with the vertical post base, we would face the very severe problem of making an impedance match between this very small value of *resonant* input impedance $Z_{in}(1A,1G) = R_r + R_\Omega + j0$ Ohms there and the characteristic impedance Z_0 of our standard feedline. To achieve such match would require an *auxiliary* impedance matching transformer which would *also* have to be *tuned in track* with C when we changed frequency. To avoid this needless difficulty and technical messiness, we use the DDRR antenna itself as an impedance step-up transformer, so that we can connect the standard feed transmission line directly to the DDRR antenna at some conductor point X to obtain a low vswr match. It was said a while back that the DDRR is just a system of open wire, transmission line "stubs." There is a really wonderful thing about a resonant transmission line stub: At resonance, no matter at which point along its conductors you measure impedance, it always is found to be a *pure resistance.* If one end of a "one wire" line stub is "shorted," and you measure between the conductor point X and ground, you get an input impedance,

$$Z_{in}(X,G) = \frac{Z_1 \times Z_2}{Z_1 + Z_2} \tag{1-7.0}$$

This input impedance is schematically shown in Fig. 3(f), where in equation (1-7.0)

$$Z_1 = K_1 \frac{(R_t + j0)\cos\phi_1^\circ + jK_1 \sin\phi_1^\circ}{K_1 \cos\phi_1^\circ + j(R_t + j0)\sin\phi_1^\circ}$$

$$Z_2 = K_2 \frac{(0 + jX_c)\cos\phi_2^\circ + jK_2 \sin\phi_2^\circ}{K_2 \cos\phi_2^\circ + j(X_c)\sin\phi_2^\circ}$$

K_1 is the characteristic impedance of the transmission line section to the *left* of point X of electrical length ϕ_1 degrees; and K_2 is the characteristic impedance of the transmission line section to the *right* of point X of electrical length ϕ_2 degrees; and $R_t = R_r + R_\Omega$; and X_c is the reactance of tuning condenser C at frequency f_0.

The great thing is that in practical design of a DDRR you don't have to bother to solve equation (1-7.0), nor do you have to have a nice but expensive Z bridge in order to make a low vswr impedance match to the DDRR in finding point X. This is because, when you design your DDRR antenna element section as given here and adjust condenser C to produce resonance at the operating frequency f_0, all shunt reactance at point X and ground goes to zero, leaving only a resistive value of input impedance. What you do instead is this: (a) carefully grid dip your new DDRR (loose coupling to the post base) to an f_0 close to the *middle* of the ham band; (b) put the rig on low power or "tune" so that it feeds a signal at f_0 into the coax leading out to the DDRR; (c) connect a vswr meter in series with the end of the coax close to the DDRR where you can read the instrument; (d) connect the shield braid of the coax on the other side of the vswr meter to a *temporary* ground point; and (e) starting at a point X a little way up the *vertical post,* tap the inner conductor of the coax to successively higher points X until vswr falls to 1.0:1 at f_0.

A few words of fraternal advice, however:

(1) Make your grid dip reading to f_0 while adjusting C to get resonance *without the coax feed connected to the DDRR;* otherwise, you will get a false reading.

(2) When you then connect the coax in shunt across point X and ground you will disturb the DDRR's near-zone field and the resonance will shift frequency. That doesn't matter: With the rig *still on f_0,* "tweak" the tuning condenser CCW or CW until you find the point of *minimum* vswr at that point X on the antenna. If the *minimum* vswr found by careful adjustment of C is higher than 1.0:1, shift to a higher point X on the antenna and repeat the "tweaking" process. When you find the *midband* frequency point X where adjustment of C gives a minimum vswr of 1.0:1, you will find that this *same fixed point* X will yield a vswr of less than 2:1 when the DDRR is tuned anywhere in the band (or a bit more). The final point X, found for 1.0:1 vswr in the middle of the band, *may* end up either on the vertical feed post *or* out on the conductor of the horizontal transmission line section; its exact location is determined by h° and K_m. The larger h° is and the lower K_m is, the *lower on the antenna* the 1.0:1 vswr point X will be found. Lastly, you will be bothered by the fact that the DDRR tuning is very touchy and that the presence of your body near the antenna affects tuning. This happens in all electrically small antennas of *high* efficiency. When you actually match your finished DDRR it will be in a different shape and have a remotely driven tuning condenser, and there will be no ordinary kind of metal sheet or radial wire ground plane beneath it. You will be able to mount it on the wooden garage roof or rest it on coke bottles over the bare ground. After giving last touches to the ham band DDRR, we will go on to describe some other electrically small, transmission line antennas which we hope you will find both interesting and useful. Because of your briefing on the DDRR, understanding these other antennas will be mere child's play. ■

Fig. 1. MINI-MOS electronic keyer with dual paddle key. The transistor battery in the foreground not only shows the size of the keyer, but can also power the keyer for over one year of daily operation.

MINI-MOS-- The Best Keyer Yet?

--nothing Mickey Mouse about this one

Some time ago, when my code speed had gradually crept up to 16 wpm, I felt ready to trade my straight key for something more advanced. A "COSMOS IC electronic keyer," described in an article by WB2DFA[1] seemed to be a good choice. The keyer was built and seemed to perform fine. In due time, however, some limitations were found, which unfortunately proved to be inherent to the design approach chosen by WB2DFA:

- The keyer did not have a dot memory. This makes it necessary to move the keyer paddle exactly in the right rhythm; otherwise one can easily lose dots, especially in letters like K, C and Y.
- The keyer used a continuously running clock. When the dot or dash contact is closed, the keyer has to wait for the next clock pulse before the code element is sent. This is especially noticeable at low code speeds.
- The keyer drew very little current and was, therefore, operated from a 9 volt transistor battery. Theoretically the battery should give over 200 hours of operation. If one forgets to turn off the keyer, however, it does not last very long.

At a local hamfest I had a chance to compare several commercially manufactured keyers, including some that had dot and dash memory and iambic keying. After this experience I was no longer satisfied with my old keyer and decided to design a better one. My keyer was to incorporate the features available

in the best commercial keyers, but would also fully utilize the advantages of complementary MOS technology.

The result of this design project was the MINI-MOS keyer shown in Fig. 1, which has now been in use for over one year. This keyer has the following features:

- Dot and dash memory and gated clock.
- Iambic operation when used with a double ("squeeze") paddle.
- Extremely low standby current, which makes it unnecessary to provide an on-off switch.
- Low "key down" current, which makes it possible to operate the keyer from a normal 9 volt transistor battery for at least one year.
- Low component count (7 ICs and few discrete components).
- Built-in sidetone oscillator with speaker and keying circuit for grid-block keyed transmitter.

The completed keyer is very compact and can be packaged in a minibox measuring only 2 by 2 by 4 inches, including batteries and sidetone speaker. Together with a small dual paddle, the keyer was mounted on a base only 4 by 4 inches in size.

Circuit Description

The keyer utilizes the "complementary metal oxide silicon" or CMOS technology. Digital integrated circuits based on this technology were first introduced by RCA as the CD4000 series, which is now also available from several other manufacturers. While normally the acronym CMOS is used for the technology, RCA favors the term COS/MOS. Another family of CMOS ICs is the 74C series, which is pin compatible with the well-known 7400/5400 TTL series. Until not too long ago, CMOS ICs were a rarity on the surplus market and, if available, were much more expensive than comparable TTL ICs. But today CMOS ICs are available from many mail order suppliers. While prices have come down substantially, they still can differ a lot between dealers and it pays to compare advertisements. Because the CD4000 series seems to be available more readily than the 74C series, it was used in the design of the MINI-MOS keyer.

The operation of the keyer circuit will be described using the "positive logic" convention. This simply means that when the voltage at a certain point in the circuit is "high" (close to the positive supply voltage VDD), it will be assigned a logical "1." Conversely, the logical "0" corresponds to a "low" voltage (close to the negative supply voltage VSS).

Fig. 2 shows the circuit diagram of the keyer and lists the parts used. The dot and dash contacts of the keyer paddles are connected to two RS (reset-set) flip flops which serve as memories for the entered code elements. These flip flops are made up from four NAND gates contained in IC U1. One of the flip flops is redrawn in Fig. 3, which also shows the so-called "truth table" of the circuit. This table simply indicates the voltages at the outputs Q and $\bar{Q}$ of the circuit for the four possible combinations of input voltages. While these flip flops store the entered dot or dash, the code element currently being sent is stored in one of the two flip flops U3A and U3B. These flip flops are of the D (data) type and can be set and reset in two different ways. A logical 1 at the S or R input of the flip flop will set or reset it asynchronously – that is, at the instant the voltage goes from low to high. The flip flop can also be set by a logical 1 and reset by a logical 0 applied to the D input. This, however, occurs synchronously with a clock signal applied to the C (clock) input and at the instant this signal makes a transition from high to low.

When the keyer is in standby (that means if no code element is currently being sent), dot flip flop U3A as well as dash flip flop U3B are in the reset position and both their $\bar{Q}$s will be high. In this case the output of AND gate U4A is also high. This output is connected to one input of the AND gates U2B and U2D. This has the effect that the output of the dot memory is connected to the S input of dot flip flop U3A, while the output of the dash memory is connected to the S input of dash memory U3B. One input of NOR gate U7A also receives a high signal which stops the clock.

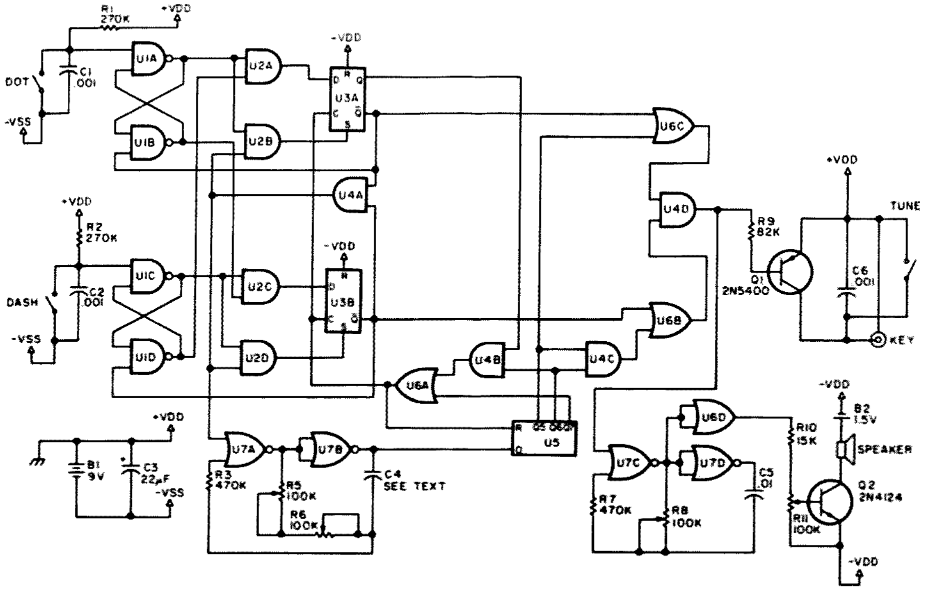

Fig. 2. Circuit diagram of the MINI-MOS keyer. Parts list: U1 – 4011 quadruple 2-input NAND; U2, U4 – 4081 quadruple 2-input AND; U3 – 4013 dual D-type flip flop; U5 – 4024 7-stage binary counter; U6 – 4071 quadruple 2-input OR; U7 – 4001 quadruple 2-input NOR; Q1 – 2N5400 or other small signal PNP transistor with a voltage rating sufficient for the keying voltage of the transmitter; Q2 – 2N4142 or most any other small signal NPN silicon transistor; R5, R11 – miniature potentiometers, 100k Ohm linear taper; R6, R8 – trimpots, one turn, 100k Ohm; C4 – see text; C3 – 22 microfarad, 15 volts; B1 – standard 9 volt transistor battery; B2 – AA cell, regular or alkaline type; SP – miniature speaker, 2 inch diameter (Radio Shack or other).

Fig. 3. Reset-set (RS) type flip flop made up from NAND gates. The "truth table" shows the relation between signals at the inputs and outputs of the circuit.

	A	B	Q	$\bar{Q}$
SET	0	1	1	0
RESET	1	0	0	1
STORE	1	1	x	$\bar{x}$
AMBIGUOUS	0	0	1	1

Now, when either the dot or the dash contact is closed, causing a logical 0 at the set input of the dot or dash memory, the Q output of this memory flip flop will go high. This in turn causes the corresponding D flip flop to be set instantaneously via its S input. When the D flip flop is set, its $\bar{Q}$ output goes low. This causes the appropriate memory flip flop to be reset at the instant the dot or dash contact is opened again. The logical 0 at the $\bar{Q}$ output of the D flip flop, via AND gate U4A, also disconnects both memory flip flops from the S input of their associated D flip flop. At the same time the clock is started.

The D flip flops now operate in the synchronous mode and can change their state only when a negative going transition occurs at their C inputs. Let us assume that the dot flip flop U3A has been set in this way, and examine what happens when a negative transition occurs at the C inputs of U3A and U3B. There are actually four different possibilities:

1. The dot contact has been opened and the dot memory has been reset. The dash memory has not been set. This results in a low signal at the D input of U3A. When the clock signal goes low, this flip flop will therefore be reset and the circuit returns to the standby status.

2. The dot contact is still closed and the dot memory, therefore, has not been reset. This causes a high signal at the D input of U3A. This flip flop thus does not change its state when the clock signal goes low, which results in another dot being sent.

3. The dot contact has been opened and the dot memory has been reset, but the dash contact has been closed, setting the dash memory. This results in a low signal at the D input of U3A and a high signal at the D input of U3B. When the clock signal goes low, U3B will be set, while simultaneously U3A is reset. Thus a dash will be sent following the dot.

4. Both the dot and the dash contact are closed and both memory flip flops are therefore in the set position. This would place a logical 1 at the D inputs of both U3A and U3B, were it not for the iambic gates U2A and U2C. These gates have one of their inputs connected to the $\bar{Q}$ output of the "opposite" memory flip flop. Because the dash memory is in the set position, its $\bar{Q}$ output is low. Via U2A this results in a low signal at the D input of U3A. The dot memory is also in the set position, but U3A is trying to reset it. As can be seen from the truth table in Fig. 3, this causes both outputs of the memory flip flop to go high. Via U2C this results in a high signal at the D input of U3B. When the clock signal goes low, this causes U3A to be reset and U3B to be set. If the dot and dash contacts continue to be closed, the process will be reversed the next time the clock signal goes low. The keyer, therefore, will send dots and dashes alternately in the so-called iambic mode until one or both key contacts are opened. (The word iambic, incidentally, comes from the iamb or iambus, a Greek verse in which long and short syllables alternate.)

U3A remains in the set position while a dot is being sent, as well as for the space that follows. The clock pulse to reset U3A, therefore, has to occur two dot elements after the flip flop has been set. The clock pulse for resetting the dash flip flop U3B has to come 4 dot elements after it has been set. In order to obtain the spaces after the dot and dash, pulses after 1 and after 3 dot elements are also required. These pulses are obtained from the clock through a pulse divider. The clock consists of the NAND gates U7A and U7B, which are connected as a free running, gated multivibrator[2,3]. This circuit is amazingly stable, and a variation of the supply voltage between 6 and 10 volts causes a frequency shift of only about 1%. The square wave at the output of the multivibrator is not completely symmetrical, however, and the first period after being gated on may have a slightly different length than the following periods. In order to avoid timing errors, the clock signal was not used directly, but was divided in a frequency divider. The IC U5 very conveniently contains not fewer than seven flip flops which are connected as a seven stage binary counter. The output of the fifth stage, Q5, goes high after 2^4 or 16 input pulses, and goes low again after 2^5 or 32 input pulses. This output is used to represent one dot element. Similarly, the output of the sixth binary stage, Q6, represents two dot elements, and the output of the seventh stage, Q7, four dot elements. A signal representing three dot elements is obtained by connecting Q5 and Q6 to the inputs of AND gate U4C. A reset pulse after 2 dot elements must occur only if a dot is being sent, that is, if U3A is in the set position. Output Q of U3A is therefore used to gate output Q6 via AND gate U4B. If U3A is not in the set position, the reset pulse comes from output Q7 and occurs after 4 dot elements. OR gate U6A is used to combine the two reset pulses. The output of this gate not only provides the clock pulse for the two D flip flops, but also resets the binary counting stages of U5. As a matter of fact, when Q6 or Q7 goes high and applies a high signal to the R input of U5, resetting the binary stages causes the output to immediately go low again. The clock pulse, therefore, is only about one microsecond long.

Most modern transmitters and transceivers use grid block keying and their keying input carries a negative voltage of somewhere between 50 and 150 volts with respect to ground. On "key down," the key has to sink a current of a few milliamperes. This voltage can easily be keyed with a PNP

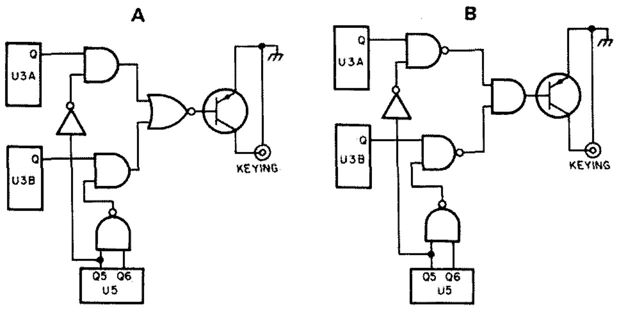

Fig. 4. a. First design of the keying section. b. DeMorgan's theorem (see text) applied to the NOR gate.

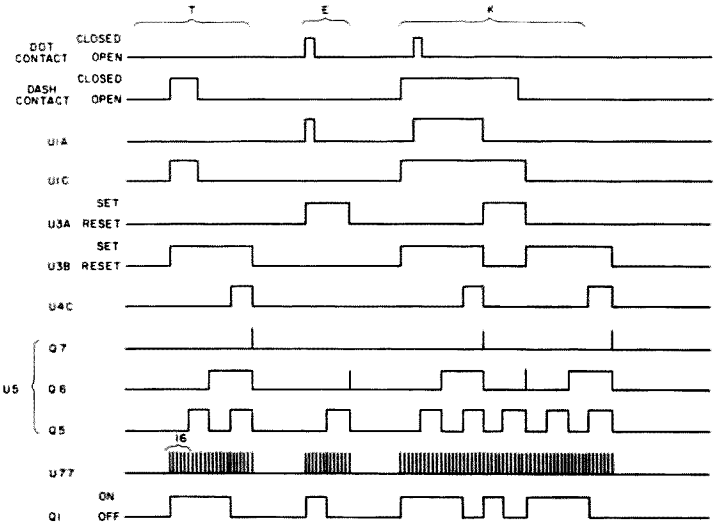

Fig. 5. Pulse diagram showing the signals at different points of the circuit when the letters "-T-E-K-" are being sent.

transistor of sufficiently high voltage rating. The emitter of this transistor has to be connected to the +VDD voltage of the CMOS circuit. The transistor is turned on by a logical 0 at its base.

The initial design of the keying section is shown in Fig. 4a. The two AND gates together with the inverter and NAND gate are used to turn the keying signal off during the last dot element of a keying cycle, thus providing the space after the dot or dash. The circuit in this form, however, does not utilize efficiently the gates that are left over from the timing section of the keyer. The circuit of Fig. 4a was therefore modified using a rule known as the DeMorgan theorem (named after a 19th century British mathematician). This rule simply states that a gate can be replaced by its opposite type (AND with OR or OR with AND) if inputs and output of the gate are inverted. If this rule is applied to the NOR gate of Fig. 4a, the circuit of Fig. 4b is obtained. If the rule is applied a second time, this time to the two NAND gates of Fig. 4b, the final circuit shown in Fig. 2 results, which utilizes the available gates much more efficiently than the initial design.

The sidetone oscillator was built from the remaining two NOR gates (U7C and U7D), using the same circuit as for the clock. One OR gate, U6D, which was left over, was put to good use as a buffer to make the frequency of the sidetone oscillator independent of the sidetone volume. U6D has to be connected to the output of U7C, which is low during standby to keep current from flowing during the standby mode. The sidetone signal is applied to the base of transistor Q2, which is driven in class C mode. When volume control R11 is completely counterclockwise, Q2 remains cut off and no separate on-off switch for the sidetone is necessary. The power for the speaker is supplied by a separate battery (one AA cell). This was found to be simpler than providing an output transformer for the speaker.

The keying transistor, Q1, is rated for a maximum collector-emitter voltage of -120 volts. Its current sinking capability is determined by the resistance of R9. With the value given in Fig. 2, the keyer can sink currents of up to 4 milliamperes even when the battery voltage has dropped to 6 volts.

For use with a cathode- or emitter-keyed transmitter, Q1 can be used to drive an NPN transistor with a voltage and current rating sufficient to key the transmitter. In this case R9 has to be chosen so that the NPN transistor saturates safely on "key down." The MINI-MOS keyer also will have to be grounded at the -VSS rather than the +VDD side of the battery. This modification, however, is likely to increase the current drain on the battery.

In order to show how the different parts of the MINI-MOS keyer circuit work together, a timing diagram is given in Fig. 5. This diagram shows the voltages at various points of the circuit when the letters "-T-E-K-" are being sent. For the letter K, which has been shown as being sent in the iambic mode, the function of the dot and dash memories can easily be seen.

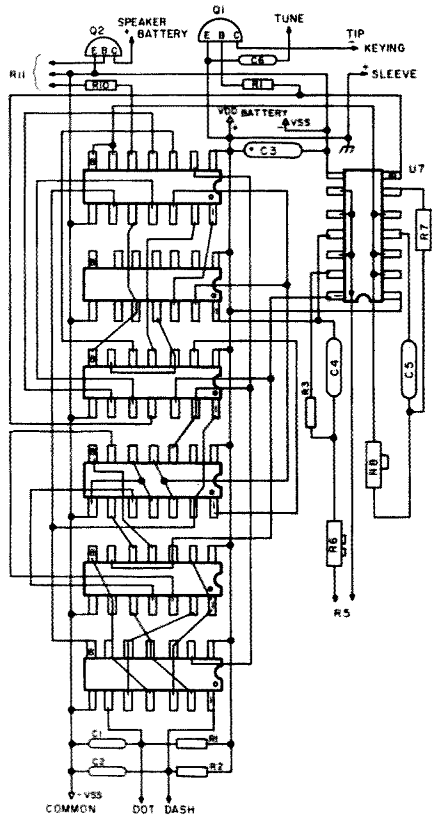

Fig. 6. Wiring diagram of the MINI-MOS keyer. View is at the pins *of the integrated circuits.*

Construction of the Keyer

It is much easier to build the MINI-MOS keyer than to

understand the functioning of its circuit. The circuit was assembled on a small piece of perforated circuit board. The wiring was done with #24 bus wire, using spaghetti tubing (preferably teflon) as insulation at the points of wire crossing. All that is necessary for this technique is a small soldering iron, tweezers, a steady hand, and – if one is over 40 – a good watchmaker loupe. Long wire runs, like the supply buses, were "woven" through the holes of the circuit board to stabilize the wire in order to prevent shorts. From previous experience, however, it was found advisable to work from a wiring diagram in order to prevent errors. This wiring diagram is shown in Fig. 6. (It would be a service to mankind if some fellow ham experienced in the fine art of PCB layout would convert Fig. 6 into a printed circuit board.) A view of the completed circuit board, mounted in the minibox together with the other components, is shown in Fig. 7.

It might be worth mentioning that the circuit was first assembled on one of the plug-in boards available for the breadboarding of IC circuits. In transferring the breadboard to the final circuit board, an unusual problem was encountered: The circuit did not work, because the pinout diagram for the CD4013 in the RCA databook (1975 edition) contained an error (Fig. 6, however, shows the correct connection).

The keyer has only three external controls: adjustments for code speed (R5) and sidetone volume (R11), and the tuning button, which was mounted on top of the minibox. Trimpots, accessible through holes, allow setting of the sidetone frequency (R8) and the maximum code speed (R6). The minimum code speed is determined by C4. When a .05 microfarad capacitor is used, the slowest code speed is about 5 wpm, while a .025 microfarad capacitor results in a minimum speed of about 10 wpm. These capacitors should be of the mylar type in order to avoid frequency changes with changing temperatures. Because of the stability of the clock circuit, it is actually possible to calibrate R5 directly in wpm, which should be of interest if the keyer is used to send code practice lessons. The standard code speed, as it is used for the FCC code test, is based on words exactly 50 dot elements long (the reference word is "Paris"). Because 16 pulses at the output of the master clock (U7B) correspond to one dot element, the code speed can be calibrated by measuring the clock frequency. If available, a counter can be used for this purpose; otherwise, the frequency can be beat against an audio oscillator. A code speed of "X" wpm corresponds to a clock frequency of X times 13.3 Hz. Thus a code speed of, for instance 20 wpm, is sent when the clock is set to a frequency of 266 Hz.

The standby current drawn by the circuit is less than 1 microampere. In the standby mode the life of the battery, therefore, is actually determined by its shelf life. On "key down" (actually, when both paddles are pressed), the circuit draws between 850 and 1000 microamperes, depending on the setting of the sidetone volume. For this current value the tables of the battery manufacturers show an estimated life of about 450 hours until the battery has been discharged to 5 volts. The battery should therefore be good for well over one year of daily operation. So, once a year let the MINI-MOS keyer have a new set of batteries, whether it needs it or not. The sidetone amplifier, however, at maximum volume draws up to 10 milliamperes of current. With a standard (carbon-zinc) AA cell, this results in a battery life of only about 200 operating hours. If the sidetone is used at high volume settings, use of an alkaline type AA cell is therefore recommended to assure a full year of operation on one set of batteries.

The MINI-MOS keyer can be operated with any single or double (squeeze) paddle key, although the iambic feature can, of course, be utilized only with the latter type. ■

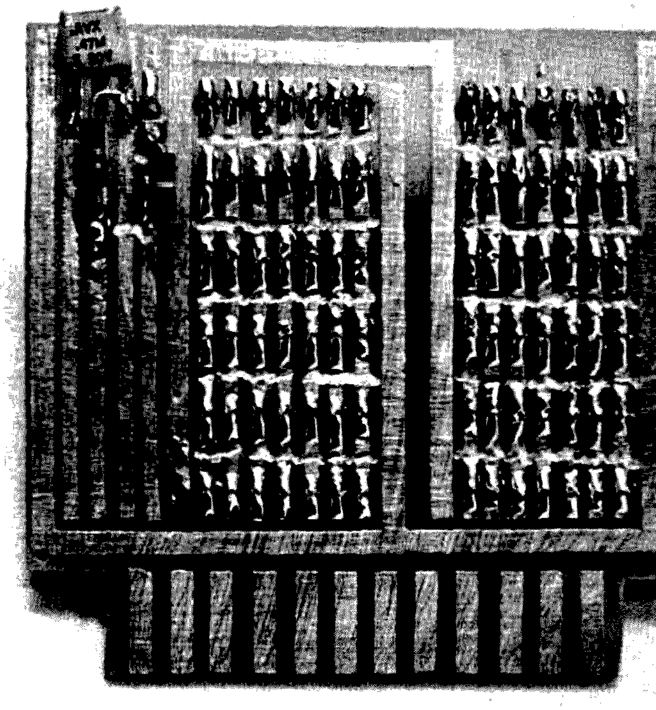
The Skinflint's Delight Breadboard

-- cheap imitation of a commercial IC DIP board

You say you've got that logic system all designed and are ready to give it a try? But you don't have anything to build it on and trying to build it without a circuit board would drive you crazy? And you hate to waste your time designing a circuit board for a circuit that may not even work? For a price, you could buy a bunch of those pre-etched breadboarding cards. Or you could give up the whole thing. Thankfully, there is another alternative.



IC breadboard with no wiring. Note tinned pads and discrete components.

Here is a system I've used with a fair amount of success. It's inexpensive, easy to fabricate, gives a high component density, allows for easy changes, and can perform quite well as a finished product. To be honest, there are disadvantages. Firstly, your eyesight had better be good, since things get pretty crowded (but don't all IC projects?). Also, because of the crowding, a *small* soldering iron (such as an Ungar Princess®) is recommended. Since this is a breadboard, the neatness of the resulting circuit is somewhat less than optimum. If you think the plusses outweigh the negatives, please read on.

What we are going to manufacture is a cheap imitation of a commercial IC breadboard. The board is designed to hold six 14 pin DIP ICs in two columns of three packages. Between each

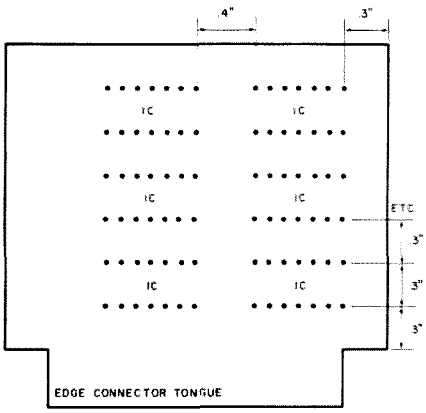


Fig. 1.

column and around the edges of the board are ground and supply voltage buses. A few extra conductor strips may be etched on the board, if desired, for mounting discrete components. Also, one edge of the board can be etched to mate with an edge connector. Getting all of those individual pads etched neatly sounds like quite a job. Luckily, there is a shortcut – called artwork tape. This is a narrow black tape, similar to masking tape, used primarily in drafting. The adhesive used on this tape is fairly impervious to etchant, so the tape can be used as etch resist by direct application to the copperclad board. And since this tape is available in a dozen widths from .015" (that's narrow!) to .25", the required conductor width is easy to obtain.*

How To

Before we start manufacturing the board, the necessary tools and materials should be collected. These are:

Artwork tape, .062" wide (for IC pads)
Artwork tape, .125" wide (for buses and edge connector pads)
Small X-acto knife
Copperclad glass-epoxy board
Etchant (I prefer ferric chloride – it etches fast but it's messy)
Dremel Moto-tool with small burr (optional but very handy)
Small center punch (try not to use an awl – they tend to punch holes clear through the circuit board)
0.1" grid paper
Masking tape
Pencil (with eraser)
Number 65 drill bit (somewhere around that size)
1 pair thin cotton gloves (so you don't get your prints all over the board)

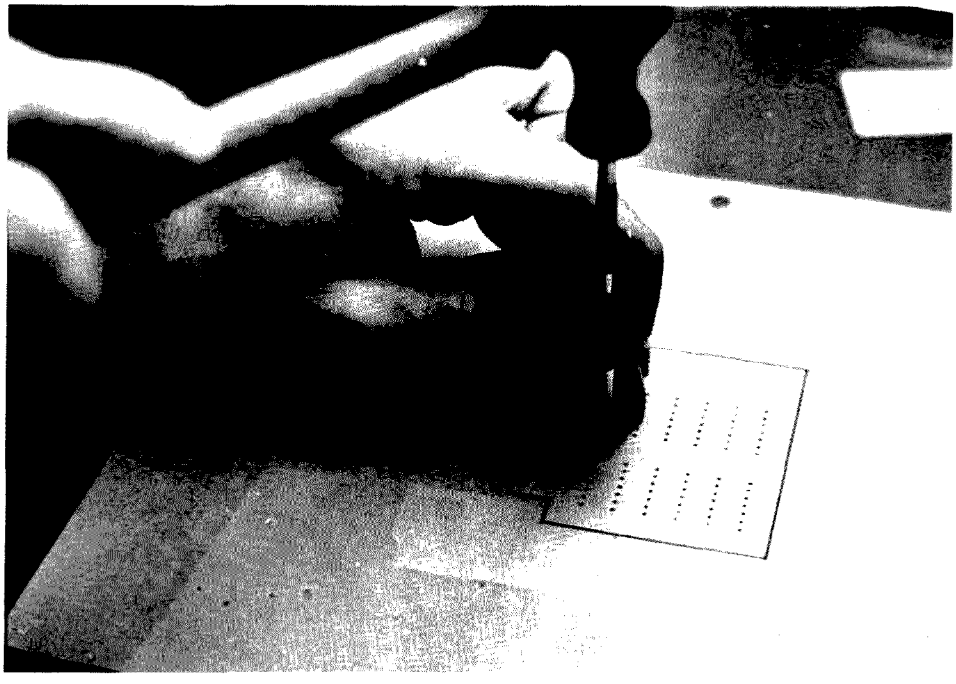
Now we can start. The process begins by laying out the IC pin locations on the .1" grid paper. (See Fig. 1.) Line up the packages parallel to each other with like pins in a line. The pins are separated by .3" and the same spacing between ICs is about right. Between each column of ICs there should be space for two .125" conductors. Allow .4" for this. The edge of the layout should be about .3" from the nearest IC pin location. In the layout shown, extra space has been left on the left side for mounting discrete components. The tongue on the bottom is of proper depth and width to fit an edge connector (measure yours), and starts .3" from the nearest IC pin location.

After the layout is completed, cut a piece of circuit board to the proper size. Tape the paper layout in the correct position over the copper side of the board. With the center punch, punch all IC pin locations hard enough to mark the copper and provide a start for a drill bit (but not hard enough to raise the copper around the punch mark). After punching all pin locations, remove the paper layout.

To prepare the board for application of the resist tape and eventual etching, scrub the copper with steel wool until it's shiny, and then wash it with warm, soapy water. As usual in any PC board article, you are now advised not to touch the copper with any part of your uncovered body (lest lightning strike). Since application of the artwork tape requires much handling of the board, thin gloves are recommended.

Now get out the .062" tape and a knife. We are going to lay a stripe of tape perpendicular to the IC orientation, covering all punch marks in that line. Start the tape about .2" above the first punch mark and end it the same distance below the last. It is easier to apply the tape longer than necessary and then trim it to the desired length. Press the tape firmly to the board with your covered finger or some sort of small roller. Repeat this taping process for all IC pin columns (7 times for one column of 14 pin ICs).

If you have or can borrow a Dremel Moto-tool, you can skip this paragraph. It is necessary to cut a gap in the

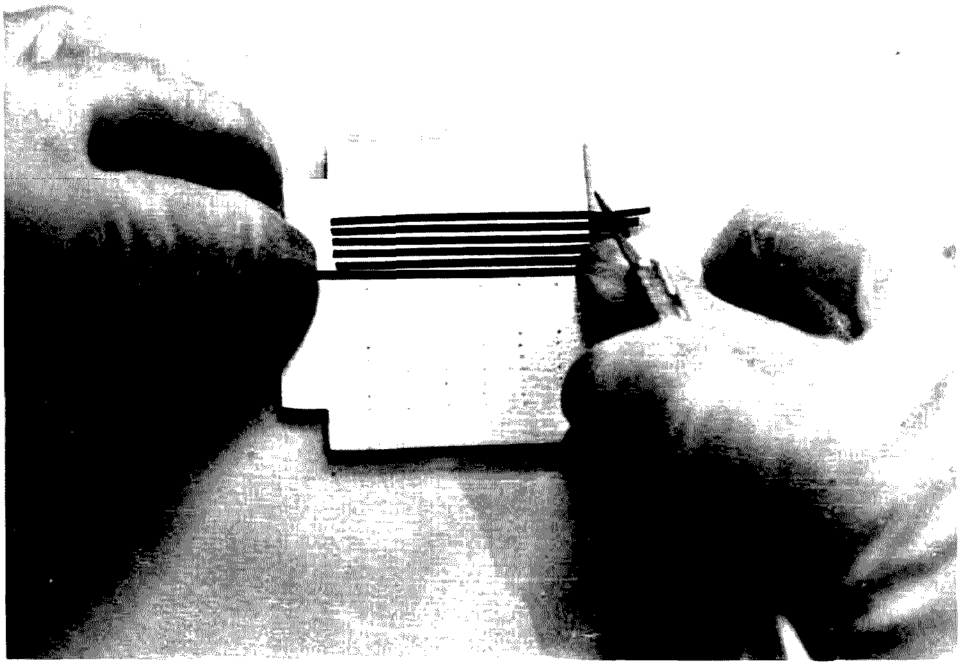


Center punching the .1" grid paper.

*Artwork tape is available from any engineering supply store.

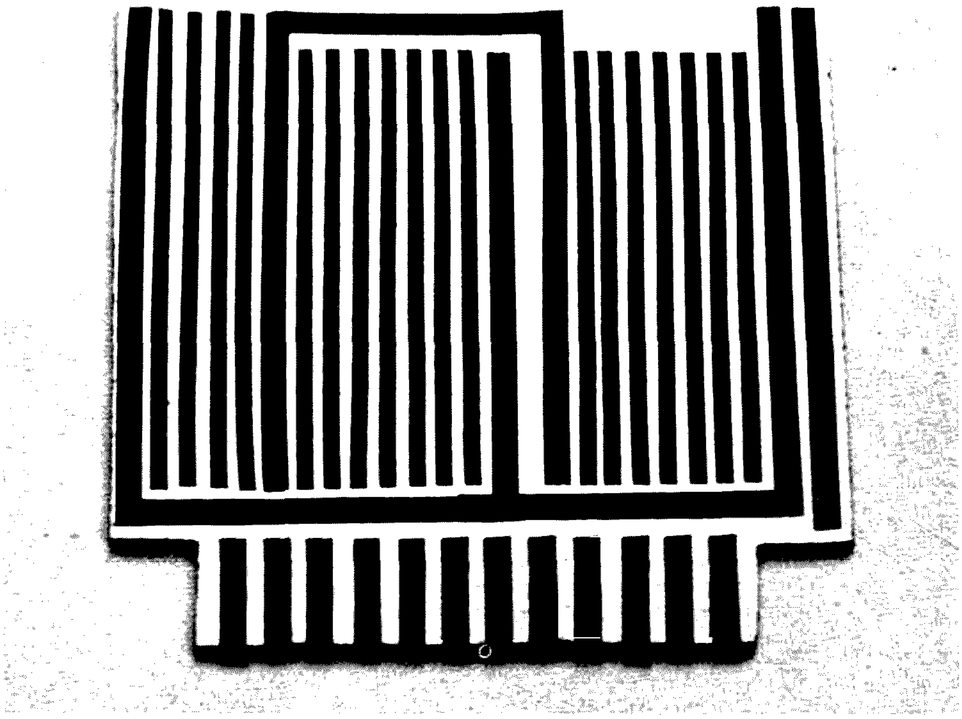
tape between each row of pin locations. Using the paper layout to mark guide points on the board, run your knife blade along a straightedge placed between rows of center punch marks. Remove a small section of the tape from between each pin location. This is necessary to allow the etchant to separate the pads. If a high speed burr is available, it can be used to cut the pads apart after etching (a much quicker process).

Next, the .125" tape is used to lay out power supply conductors. Run a continuous line of tape along the left side and top of the board and another along the bottom and right side of the board. These separate buses then branch off between the IC columns. Make sure that the pieces of tape overlap tightly where a conductor branches, and that there is sufficient gap between buses. Any area left over may be taped to provide independent conductors for mounting discrete components.



Applying tape to the board. Note rows of center punch marks.

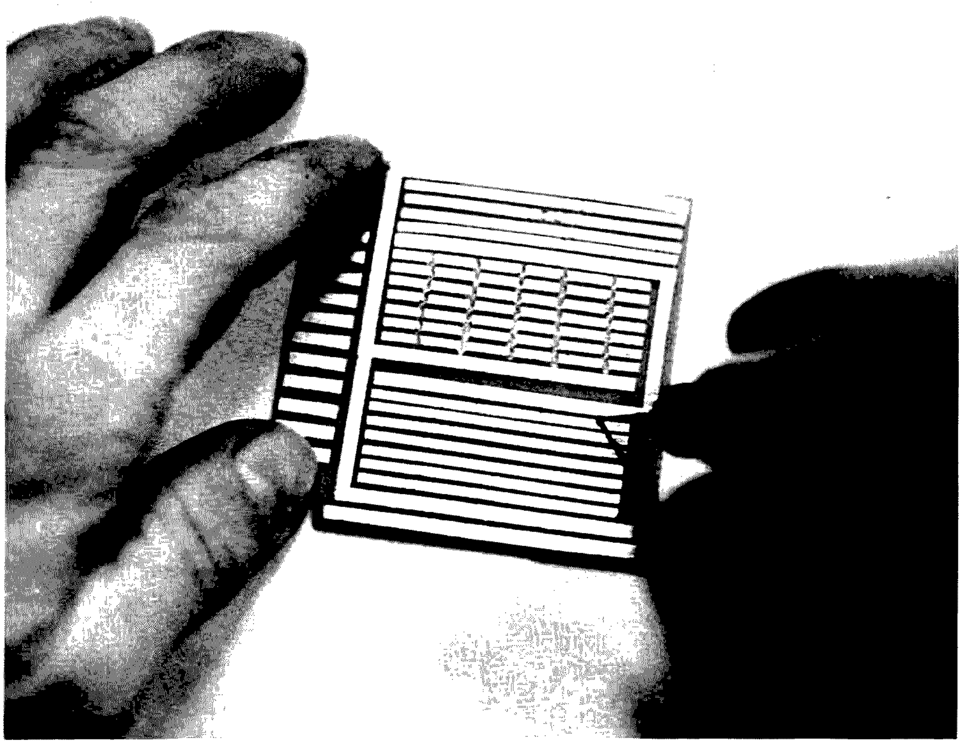
To provide edge connector fingers, tape must be applied to the tongue of the board to exactly match the connector pin spacing. The easiest way to do this is to insert the tongue into the edge connector several times (taking care to remove the connector between insertions). The exact locations of the connector pins will appear as light scratches on the copper. It is only necessary to cover these scratches with tape, and alignment is assured.



Completely taped board.

Now is the time to etch the board. Enough has been said about this process in other articles to avoid the subject entirely. But I can't help myself. An easy way to agitate the board is to drill small holes in diagonally opposite corners and tie a piece of string to each corner. The board can then be dropped into the etchant, copper down, and moved back and forth and up and down during the etching process. This technique will greatly speed up the process, and enables you to handle the board without getting that damned etchant all over your hands.

After etching, the pads are cut apart with a high speed burr (Dremel). Don't cut too deeply or accidentally cut a



Using the burr to cut the pads apart.

supply bus. The use of the burr takes a little practice, but once you get used to it it's a pretty quick process.

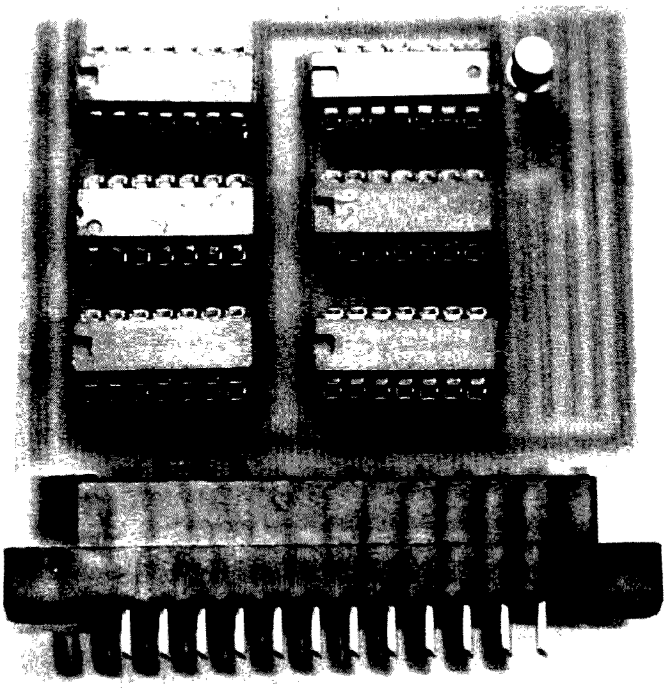
Now comes the most tedious part of the process. Drill all IC pin locations with a No. 65 drill. Insert Molex pins or ICs and solder, tinning the entire pad. Now we've completed what we set out to do.

Wiring

Now that you have a board to mount your ICs on, the only other necessity is a means of connecting them together. For short connections (e.g., Vcc and ground), I use No. 22 tinned solid wire, butt-soldered to the pads. For longer connections, insulation is a necessity. I use No. 24 stranded hookup wire cannibalized from multiline telephone cords. If you need to buy new wire, teflon would be ideal. Since the solder pads are already tinned, it is only necessary to tin the end of a wire and then hold it in place on a pad while applying heat. No additional solder is needed or wanted. Too much solder will only encourage shorts between pads. Wiring can be done neatly, using right angle turns and running the wire only between ICs or running directly point to point. Although the latter method looks pretty bad, it has the advantage of decreased noise pickup from wire to wire, since very few wires run parallel. Besides, it uses less wire.

The extra conductors etched on the board can be used for discrete components. Where a pad for a component is needed, just drill a hole for the component lead and isolate that conductor area by cutting across it with the burr.

The fact that all connectors are hand-wired when using this technique makes changes easy to make. The production cost of this board is much less than that of commercial ones. You can get more components (especially ICs) on this board than on a board with printed wiring, since little room is needed for conductors. And if you can stand the sight of the mess of wiring, the board will make a pretty good finished product. ■



With wiring hidden, board looks almost professional.

More PLL Magic

--like low frequencies for RTTY

This article described a phase locked loop circuit that can be built with a single IC chip. Integrated PLLs are available, but building the loop out of discrete components and IC amplifiers allows for experimentation not possible with the integrated version. In addition, a general discussion of the LM3900 linear amplifier is presented.

This IC contains four identical amplifiers in a 14 pin DIP package. It satisfied the need for an economical op amp device which can operate on a single supply voltage. Those who have struggled with multiple batteries, power supply splitters, etc., will immediately appreciate the advantage of the single power supply feature. And best of all this can be anything from 4 to 36 volts.

A skeleton diagram of the internal amplifier circuit is shown in Fig. 1. Note how this resembles a normal common emitter amplifier rather than the differential stages found in other op amps. With the current mirror circuit at the non-inverting input, single supply operation is possible.

Instead of amplifying voltage differences between the inverting and non-inverting input terminals, this amplifier responds to current differences. The diode between the non-inverting input and ground is actually a transistor with collector and base connected together and the emitter on ground. With IC fabrication techniques, this "diode" transistor and Q1 have almost identical characteristics and track closely over wide temperature ranges. With this situation, it can be shown that the current into the non-inverting input and the collector current of Q1 are equal. Any current I1 flowing into the non-inverting input is "mirrored" about ground and is extracted from the base current for Q2 flowing into the inverting input. If I1 and I2 are equal, the net current into the base

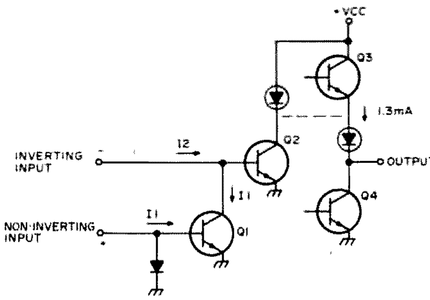

Fig. 1. LM3900 amplifier circuit.

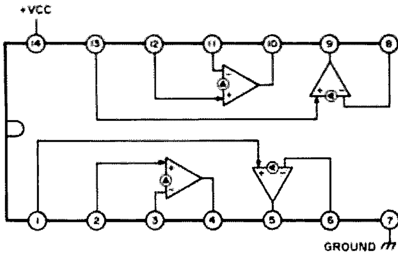

Fig. 2. LM3900 pin connections. Top view of IC.

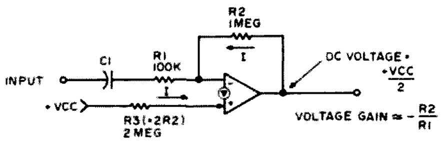

Fig. 3(a). Inverting amplifier.

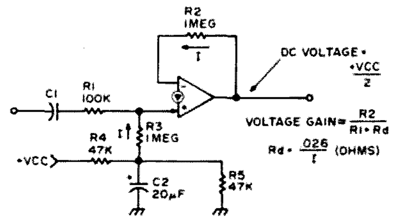

Fig. 3(b). Non-inverting amplifier.

of Q2 is balanced out and current differences between the two terminals are amplified.

As shown, the collector loads for the internal amplifying transistors are current sources. They present high impedance loads for these stages and achieve very high voltage gain. The output stage current is set at about 1.3 mA by its current source. Thus a package of four of these amplifiers draws 5-7 mA idling current. With the internal biasing circuit this current drain is relatively independent of supply voltage.

To provide for amplification with reference to voltages, the input terminals are connected to the signal and bias networks through rather high value resistors, which convert voltage changes into current changes the amplifier can work with. The entire configuration can be thought of as a transistor common emitter amplifier with a very, very high beta and provided with a non-inverting input. As can be seen in the various circuit diagrams, the LM3900 amplifier symbol is drawn with a current source between the input terminals and a current arrow at the non-inverting input. This helps distinguish it from conventional op amp types and also indicates its current differencing type operation. It is sometimes called a Norton amplifier to help make the difference identifiable.

Fig. 2 shows the pin connections for the four amplifiers in a 14 pin IC package. The amplifiers share common biasing circuitry but are otherwise independent for signal paths.

Typical Bias Circuits

An inverting amplifier circuit using the LM3900 is shown in Fig. 3(a). The resistor at the non-inverting input is tied up to the positive supply voltage. Since its value is twice that of the feedback resistor R2 and the currents at the inputs attempt to equalize themselves, the dc potential at the amplifier output biases off at approximately half the dc supply voltage. That is, the same current flows from the output through R2 to the inverting input as from the positive supply voltage into the non-inverting input via its bias resistor. Since R3 is twice the value of R2, the output dc level is half the supply voltage.

Ac signal inputs through the coupling capacitor make the output follow the input with a voltage gain of R2/R1. Note that the output is inverted with respect to the input.

The input bias current required by the IC is extremely small as compared to a regular transistor amplifier. Values as low as 30-50 mA may be used, thus the relatively large value resistors. The normal bias current for the non-inverting input should be limited to something like the 10-100 uA range for optimum operation. Larger values tend to overdrive the current mirror, changing its gain from unity as required to properly mirror the current at the inverting input.

Fig. 3(b) shows a non-inverting amplifier circuit. Note the biasing arrangement here. Again the dc level at the output is set at half the supply voltage. In this case, R2 and R3 are equal, but the bias potential for R3 is at half the supply voltage as determined by the voltage divider R4 and R5. Since the currents (dc) at the input terminals tend to equalize, the output voltage biases off at Vcc/2.

The expression for the voltage gain of the non-inverting amplifier takes into account the impedance of the diode at the non-inverting input. With values in the megohm range for R2 and R3 the effect of Rd is negligible.

For all practical purposes, both amplifiers shown in Fig. 3 have a voltage gain of ten (20 dB). The dc level at the output being halfway between the supply voltage and ground allows for maximum output swing before limiting. The LM3900 has an open loop gain of 70 dB out to 1 kHz and drops off linearly at 20 dB per decade with unity gain occurring at approximately 2.5 MHz. Thus it does not have the extremely high gain of the 741 type of op amp at dc and very low frequencies, but at 1 kHz and above it is about the same. The 3900 is internally compensated for this frequency rolloff characteristic.

With the biasing schemes shown, the LM3900 can be used for any application requiring an op amp. By applying two input voltages through high value resistors, one to the inverting and the other to the non-inverting input, the device functions as a comparator for the inputs. A square wave oscillator is shown in Fig. 4. In this circuit, when the op amp output is at the high level, current flows into the non-inverting input via both 2 meg resistors. When the capacitor charges up to a high enough potential, current flow into the inverting input from this source causes the op amp output to switch over to the low state. With the output low, the effective limiting resistance at the non-inverting input is now 2 megs, cutting its current source in half. As the capacitor discharges and reaches lower voltage level where the current into the inverting input is low enough, the output again switches high and the cycle repeats. By juggling the bias resistor values, different duty cycles can be obtained to produce varying pulse width outputs.

Low Frequency Phase Locked Loop Circuits

The entire loop can be built using one 3900 IC chip, a few resistors and capacitors and one switching transistor.

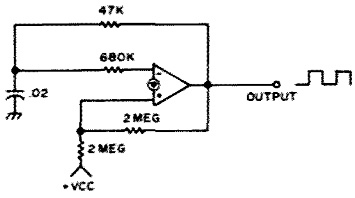

Fig. 4. Square wave oscillator.

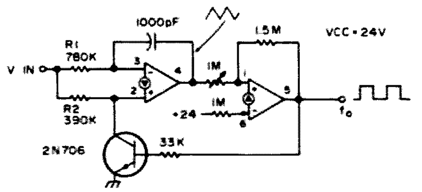

Fig. 5. Voltage controlled oscillator. Note that this circuit has very linear response between 2 and 12 volts.

The main portion of the circuit is involved with the voltage controlled oscillator. A diagram for a vco using two sections of the 3900 is shown in Fig. 5.

The first amplifier in the vco functions as an integrator, and the second is connected as a Schmitt trigger with wide hysteresis to monitor the output level of the first stage. When the Schmitt output is high, the transistor is turned on and diverts current away from the non-inverting input to ground. During this time, the current through R1 into the inverting input causes the integrator output to ramp down toward ground. However, when the lower trip point of the Schmitt circuit is reached, the transistor is turned off, and current into the non-inverting input causes the integrator output to turn around and ramp back up toward the positive supply. Note that the current into the plus input is twice that into the minus input. (R2 is half the value of R1.) With current into both inputs from the source, the effect of current into the plus input overcomes that at the minus since it is twice as large. When the Schmitt circuit flips back over to the other state (high output), the transistor again diverts current from the plus input, and current through R1 takes over making the integrator output again ramp down. And so the process repeats.

The vco circuit alone can be useful and an interesting one to breadboard. With a frequency counter on the output, it becomes a rudimentary form of digital voltmeter since it can be adjusted with the 1 meg pot so that 4 volts input produces 400 Hz at the output, 5 volts gives 500 Hz, etc. The linearity between three and ten volts input is within one half a percent. Not bad for a simple circuit. This curve was run with a supply of 24 volts. Higher values of Vcc are desirable to get good range and linearity. In many applications linearity is only required over a fairly narrow range and this vco will easily do that.

Fig. 6 shows the diagram for the complete phase locked loop. All four amplifiers in the LM3900 are used. U2, U3 and U4 make up the three basic sections: vco, phase detector and low pass filter. U1 is used as an amplifier for the input signal. This stage provides a square wave output swinging over almost the entire supply voltage range. The output symmetry is set by the 10k potentiometer at the input. It limits to square wave output for any input of over a couple hundred millivolts rms. The input impedance is strapped down to about 600 Ohms to make it compatible with typical audio generator and communications receiver outputs.

The vco is the circuit discussed previously. Note that the capacitor in the integrator section is made variable to set the free running frequency. With the high impedance of the LM3900 and the large external resistors, rather small values of capacitance are in order, even for frequencies as low as 1 kHz.

The vco square wave (U4 output) and the limited input signal (U1 output) are applied to U2 which is used as the phase detector portion of the loop. Note that the resistor at the inverting input of this stage is approximately twice the value at the non-inverting input. Thus the signal from the vco tends to take over and control the output of U2. When the input frequency becomes close enough to the oscillator free running frequency, the loop will lock onto the incoming signal and remain in lock for frequency variations within the lock range. The capture and lock ranges are set primarily by the values of RC in the single low pass filter section. Experimentation is in order here as well as in other parts of the circuit.

Once the loop is locked to the incoming signal, the vco frequency and the input frequency are identical except for a slight difference in phase. It is this phase difference which keeps the loop in lock by applying a dc output from the low pass filter to control the vco frequency. Fig. 6 shows the situation for a phase difference of 90 degrees between the outputs of U1 and U4. With these inputs, the output of U2 can only go to the low state during the time the input signal is high and the vco is low. Otherwise the vco signal takes over and drives the output back high due to the 2X difference in input resistors. The average dc level at the output of U2 shown in Fig. 6 is about 3/4 Vcc.

The RC low pass filter smoothes out the U2 output to drive the vco input. If the input frequency changes, the resulting phase change will cause the phase detector output to drive the vco such that it follows the input signal. As the resulting phase differences approach zero degrees and 180 degrees, the vco drops out of lock with the input. During lock the phase detector output will be somewhere between 1/2 Vcc and Vcc. A little study of the phase diagram in Fig. 6 should help clarify this. The important point in understanding loop operation seems to be grasping the fact that it locks onto an incoming signal by virtue of a phase difference between input and vco such that the phase detector dc output is right to make the vco frequency equal to the incoming frequency.

By applying the input signal to the vertical channel of an oscilloscope and U4's output to the horizontal channel, locking can be observed as the input

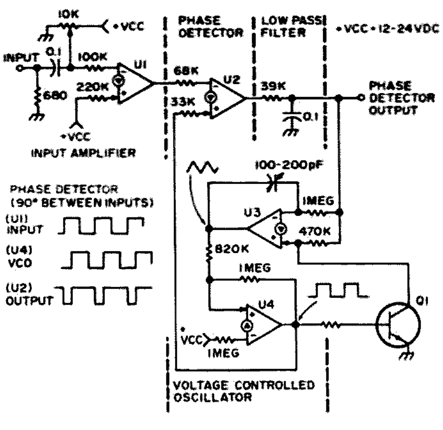

Fig. 6. Phase locked loop using the LM3900.

frequency is swung into the capture range of the loop. Then, as the frequency is varied within the lock range, the Lissajous pattern indicates the phase difference while still maintaining lock. This scope presentation is worth a thousand words while breadboarding the circuit. During lock, the scope display is steady as a rock.

Depending upon the values used in the low pass filter, the lock and capture range can be varied somewhat for specific applications. The values for the circuit in Fig. 6 are suitable for a center frequency of 2200 Hz which is adjustable by the variable capacitor in the vco. Initially, out of lock the loop captures over a range of about 1900 Hz to 2450 Hz. Once in lock, it will maintain lock over a wider range, approximately 1550 Hz to 2900 Hz.

RTTY enthusiasts will note that this frequency range includes the normal tones used in that mode. The dc output variations at the low pass filter are rather small with a 170 Hz shift in frequency, but adequate to drive an IC comparator stage. This makes a single terminal unit with the addition of some sort of keying circuit for the TTY selector magnets. Additional filtering of the low pass filter output is required before driving the comparator to eliminate false triggering of the slicer stage. Other than actually driving a printer with this circuit, no further work was done on a terminal unit for RTTY.

Hopefully, this article will be of interest to those interested in experimenting. The LM3900 itself is so useful in all sorts of applications that after playing with the phase locked loop circuit, the IC can be put to good use in any number of ways. Most of the ads feature this chip for about a half dollar, so getting a few to try is certainly worth the small investment. ■

Table 1. (a) Coding method. Code is typed or printed on masking tape and applied to bottom of ICs. This saves much referencing to the layout diagram and helps avoid wiring to the wrong IC. (b) Suggested list of codes.

The logic probes which are described in amateur radio magazines today are what I call static logic probes. That is, they require that the logic levels they are checking not change at all during the measurement period, or at least not so fast that the eye cannot follow. This is fine for simple low speed circuitry, but won't work well for complex or high speed circuits.

I would describe the S.I.L.T. unit, however, as a dynamic logic probe, as it allows one to make logic level measurements on the most complex and high speed digital logic circuitry one would expect to find in any ham shack. It will do this even while the circuitry is in normal operation. Time periods no longer than 20 or 30 nanoseconds may be "frozen" out of any longer period of time and examined

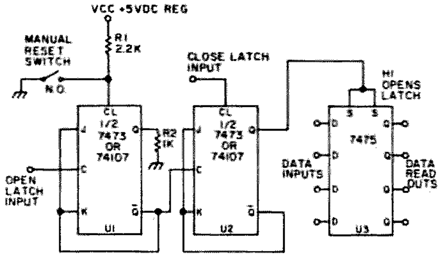

Fig. 1. The basic S.I.L.T. circuit. R1 makes certain that the U1 "CL" input is positive enough to enable U1. R2 is used to satisfy TTL rules and may be replaced by a TTL input or LED readout load.

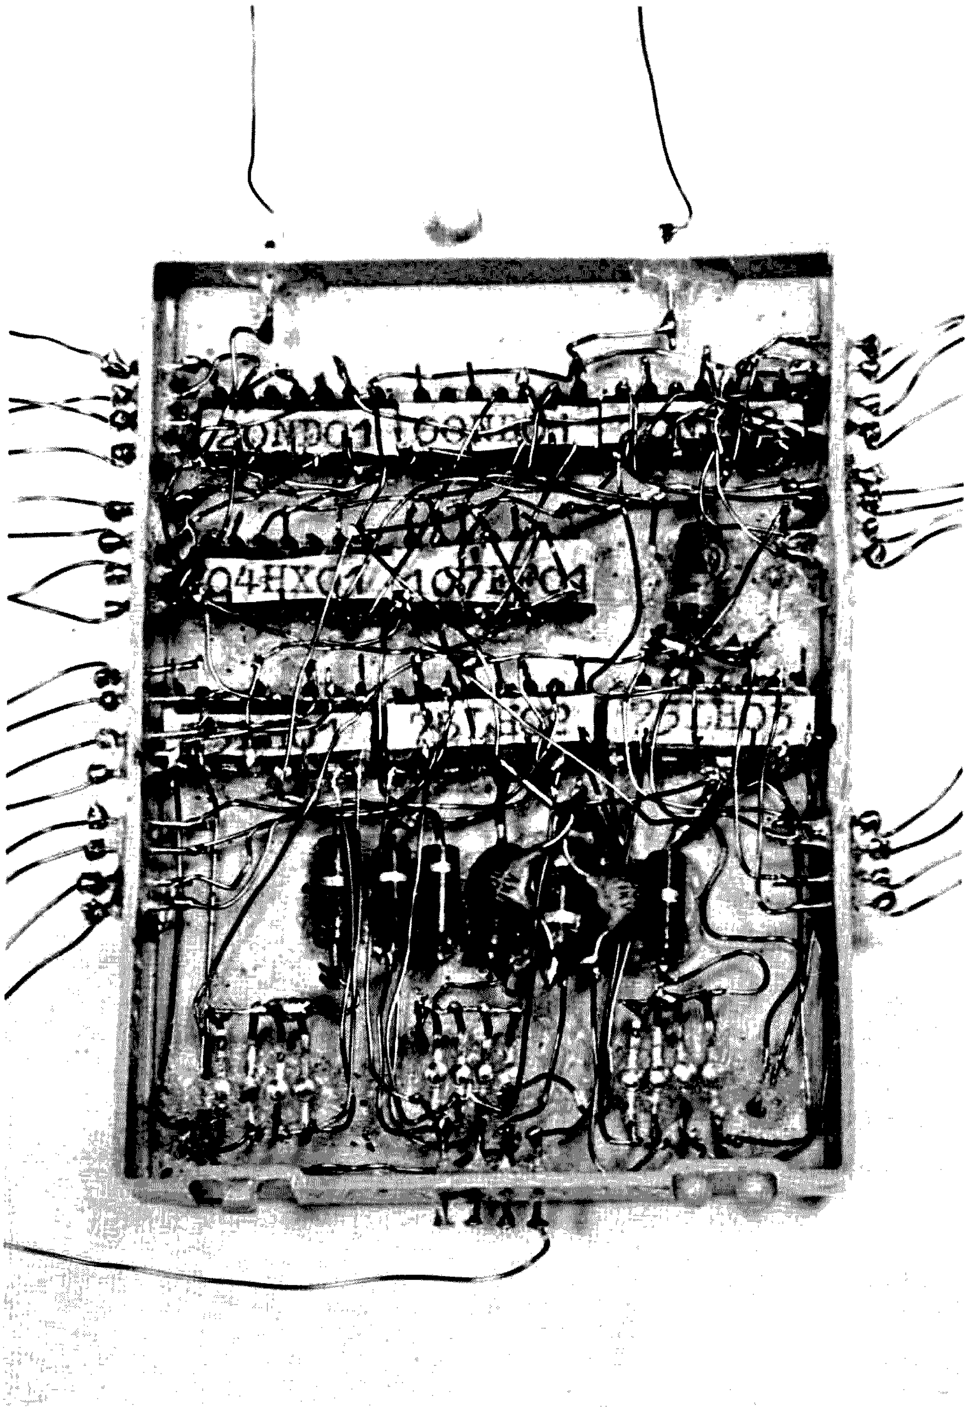
at your leisure for proper pulse coincidence, absence of proper pulse at a specified time, presence of a wrong pulse, etc. This enables the home brewer to determine if his digital logic project is working properly, or to trace any troubles that may crop up in a particular digital logic project.

In this article I will attempt only to describe the heart of the S.I.L.T. unit. The variations that any particular user may want to include with this unit are unlimited, and determined by the type of use to which he intends to put it. You might compare it to a basic meter movement or a cathode ray tube, and the thousands of different uses they may be put to.

In the cases of very complex and/or high speed digital circuits, the S.I.L.T. can take the place of the much more expensive triggered sweep scopes in most amateur applications. The S.I.L.T. cannot, however, display waveforms. It can only tell you if a particular logic state (high or low) is present at any given instant of time – a very useful bit of knowledge, if you think about it.

Fig. 1 shows the basic S.I.L.T. unit. It uses two very common ICs. One is the 7475 quad bistable latch, and the other is the 7473 or the 74107 dual JK flip flop. The only difference between the 7473 JK flip flop and the 74107 JK flip flop is the pin basing diagram. In the 7473, Vcc is pin 4 and ground is pin 11. In the 74107, Vcc is pin 14 and ground is pin 7. Since the other pin connections are also different, I would suggest that when ordering these from your supplier you ask for a data sheet for the units you are getting. As far as electrical and logical operation go, the 7473 and 74107 are identical. For some unknown reason the difference between their prices



varies from one supplier to the next.

Circuit Theory

Before I discuss the operation of this circuit, let me review the operation of the two ICs. The outputs of the JK flip flops will toggle (or shift) logic states at each negative going (high to low) transition of the logic level (at the "C" or "clock" input) *only* if two other logic situations are satisfied. First, the "CL" or "Clear" input logic level must be high. Second, the "J" and "K" inputs must also be at a high logic level.

If the "CL" input is a logic level low, the flip flop will clear and the outputs will be forced to a reset state. That is, the Q output will be forced to a low logic state and the $\bar{Q}$ output will be forced to a high logic state. Logic level transitions at the "C" input will have no effect on the outputs while "CL" is low.

If the "CL" input is high and both the "J" and the

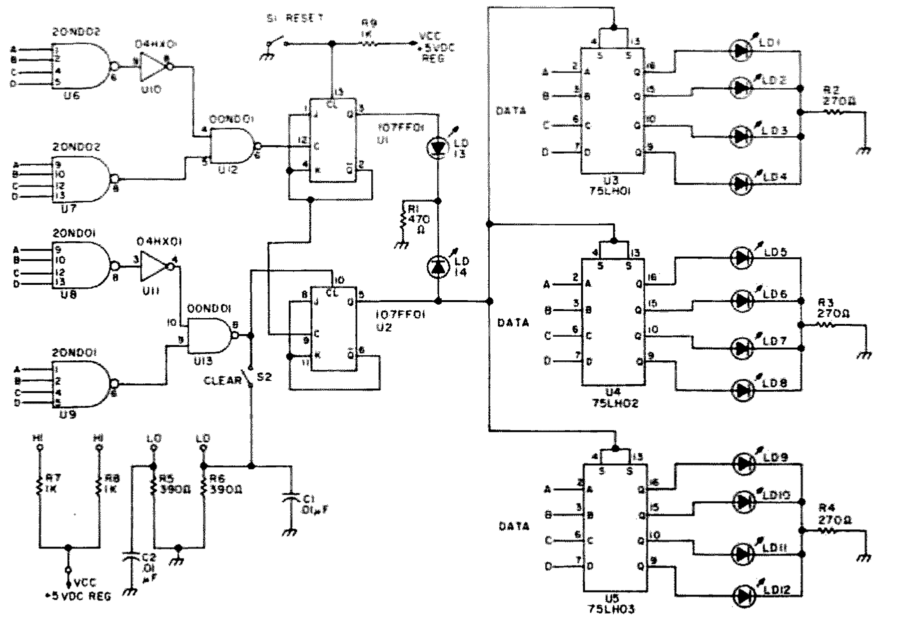


Fig. 2. The D.S.I.L.T. circuit. C1 and C2 are used to provide a direct ground for logic pulses. VCC and GND connections to ICs are not shown, but should be bypassed with at least .001 uF caps. Resistors are ½ or ¼ Watt.

"K" inputs are low, logic transitions at the "C" input will also have no effect on the output. However, unlike a "CL" logic low condition, the outputs will not be forced to a certain logic state, but will hold whichever logic state they had before the "J" and "K" inputs went low.

The "S" or "Strobe" inputs of the 7475 quad bistable latch work in a manner reminiscent of the "J" and "K" inputs of the JK flip flop. Some call this input "C", or "Clock." When the "S" inputs are at a high logic level, the "Q" outputs will reflect exactly the logic levels of their respective "D" inputs. When the "S" inputs go to a low logic level, the data present at the Q outputs is frozen and, even though the "D" inputs' logic levels may change, the data at the "Q" outputs will remain until the "S" inputs go to a high logic level again. It is worth noting that this IC also has the complementary $\bar{Q}$ outputs.

With all of this in mind, I will now go into the operation of the basic S.I.L.T. unit. If the "CL" input of U1 in Fig. 1 is grounded or at logic level low, the outputs will be a low at Q and a high at $\bar{Q}$. If the "CL" input is then ungrounded, it will be pulled up to a high level through resistor R1. Now, since $\bar{Q}$ is still high and it is connected to the "J" and "K" inputs, the flip flop is enabled. A low to high transition on the "C" input will have no effect, but a high to low transition on "C" will toggle the flip flop. The Q output will become high and the $\bar{Q}$ output will become low. Since the "J" and "K" inputs are tied to the $\bar{Q}$ output, they will also be low, and, as I said earlier, this disables the flip flop but does not reset the outputs. Any further activity at the "C" input is ignored by the flip flop. U1 is effectively latched up until a low is applied to the "CL" input.

The U1 $\bar{Q}$ output is also tied to the "C" input of U2. For the moment, let's assume that a high logic level is present at U2's "CL" input, and that U2 has been reset. That is, U2's outputs are Q = low and $\bar{Q}$ = high. Now U1 is tripped as described in the last paragraph and its $\bar{Q}$ logic level drops from high to low. Since this output is also tied to U2's "C" input, the high to low transition trips (or toggles) U2. Also, since U2's $\bar{Q}$ is tied to its "J" and "K" inputs, U2 also latches up just as U1 did. Again, U2 won't reset until its "CL" input goes low.

Since the switch used to ground U1's "CL" input is a manual normally open pushbutton, U1 won't be reset until you want it to be. U2's "CL" input is a test lead, just as U1's "C" input is. Now if I connect U2's "CL" input to a timer, I can cause U2 to reset at any time I choose after U1's "C" input has been tripped. More on this timer later.

Once U2 has been tripped and its $\bar{Q}$ output has gone low, its Q output will go high. Since this is tied to the "S" inputs of the 7475 quad latch, the Q outputs of this latch will follow any data present on the "D" inputs. At that instant of time I selected after U1's "C" input was tripped, a logic level low pulse hits U2's "CL" input and U2 is reset, U2's Q output goes low, and U3's Q outputs freeze on whatever data was present at that instant.

In my own S.I.L.T. units I use LEDs for reading out the data frozen at the outputs. Other readouts might be a VOM, VTVM, BCD to decimal decoder with numeral readout, etc. This will depend on your application. Once you have recorded the data from the outputs, you can hit the reset button and another reading can be taken, or you may want to move your "D" inputs and/or U1 "C" and/or U2 "CL" inputs to other points in the circuit.

Those who have built digital frequency counters will recognize this circuit, since it is the same as the hold latches in a counter. One difference is my method of using flip flops, and the idea of using this circuit as a test instrument.

Yes, the S.I.L.T. unit is very simple, but its uses are almost limitless. Fig. 2 is one example of how I first used the S.I.L.T. principle. This unit is a "Dependent" or D.S.I.L.T. I call it "dependent" because the basic S.I.L.T. unit depends on timing pulses from within the digital unit under test to reset the U2 flip flop.

The operation of U1, U2, and U3 is the same as in Fig. 1. U4 and U5 are also 7475s and are added to the Q output of U2 so that three times as much data can be displayed for each test. LEDs LD-1 through LD-14 are common red mini-LEDs. LD-1 through LD-12 are readouts for the quad latches, and LD-13 and LD-14 are used to keep track of the switching conditions of U1 and U2.

If U1 is reset and Q is low, LD-13 will be off. When U1 is tripped, Q goes high and LD-13 lights to let you know U1 has been tripped. When U2 is tripped, Q goes high

and LD-14 lights. When U2 is reset, Q goes low and LD-14 goes out. R1-R4 are current limiting resistors for the LEDs. Switch S1 is the reset switch. Switch S2 is used to reset U2 in case a low pulse does not arrive at U2's "CL" input.

U6 through U9 are 7420 four input NAND gates. The inputs to these gates may be connected in various ways to the circuit under test so that a selected number of *coincident* pulses will trigger the appropriate response from U1 or U2. Unused inputs may be tied to the appropriate resistor-driven high or low terminals.

U10 and U11 are 7404 hex inverters which invert the outputs of U6 and U8. Their outputs, along with the outputs of U7 and U9, are fed to the inputs of ICs U12 or U13, which are 7400 dual input NAND gates.

My purpose in building the D.S.I.L.T. was to aid in troubleshooting a digital VFO that I have in design. You may not need as many as three latches, or you may require more than three. Also, the inputs may vary to suit your needs. Many methods of construction may be used. I offer my method only to give you some ideas.

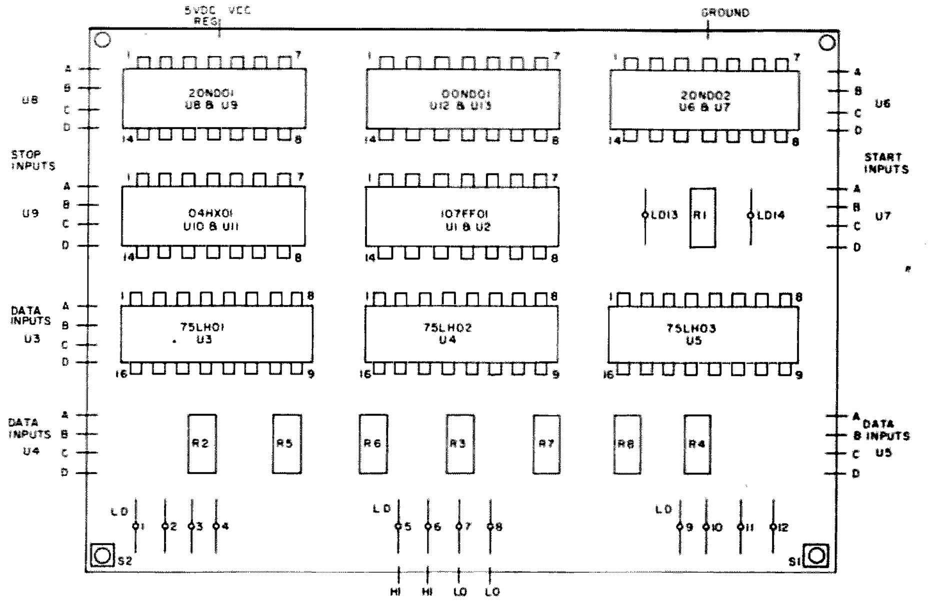

Fig. 3. D.S.I.L.T. layout is very handy for wiring and later troubleshooting. All parts except wiring and capacitors are shown. Caps should be disc types and lie flat across IC pins.

Construction

The first step in the construction process is to choose a wiring method. Printed circuit board is by far the best choice. I didn't choose it because I hadn't had much success with those tenth of an inch IC pin spacings, and also because usually, as soon as I finish etching a PC board, I decide to make a circuit change. Uses for the D.S.I.L.T. are so variable and changing that it may never be put on PC board at this station.

Another choice is perfboard, with molex IC socket pins. I've used this method, but it seems that when more than two ICs are used, a short almost always develops somewhere.

IC sockets are an excellent choice if you don't mind having more invested in sockets than in ICs.

The method I finally chose was a variation of the methods described in a *Ham Radio* article.[1] First, I decided on a layout (see Fig. 3). Then I chose a plastic box of proper size. Next, silicone rubber sealer was applied to the top of an IC and the IC was placed upside down in the bottom of the box so that its legs were pointing upward. Be cautious that you position pin 1 of each IC in the same direction each time, or you'll have trouble identifying the pins. All other parts, LEDs, resistors, and ICs were mounted using this method. If a part needs to be replaced, it is easy to pry it up and "glue" in another.

If you tip a couple of ICs upside down on a tabletop, you will soon discover that if you don't already know the IC number, you've got a problem. Not so. Type the number on a small strip of masking tape. Cut and trim the tape to size and apply it to the bottom of the IC. Better yet, use the coding system shown in Table 1.

The wire I used is #26 Beldsol enamel. It has an insulation that melts off when a high temperature soldering iron is applied to it. Don't worry if you should accidentally touch the wire with the soldering iron. The insulation doesn't come off that easily. Neatness in wiring, in this case, is an invitation to disaster. Direct point-to-point wiring is preferred. *Do not* bundle your wires, as these bundles are fair to excellent transformers for digital pulses. Use extra heavy wiring or copper strapping for the B+ and ground wiring, not so much because of high current requirements, but to cut down the impedance to high frequency square waves.

Using this system with seven or eight ICs, I soon found that wiring errors are next to impossible to avoid. So I developed an idea similar to that used in kit construction. First, I developed the code shown in Table 1. Then, using the pin numbers shown in Fig. 2, I made up the charts shown in Table 2. Following this table I made no wiring errors and the unit worked fine the first time.

I used common pins cut off to about three eighths of an inch lengths to run the wiring through the side of the plastic box. Common pins that are attracted to a magnet seem to take solder best. Again, silicone rubber sealer holds these firmly in place. You have several choices for the other end of your test leads. A large or small alligator clip will allow you to make simultaneous contact with no fewer than two IC pins. This is not exactly what I had in mind. One good choice is the GRABBER Model #3925 mini test clip.[2] This, in my opinion, is the best choice, but for units with as many data and trigger input leads as my D.S.I.L.T., these clips could make up a large percentage of the cost.

The choice I made was to use about two feet of #26 Beldsol wire for each lead and to solder the test lead directly into the circuit under test. This sounds like a nightmare, but it really is very easy — especially on the solder side

*Table 2. D.S.I.L.T. wiring tables from all ICs to their connections. This takes care of all major wiring except for some resistor and switch hookups. The numbers preceded by an * indicate the "fanout" required from an output with more than one connection. Thus, pin 2 of the 107FF01 goes to 3 inputs. Pin 5 of the 107FF01 goes to 7 inputs, which is close to maximum (about 10 TTL loads in most cases). NC means no connection. BLANK means that the IC has no internal connection on that pin.*

of a PC board. A Wald portable soldering iron is a great help, but is not necessary.

The power for the D.S.I.L.T. is robbed from the unit under test. Bypassing is the word to worship here. I bypass every IC with a .001 capacitor.

Switches S1 and S2 are unique. Manufactured switches are (a) expensive, (b) massive, and (c) unnecessary. I built my own SPST switches. First, two pieces of tin or copper are cut to one quarter inch squares. Then, using a center punch, a dimple is made in the center of each piece. A one sixteenth inch hole is drilled through the bottom of the plastic case in one corner. The two wires, one from ground and the other from U1's "CL" pin, are passed through this hole. Either wire is soldered to the dimpled side of one of each of the two squares of metal. Next, one wire is pulled back through the hole until the metal lies flat against the hole (with the bump in the metal facing away from the bottom surface). The metal is held in place by, you guessed it, silicone rubber sealer. Be careful not to get any sealer on the exposed surface of the metal.

Now, before the sealer hardens, the other wire is pulled back through the hole until the other square of metal can be positioned about one sixteenth of an inch above the other and be held there by just the stiffness of the wire supporting it. The bumps on the two squares should be facing each other and almost touching. Apply silicone rubber sealer around the metal pieces, being very careful not to force sealer between the two pieces. The finished blob of sealer should look similar to the little sample the sealer company puts on its cartons to demonstrate its qualities.

This entire procedure should be repeated on another corner of the box, using a wire from U2's "CL" pin and a wire from a resistor-driven logic low terminal. Also, blobs of sealer should be put on the remaining two corners of the case. Once this sealer sets up, these serve as excellent nonskid feet for the D.S.I.L.T. When a corner of the box with the switch in it is depressed, the two pieces of metal are forced together. Releasing the case allows the elastic qualities of the sealer to pull the metal pieces apart.

This simple switch saves much space and money. It also leaves several of my ham friends scratching their heads and wondering where the switch is. Most of these ideas come from trying to do something with as little as possible. They may seem weird, but the fact that they work is all that matters.

I would say that if you understand the logic of the D.S.I.L.T., you can probably use it properly on any logic circuit you *understand.* You may even be able to use it to figure out some logic schemes that you are not sure of.

If you are just starting to study logic circuits, however, I suggest you use the simpler static logic probes before building an S.I.L.T. type unit. Although the D.S.I.L.T. is a very simple circuit, its use does require complex logic. ■

Global Calculations for the DXer

--using a hand calculator

Have you ever wondered how far away that DX location was? Maybe you've even been curious enough to try measuring the distance from a map – and have found that it can't be done very well. Most maps are either too small to measure on accurately, or have inaccurate distances (this is the case for the common Mercator projection), or both. But if you have a pocket calculator and know your latitude and longitude, you can crank out an accurate distance to any place in the world, within a tolerance of a few miles, in a very short time. You don't need pencil and paper, and your calculator need not be a $700 programmable beauty, either. Mine cost $59, and like many under-a-hundred dollar units, it does the job nicely.

What is essential is that the calculator handle trig functions – sines and cosines – and their inverses. A memory register is also useful, although not essential. This means the calculator needed is one step up from the simple four function types that are the cheapest. However, there are many units that list for $100 or under (and sell for much less) that will fill the bill. Included among these are the APF Mark 20 (which I used to work the examples below), the Rockwell 63R and 61R, the Sears ESR, Unitrex 80SR, Novus Math, Casio FX-10, Heath IC-2000 (a kit), and even the Sinclair Scientific (which I've never seen, but understand is listed for only $50). If current calculator discounting practices are any guide, you ought to be able to get this one in trade for a pair of 807s and an old modulation transformer!

Of course, the calculation can also be done, and very efficiently, with a machine like an HP-35 or HP-45. The primary difference is that these machines use Reverse Polish Notation (RPN) which involves a slightly different keying sequence. The mathematics is, of course, exactly the same as given below.

The basic task is to solve for one side of a spherical triangle, given the other two sides and the angle between them. What may be a bit confusing, if you look this up in a reference on navigation such as Bowditch's *Practical Navigator*, is that the *lengths* of the sides of the triangle are stated in degrees in the formula – degrees as seen from the center of the earth. Here's the standard formula:

$$\cos c = (\cos a)(\cos b) + (\sin a)(\sin b)(\cos C)$$

where the quantities are as shown in Fig. 1. Point A is your QTH, point B is the distant location and point C is the north pole.

Solving this can take a lot of key punching, even with a machine to look up sines and cosines for you. And the answer comes out in degrees on the earth's surface, which requires a further conversion. The final blow is that, although a, b and C are angles in degrees, none of them is directly a latitude or longitude. You'll appreciate why in the past this type of figuring went on mainly on ships where position changes slowly. Aircraft navigation generally ignores lats and lons except if an inertial or VLF navigator is aboard, and those gadgets contain a lot of computer.

For our ham purposes, however, the formula can be

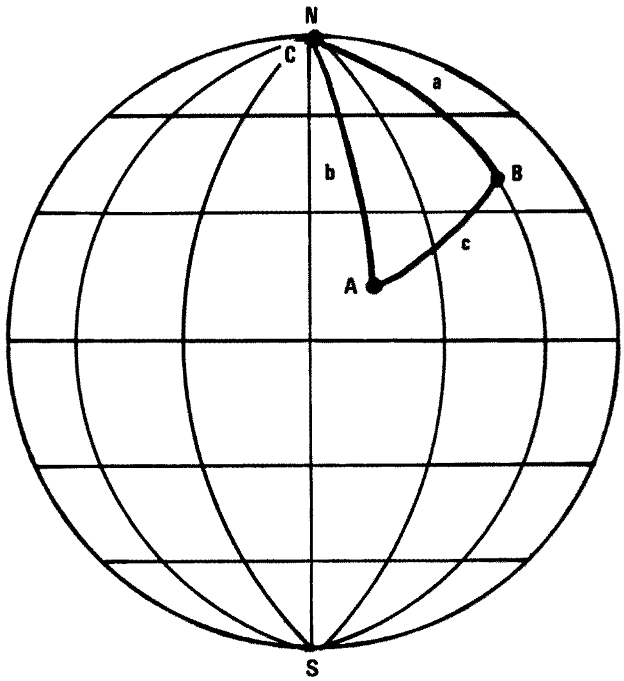

Fig. 1. The spherical triangle.

KEY STROKES	DISPLAY SHOWS	WHICH IS

Table 1.

simplified considerably. The first thing to do is to prefigure two constants from your home latitude: K_1 = cos b and K_2 = sin b. If you're in the northern hemisphere, side b of the triangle is 90° minus your latitude. Huntington, Long Island, New York, where I live, is at 40° 52' north latitude, so for me

$$K_1 = \cos b = \cos (90 - 40^\circ 52') = \sin 40^\circ 52' = .6543$$

and

$$K_2 = \sin b = \sin (90^\circ - 40^\circ 52') = \cos 40^\circ 52' = .7562$$

I plug these two numbers into the formula. They never change, so why recompute them every time? Now we have

$$\cos c = (K_1)(\sin \mathrm{LAT_D}) + (K_2)(\cos \mathrm{LAT_D})(\cos C)$$

Notice that in rewriting the formula I've changed cosines to sines and vice versa so that latitudes can be used directly.

That angle C is the *difference* between your longitude and $\mathrm{LON_D}$, the longitude of your destination. Simple enough; just subtract the larger longitude from the smaller in most cases. What can trip you up is if you're on one side of Greenwich and the distant point is on the other. In that case you add. Three examples should make this clear:

(1) Huntington, N.Y. (73° 19' W) to Honolulu, Hawaii (157° 55' W).

$$C = 157^\circ 55' - 73^\circ 1.9'$$
$$C = 84^\circ 36'$$

Always subtract the larger from the smaller. What you want is a positive number of degrees.

(2) Huntington, N.Y. (73° 19' W) to Moscow, U.S.S.R. (37° 40' *E*)

$$C = 73^\circ 19' + 37^\circ 40'$$
$$C = 110^\circ 59'$$

If this addition comes out to be more than 180 degrees, you've got the long path. Subtract the result from 360 and call *that* C.

(3) Huntington, N.Y. (73° 19' W) to Tokyo, Japan (139° 28' E).

$$C = 73^\circ 19' + 139^\circ 28' = 212^\circ 47' \text{ (too big)}$$
$$C = 360 - 212^\circ 47'$$
$$C = 147^\circ 13'$$

I've rearranged the standard formula for easier use and to come out with an answer in statute miles. The final version is:

$$d = (69.15) \cdot \left\{\cos^{-1} [(K_1)(\sin \mathrm{LAT_D}) + (K_2) \cdot (\cos \mathrm{LAT_D}) \cos (\mathrm{LON_D} \pm \mathrm{LON_H})]\right\}$$

That's still a pretty formidable formula, but it can be worked through without memory stacks or parentheses keys, and without ever needing a pencil and paper (assuming you have a memory in your calculator). The secret is to have this formula, with your two constants already in it, posted in front of you. START INSIDE THE PARENTHESES AND WORK BACKWARDS. Here's how I work an actual example with my calculator, which, like many, has an "F" button to shift the keys from numbers to functions – like sin x, $\sin^{-1}$ x, etc. The two end points are my QTH ($\mathrm{LON_H}$ = 73°) and Anchorage, Alaska ($\mathrm{LAT_D}$ = 61° N, $\mathrm{LON_D}$ = 150° W). I've rounded off Anchorage's coordinates to even degrees. Do this. It saves keypunching, and the maximum error you'll ever get is 35 miles. Big deal.

The calculation we're going to do is:

$$d = (69.15) \cdot \left\{\cos^{-1} [(.6543)(\sin 61) + (.7562) \cdot (\cos 61) \cos (150-73)]\right\}$$

(Clear the calculator completely, and follow the steps shown in Table 1.)

So the distance from Huntington, N.Y. to Anchorage, Alaska is about 3390 miles. Using the minutes and seconds of coordinates as close as I can find them gives 3329 miles. I don't find the difference very significant.

Here's the formula for Huntington, N.Y. to Paris, France, which is on the other side of the Greenwich meridian at $\mathrm{LAT_D}$ = 48.52°N, $\mathrm{LON_D}$ = 2.2°*E*:

$$d = (69.15) \cdot \left\{\cos^{-1} [(.6543)(\sin 48.52) + (.7562) \cdot (\cos 48.52) \cos (73.32 + 2.2)]\right\}$$
$$d = 3596 \text{ miles}$$

The above works for any two points in the northern hemisphere, and can go quite fast.

With your personal version of the formula in front of you, you can run through the calculation (with no goofs) in under two minutes. If, during a phone QSO, someone will give you his latitude and longitude, you can do the whole thing while he's telling you about his super whizbang beam antenna, and get back to him with what we might call the QTD – the distance spanned by the QSO.

What about the southern hemisphere? After all, there are a lot of countries south of the equator. No problem, really: We just need a slight change in the formula. It becomes:

$$\mathrm{QTD} = (69.15) \cdot \left\{\cos^{-1} [(-K_1)(\sin \mathrm{LAT_D}) + (K_2) \cdot (\cos \mathrm{LAT_D}) \cos (\mathrm{LON_H} \pm \mathrm{LON_D})]\right\}$$

The only difference between this formula and the previous one is that minus sign before "K_1 (sin $\mathrm{LAT_D}$)." It can easily be handled if your calculator has a "change sign" key. Just hit it at the end of line 10 in the step-by-step example. Using this for Huntington to Rio de Janeiro, Brazil (LAT = 22.54 *S*, LON = 43.15 W), I get a distance of 4794 miles.

There you have it – a fairly simple method to tell you your distance from any place in the world. If you really get hooked on this game as I have, you might consider owning *The International Atlas* by Rand McNally. It lists 160,000 places in the world alphabetically with their latitudes and longitudes. I'm looking forward to the day when I can work the ultimate in DX. For me that's Augusta, in Western Australia, lat. 34.19 S lon. 115.10 E, distance from my QTH – 11,794 miles. Of course, if I could somehow arrange to work somebody in South Huntington, N.Y. *long path* . . . ■

Instant Counter Calibration

--using your TV set

If this is the first issue of *73* that you've read in the last five years, then perhaps you haven't noticed that we are *over* the threshold of the age of "gnat's eyebrow" frequency measurement! It's rather fortunate that the development of affordable frequency counters paralleled the recent rapid growth of two meter FM, because the serious FMer should have (or have access to) a reasonably accurate frequency counter for netting the crystals in his (her) rig. The luxury of being "talked-in" on the larger systems has passed. For the moment, let's suppose that you have your own frequency counter; how does one go about accurately calibrating (or at least verifying the calibration of) the little gem? Faced with this same problem recently, I began to look around for something *on hand* that would provide a solution (in the time honored "ham tradition"), and came to rest on the TV set, the one-eyed monster. Now, before you leave in disgust, stick with me a little longer and see what a handy little frequency reference a TV set can be when tuned to a network station.

All four TV networks, NBC, CBS, ABC, and PBS, presently use rubidium frequency standards to generate their color burst, horizontal sync pulses, and vertical sync pulses. Some local stations also use rubidium standards locked to the network with which they are affiliated, but unless you are sure, you can't count on it (pun?). These rubidium standards are traceable to NBS (National Bureau of Standards) of WWV fame, inasmuch as the networks are monitored by NBS and offsets are published periodically.

At this point, it should be explained exactly what a rubidium frequency standard is, since it sounds so good. Rubidium 87 is a metallic element whose atomic resonance is 6834.6826 MHz. This natural atomic resonance of rubidium 87 is very stable and not easily upset by external factors (particularly when properly shielded and operating in a temperature-controlled cavity). The rubidium unit influences control on a crystal oscillator, which then adopts the same order of stability as the rubidium reference. The crystal oscillator feeds a frequency synthesizer that contains outputs of 5.0 MHz and 3.579554 MHz (color burst frequency). The long-term (one year) stability of commercially available rubidium standards is $\pm 5 \times 10^{-11}$, and the short-term (one second) stability is $\pm 1 \times 10^{-11}$; these figures improve even more when correlated to NBS offsets.

The TV station uses the 3,579,545.4 Hz color burst signal as a reference for its sync generators, which then derive the familiar horizontal and vertical sync signals used to lock the sweep oscillators in the home TV receiver. The gears are undoubtedly clicking at this point and you're beginning to eye the mahogany knothole with some quick glances.

Here's how you can take advantage of those highly accurate signals that are beaming around us, all of eighteen plus hours a day. The easiest way I've found is to pick up the horizontal sync signal, which is in abundance inside the cabinet of a TV receiver due to its use for the derivation of the high voltage that's needed to run the picture tube. This high voltage spike can be found anywhere around the flyback transformer or the picture tube yoke (which is a safer area to work in). If the set has a wooden or plastic cabinet and your counter is sensitive enough, you may find enough signal to lock on even outside of the cabinet (try the picture tube screen for openers). Note that there is no need to connect either lead from the counter directly to the TV receiver. In fact, unless the TV set is equipped with a power transformer, it would be disastrous to do so (especially if the counter is grounded, which it should be)! Some of the newer portable TV sets have no power line isolation transformers and use bridge rectifier circuits for ac to dc conversion, with the result that even reversing the ac line cord won't place the dc common at ground potential (it's always hot). This situation makes it impossible to hook up externally grounded test equipment to these sets unless an external isolation transformer is used. The preceding was mentioned only to protect the innocent. During a network color broadcast, the horizontal scanning frequency will be 15,734.265 Hz, which I have read on my Heath IB-1103 by simply placing a *well insulated* lead from the counter over the deflection yoke on the neck of the picture tube. You'll notice, if your counter will read below 1 Hz, that the ".265" will vary between counter sampling periods

(because you're not phase locked to the signal, but this is really splitting hairs). It should hit ".265" occasionally. On most counters, if you're within a couple of cycles of 15,734 Hz, you're in good shape. Incidentally, you can use a black and white TV instead of a color set, because its horizontal oscillator is locked to the color standards (H and V sync pulses) as well. Just be sure you are tuned to a network color program. Most network color mobile units now have rubidium standards on board, with the possible exception of the small news "mini-cam" units, so that even in-the-field sporting events will provide accurate sync signals. One more thing: Don't be in a hurry. Give yourself enough time to average the reading over a 10 or 15 minute period. This will give the clocking oscillator in the counter time to stabilize after adjustment, and also will permit you to observe the medium term stability of your counter. Whether or not you actually watch the program on the TV screen is strictly up to you.

There are some inherent errors in the system just described (such as distortion in the microwave relays used for cross-country TV signals, transmission and multi-path distortions within the local "ether," and distortions that take place within the TV receiver itself), but these are *phase* and not *frequency* distortions. So as long as you're not trying to read to three places below one cycle (Hertz), don't fret about 'em (the purists should be happy now).

There you have it: no digging into the circuitry, handy at most times of the day and night, available throughout the country, and very accurate. What more could be asked for? Just one thing – better give the TV set back to the wife and kiddies! ■

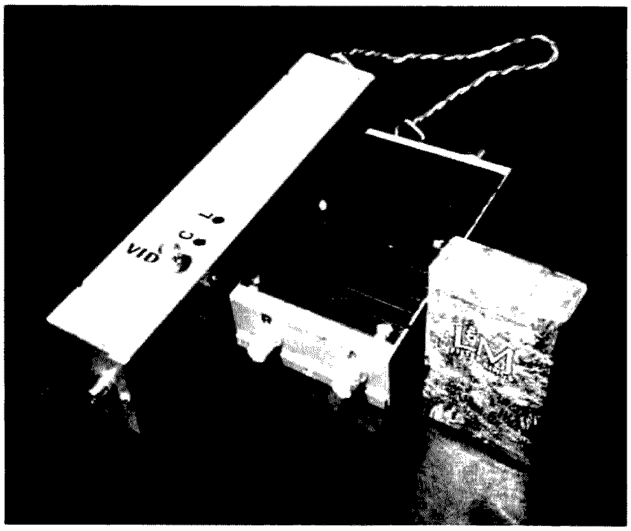

Fig. 1. Low cost 10 Watt ATV transmitter (exciter left, amplifier right).

Here's a compact 10 Watt fast scan amateur television (ATV) transmitter with audio on the video carrier and T/R switching that can be built for about $120 (Fig. 1). The rig incorporates the video exciter described in the June 1976 issue of *73* to drive a quasi-linear 10 Watt 3/4 meter amplifier. No amplifier tune-up is required since it utilizes the Motorola MHW-710 sealed power module. (For theory of operation of this module in the ATV mode, refer to Nov/Dec 1975, page 37 of *73*.)

Operating at 13.8 V dc, the transmitter draws about 2.7 Amps from an external regulated power source. Linearity and frequency response performance is shown in Fig. 2.

As noted above, the construction details for the exciter have already been given; therefore only the amplifier circuit will be described here. Several different mounting arrangements are possible, so you may wish to deviate from the following procedure. Of course, both the amplifier and exciter can be collocated in the same enclosure; however, experimentalists may prefer the two-box modular approach to effect rapid exciter or amplifier interchange with future designs.

Super Simple 450 MHz Rig

--go ATV with a $42.50 module

Bruce J. Brown WB4YTU/WA9GVK
4801 Kenmore Ave #1022
Alexandria VA 22304

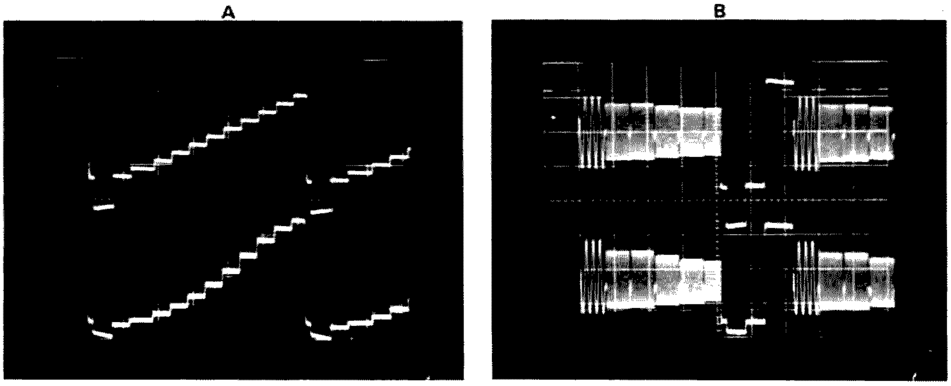

Fig. 2. Performance curves, 10 Watt ATV transmitter. All vertical scales uncalibrated. Power: 13.8 V dc @ 2.7 A. (a) Linearity: top scale — video in; bottom scale — detected rf output; 10 usec/div horizontal; 10 Watts out (average). (b) Frequency response: top scale — video in; bottom scale — detected rf output; 10 usec/div horizontal; burst order (in MHz) — 0.5, 1.5, 2.0, 3.0, 3.58, 4.2.

Amplifier Construction Procedure

Refer to Parts List and Fig. 3.

1. Drill holes in chassis and heat sink per Figs. 4 and 5. Make sure that holes in heat sink line up with holes in chassis.

2. Referring to Fig. 6, mount all components to PC board. (Foil layout for board is shown in Fig. 7.)

3. Using two #4-40 screws, lockwashers and nuts, bolt PC board to two "L" brackets as shown in Figs. 8 and 9.

4. Spread heat sink compound over back of heat sink and Motorola MHW-710 module. Place module on inside of chassis and heat sink on outside. Place PC board mounting brackets on module. Position brackets, module and heat sink so that all holes line up. Bolt all together with two #6-32 screws, lockwashers and nuts.

5. Using four #8 screws, lockwashers and nuts, bolt the corners of the heat sink to the chassis.

6. Solder all seven pins of the module to the PC board (pin numbers shown in Fig. 7).

7. Mount 3 BNC connectors, feedthrough capacitor and ground lugs to chassis. As shown in Fig. 9, also secure a #8 terminal lug to one of the screws holding the heat sink to the chassis. This is the relay ground lug.

8. Run twisted #20 wires from the feedthrough capacitor and ground lug (next to feedthrough) to + and GND on the PC board respectively. Solder a 500 uF electrolytic capacitor across the feedthrough and ground lug.

9. Completely cover the transparent plastic sides and end of the relay with copper foil. Also run a .2" strip of foil across the bottom of the relay (where the contacts are). The relay socket is not used. Solder all copper foil pieces together to insure a good shield.

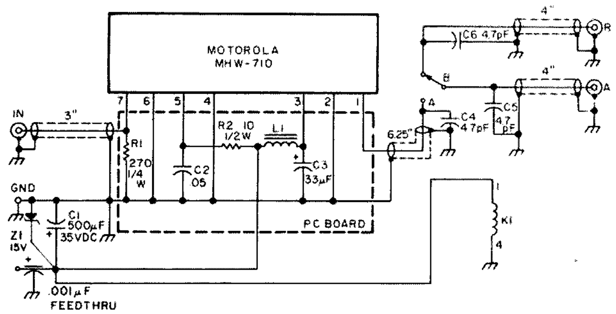

Fig. 3. 10 Watt amplifier schematic. K1 is Archer (Radio Shack) #275-206 relay. L1 is Ferroxcube. VK200-20/4B.

10. Position the relay as shown in Fig. 9. Terminals A and B will be up. Solder the #8 terminal to the copper foil at the end of the relay opposite from the contacts. This will partially secure the relay in place while also grounding the relay's shield.

11. Solder wire from the ground terminal to terminal #4 of the relay. Solder a wire from the feedthrough capacitor (+ V dc) to terminal #1 of the relay.

12. Prepare four RG-188 cables as shown in Fig. 10.

13. Connect the 3" cable from the "IN" BNC to "IN" on the PC board (module pin 7). Solder the cable shield directly to the grounded portion on the BNC connector. The other shield is inserted in the hole provided on the PC board and soldered to the foil. All shield lengths must be as short as possible.

14. Solder the ½" long center conductors and shields of the two 4" long cables to BNCs "A" and "R." Also solder the ½" long center conductor and shield of the 6¼" cable to "OUT" on the PC board (module pin 1). Again keep shield lengths as short as possible.

15. Solder the 1¼" long center conductor of the cable from the PC board to terminal A of the relay.

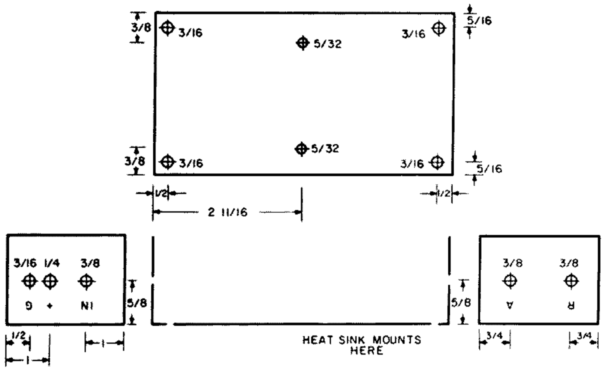

Fig. 4. ATV 10 Watt amplifier chassis drill guide. Notes: All dimensions are in inches. All measurements are from outside edge of chassis. Chassis is LMB #139. Guide is not drawn to scale.

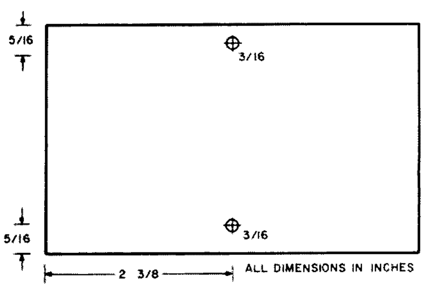

Fig. 5. Heat sink drill guide. Heat sink is International Rectifier HE330-C or Wakefield 623-K.

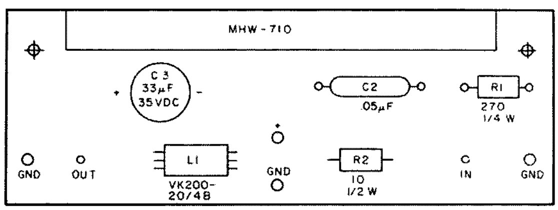

Fig. 6. 10 Watt ATV amplifier PC board, component side.

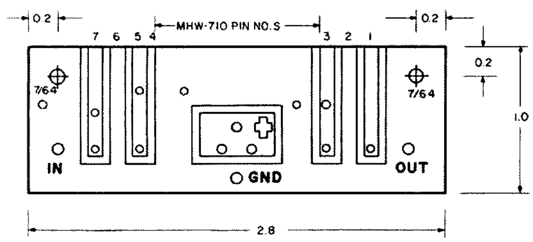

Fig. 7. 10 Watt ATV amplifier PC board, foil side. All dimensions in inches. Board is glass.

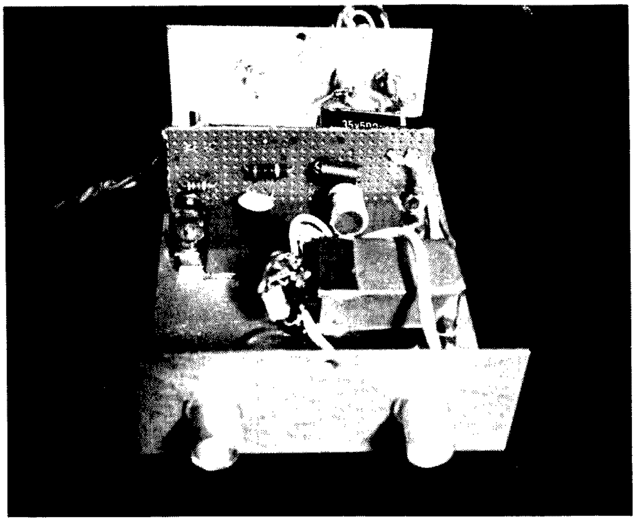

Fig. 8. PC board, prototype shown.

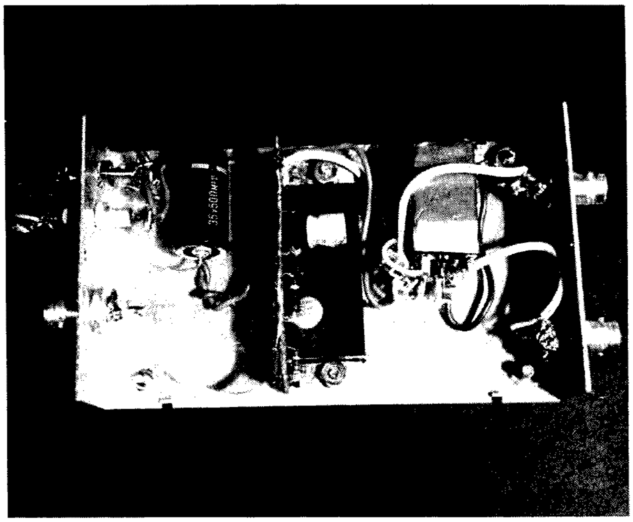

Fig. 9. Internal (bottom) view.

Solder the shield to the relay's copper foil near the terminal thus creating a small loop. Solder a 4.7 pF capacitor between the grounded shield and the terminal (see Fig. 11). Solder the cable from BNC "A" to relay terminal B in like manner. In the same way, solder the cable from BNC "R" to the relay terminal immediately below terminal A. Again all shield lengths should be as short as possible. Also keep loops as close as possible to their respective capacitors.

16. Screw on bottom cover of chassis and label using stick-on lettering (see Fig. 4 and 5 for lettering).

17. The amplifier is now complete (see Fig. 12).

Tune-Up With QRP Rig

Connect a short length of RG-58 coax from the "OUT" connector on the QRP transmitter to the "IN" connector of the amplifier. Also connect a through-line wattmeter and dummy load or antenna to the amplifier's output (BNC "A"). Apply 13.8 V dc from a regulated 4 Amp continuous supply to both the amplifier and exciter.

Basically follow the tune-up procedure given in the QRP rig article. Of course, now you will be aiming for a good picture at about 10 Watts instead of ¾ Watts. The following suggestions may be of help:

a) Remove the core from L6 on the exciter. Set the "L" (level) control fully counterclockwise. These actions will knock down the drive level which should make tune-up easier.

b) Start with "C" (contrast) control fully clockwise.

c) Adjust output modulation and power levels using the 4 variable capacitors in the exciter's output circuitry.

Don't rely too heavily on the picture you see on your local TV monitor since the 10 Watt transmitter will probably overload it. Try to have an on-the-air station, remotely located, assist you. If you use a coupler, detector and oscilloscope to tune up the rig, you may note a 15 to 20 MHz oscillation on the signal. It will generally not be observable on your TV monitor. To attenuate this parasitic signal, adjust L1 through L5 for minimum oscillation amplitude.

A complete ATV station is shown in Fig. 13. Be sure to use hardline and a good antenna for best performance. As explained in the QRP article, a separate receiver is required to derive audio from a signal using the audio-on-the-carrier format.

Important Design Notes

Amplifier power output is highly dependent upon power supply voltage. A 1 volt difference can result in a 3 Watt difference in output

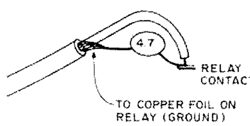

Fig. 11. Relay contact connection.

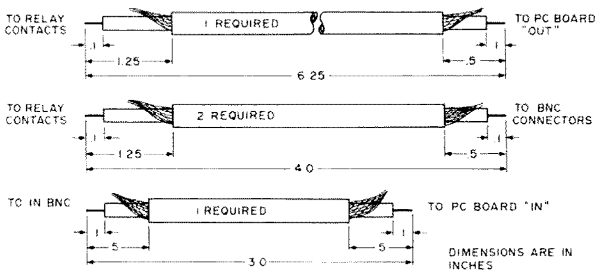

Fig. 10. RG-188 cable preparation.

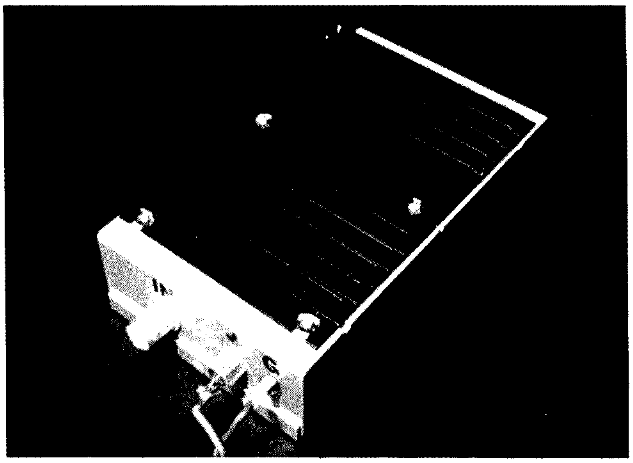

Fig. 12. Amplifier, top view.

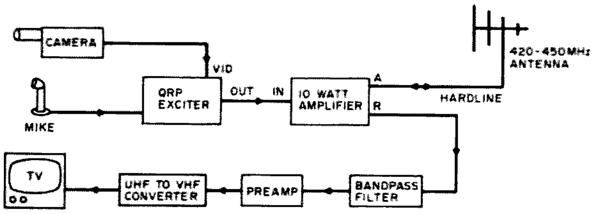

Fig. 13. Typical operational configuration.

power. To achieve a good video signal at 10 Watts average power, 13.8 V dc must be used. Current drain will be slightly less than 3 Amps. If the amplifier is driven hard into a class C mode (no video), it will be possible to initially obtain about 15 Watts. You will note that as the amplifier warms up, the power output will drop. This is natural operation for the Motorola module. Also don't be alarmed if the heat sink and case get very warm. This, too, occurs in normal operation. If you should use the amplifier without video, try not to overdrive it. Use the minimum drive power necessary to achieve full output power (about 300 mW). You will generate fewer spurs while also reducing possible damage to the input of the 710 module. WARNING: When exciting the amplifier, always make sure that BNC "A" is loaded. I smoke-tested the amplifier with about ¾ Watts drive and no load and found that the amplifier self-destructed in 2 minutes (an expensive experiment at $42.50 a module!). The MHW-710 is rugged and can handle short periods of misuse but don't overdo it.

When procuring the 710, you will note that two models are available: the 710-1 for 400-440 MHz and the 710-2 for 440-480 MHz. I have used both types and found that they perform equally well in the 435-450 MHz portion of the ham band.

If you can't get at least 15 Watts from your amplifier at a cold start using 13.8 V dc, you may be experiencing high losses in the relay circuitry. To verify this, connect a cable directly from the wattmeter to "OUT" on the PC board. Normally the relay will exhibit a 1 Watt loss in the 15 Watt range. Relay efficiency is highly dependent upon the length of cable between the relay and PC board "OUT." If you do have a loss problem, experiment using different cable lengths.

The rig is placed in transmit by applying voltage to both the exciter and amplifier power terminals. This arrangement is rather unconventional for normal PTT use, but has been implemented here for simplicity. You may wish to use the spare set of relay contacts and mount additional feedthrough capacitors to achieve a standard switching scheme.

ATV 10 Watt Amplifier Parts List

Part #	Description	Qty	Unit Cost	Total Cost	Source of Supply
1	5½"x3"x1½" Chassis; LMB #139	1		$2.00	Electronic Supply Store
2	UG-1094 BNC Bulkhead Connector	3	S .85	2.55	Electronic Supply Store
3	.001 uF feedthrough cap; Erie #327-005-X5UO-102M	1		1.62	Electronic Supply Store
4	3/8"x3/4" "L" bracket; Calectro #J4-641 (2 brackets in package)	2		.49	Electronic Supply Store
5	Heat sink, 3"x4.75"x0.46" International Rectifier HE330-C or Wakefield 623-K	1		2.72	Electronic Supply Store
6	Heat sink compound; Archer 276-1372	1		.89	Radio Shack
7	½" #8 screws, nuts and lockwashers (to mount heat sink to chassis; also for gnd lug)	5			Hardware Store
8	½" #6 screws, nuts and lockwashers (to mount MHW-710 with "L" brackets to chassis)	2			Hardware Store
9	#8 hole terminal lug; Waldom #KT-198	3			Hardware Store
10	#8 nut (to secure ground lug soldered to relay)	1			Hardware Store
11	¼" #4 screws, nuts and lockwashers (to attach PC board to "L" bracket)	2			Hardware Store
12	RG-188 cable	18"		3.00	Cable & PC Brd both from Stu Mitchell
13	Amplifier PC board; cut, etched and drilled	1		Ppd	WAØDYJ, 14761 Dodson, Woodbridge VA 22193
14	MHW-710-1 or -2 Power Amplifier Module, Motorola. The 710-1 covers 400-440 MHz; the 710-2 covers 440-480 MHz. Either device will give equivalent performance in the 435-450 portion of the band.	1		42.50	Call local Motorola sales office for source
15	#20 stranded wire, insulated	20"			Electronic Supply Store
16	Stick-on lettering kit				Stationery Store
17	DPDT relay, 12 V dc; Archer #275-206	1		3.99	Radio Shack
18	Copper foil, Circuit-stick #9252	1		1.49	Electronic Supply Store
L1	2½ turn ferrite choke; Ferroxcube VK200-20/4B		.51	1.02	Eastern Components 1407 Bethlehem Pk. Flourtown PA 19031 S10 min. order
C1	500 uF, 35 V dc, Axial #272-1018	1		.89	Radio Shack
C2	.05 disc, #272-134	1		.39	Radio Shack
C3	33 uF, 35 V dc, PC Type, Lead aluminum	1		.30	Lafayette; Elec. Supply
C4-6	4.7 pF (or 5 pF), #272-120	3	.29	.87	Radio Shack
R1	270 Ohms, ¼ Watt, 10%	1		.10	Electronic Supply Store
R2	10 Ohms, ½ Watt, 10%	1		.12	Electronic Supply Store
Z1	15 V zener, 1N4744	1		.40	Electronic Supply Store

A 13.8 V dc power supply with a rating of 4 Amps continuous is required.

Acknowledgements

I am grateful to Charles Spitz W4API for providing many of the components used in the development of the rig. Terry Fox WB4JFI provided many valuable suggestions and also supplied the test equipment used to optimize the design. Stu Mitchell WAØDYJ/4 fabricated the PC board. ■

I/O EDITORIAL

PHOOEY ON COMPUTERS

Every now and then I get a letter complaining about the I/O section of *73*. They are in the middle of bundles of compliments, but that doesn't mean that I ignore them, for I know the heavy emphasis on something new like this is bound to get a few backs up. I haven't yet forgotten the ruckus when I decided that FM was a comer and should be pushed . . . and that was seven years ago!

Phooey =1. A letter from an old old-timer says that if he wants to read about I/O stuff he would read a magazine in the field. That's baloney because there *is* no magazine as yet providing fundamental material for newcomers to the computer field. Having started one magazine and preparing a second in the computer hobby field I think I can speak with some authority on that. The new magazine will *not* be on the fundamental level of the articles in I/O, by the way.

Phooey =2. Amateur radio is only a hobby, so I don't have to keep up with new developments if I don't want to. Yes and no. Amateur radio exists because it provides services . . . some during emergencies . . . some by virtue of pioneering and inventive efforts. If you are not doing anything of public benefit then you are a freeloader and are riding the coattails of others who are pulling the freight. The least you can do is shut up and not screw things up for those who are making all this fun possible for you.

IBM's advertising department came up with the concept of different generations of their computers. It was a tremendous put-down for other manufacturers when IBM was always one generation ahead of the others. The concept is a valid one . . . in amateur radio we've had the spark generation, the tube generation, the transistor and the IC . . . and now we're faced with what is for us a fifth generation of design . . . the super-IC. An IC usually has a bunch of transistors built into it . . . sometimes dozens. But the technology has moved ahead now where they are cramming thousands of transistors on ICs . . . LSI, Large Scale Integration, they call it . . . and this is one or two orders of magnitude improvement over those puny little ICs of last year. In three or four years they are looking for super LSIs with millions of components on them, and that might qualify as another generation.

Not only can amateurs keep up with this technological pace, they can pioneer with these new components. The new computer chips weren't designed for use as computers at all . . . they were designed for being built into cars to control their many functions, into cash registers, and other such machinery. It took hardly any time at all for a hobbyist to come along and find out that these chips make perfectly good computers . . . and the race was on. Many are being used for processes such as RTTY and slow scan TV, others are being set up and programmed just like the $1 million computer systems. The LSI is there and what is done with it depends upon us.

MONEY . . . PRESTIGE . . . FAME . . . ETC.

All these things can be yours . . . in modest amounts, of course. All you have to do is trade on your expertise in computers, if any, and help us get articles on the latest microcomputer systems and hardware to our readers. About the only prerequisite is some experience with computers as a hobby . . . preferably with a strong ham slant. It is also helpful, but not absolutely necessary, if you can write.

With more and more hobby computer systems coming out, all of us want to know as much as we can about them. How easy or difficult are they to build or get working? What problems do we run into and how are they solved? What accessories or I/O devices will work with them and how do you hook them up? How helpful was the instruction book? How much did the whole thing cost? How helpful was the manufacturer with problems? What could you do with it once you got it together and working? Have you made any changes or improvements to the equipment? Where have you gotten programs for it? Things like that.

I'd love to publish detailed articles on every microprocessor system being used by hobbyists . . . plus the accessory boards such as the Processor Technology and Godbout boards . . . and, unlike at least one of the other magazines, we do not require a Ph.D. level of writing, nor will we accept it.

If you run into any device or circuit that looks like a good deal for the hobbyist, please give serious thought to writing it up so the rest of us can learn from you. Getting information around in this new field is one of the toughest problems. Let's try to prevent too many of us from inventing the same damned wheel . . . okay?

COMPUTERS ARE HERE

The first of what we hope will be a long string of books for the computer hobbyist is now on the presses and is due out shortly. This book covers the basics of computers . . . the circuits involved . . . such as gates, flip flops, TTL logic . . . counting in binary . . . TVT units . . . Baudot/ASCII conversion systems . . . things like that. It is a good starter book for the ham without a lot of background.

We're anxious to put out a lot more books for newcomers to the computer hobby, so if you think you have the making of a good book in you, you could do worse than write to me giving an outline of the material you want to cover, a sample chapter or two, and info on how you will illustrate it. Books should be well illustrated . . . drawings, photographs . . . and we can help with this to some extent.

If you are into programming perhaps you have been at it enough with your own computer to put together a book on BASIC for the hobbyist, or FORTRAN . . . etc. You should give the user an idea of where to get the assembler for his machine . . . and then how to use the language. I suspect that we will eventually have all sorts of languages available for our hobby systems . . . plus instructions on how to use them. I'd love to have all the major languages available on cassette tapes and sell them via computer stores, but that will depend on super-programmers taking the time to develop them and letting me sell the cassettes for them on a royalty basis.

Let's get a lot of books out to help computer hobbyists learn how to use and develop their systems!

TRENTON COMPUTERFEST

In addition to exhibits by many of the manufacturers in the microprocessor field, there was a very brisk flea market going at Trenton on May 2nd. To give you an idea of some of the fantastic bargains, the brand new Burroughs mag tape unit with its own keyboard and documentation went for $75 . . . eat your hearts out over that one!

As at the Albuquerque computer convention, the main system up and running and doing anything much more than playing games was an amateur radio application . . . this time an Oscar computer which had more information available about Oscar 7 than most of us would ever want to know. Once you put in your latitude and longitude coordinates and got its clock set on time, it could tell you exactly what time you could access the satellite . . . it would aim your antennas and follow Oscar across the sky . . . and even adjust your frequency to take care of the Doppler shift!

The next big computer convention is scheduled for Atlantic City, August 28-29th. It looks like fun.

by John Craig

I/O REPORT

Writing for the I/O section of *73* is a great way to become *rich and famous*. (Probably a lot more of the latter than the former, too!) In all seriousness, it can be profitable . . . we pay quite well for accepted articles. If you're like most computer hobbyists, you're always looking for those extra dollars to buy this or that peripheral. (And, of course, it always looks good on a resumé to have been published professionally.) But . . . and this is certainly important . . . you needn't be a professional writer to sit down at the old typewriter and pound out an article for our I/O section. Here are some guidelines to help you along . . .

WHAT TO WRITE ABOUT

Naturally, since we are a ham radio magazine, we're constantly on the lookout for interesting articles dealing with amateur radio applications. But something we should all keep in mind is that the thousands of hams interested in and using computers are going to be using their home systems for things other than ham radio. Therefore, we're going to be looking for articles covering the broad spectrum of hobby computer construction, programming, and applications.

One of the most interesting things for most of us is to read about some piece of equipment that someone has designed and built. While most of us will not be actually building the unit, we'll follow the construction in our minds and enjoy reading about it. With well over 100,000 readers, just about anything described will be built by at least a hundred or so people. It pays to be extremely careful in checking your article for just one mistake . . . or the mail comes pouring in.

If you happen to be doing experimental work in an advanced field that would be of interest to us, you might write about that. We make a particular effort to keep *73* ahead of the other magazines in publishing new discoveries and advancements. Remember that you're writing for the average ham and/or computer hobbyist . . . not engineers.

THE PLAN OF ATTACK

Generating an outline of your proposed article is perhaps one of the most important steps you can take (as well as, of course, sticking to it and not getting sidetracked). Remember the old rule: "Tell them what you're going to tell them; tell them; then tell them what you've told them." A construction article might be arranged as follows: Introduction, Theory, Construction, and Alignment and Adjustment, concluding with a wrap-up of results.

The title and opening paragraph are extremely important! If you don't convince the reader in the beginning that he *should* read on, the chances are he won't. Illustrations and photos shouldn't be overlooked, either. An article without either one can certainly appear to be dry . . . even if it isn't.

When writing, remember that *73* is an informal hobby magazine, and that you're writing for some friends. Don't be a stuffed shirt . . . keep away from "the author," and use the first person ("I"). "I fastened the nut" is better than "the nut was fastened." Write naturally in short, simple sentences, starting a new paragraph with each new thought. Avoid unnecessary abbreviations. Use subheadings for each new section to provide signposts for the readers. Dictionaries are too inexpensive these days for there to be any excuse for misspelling; look it up. (You'll never catch *us* doing it . . . we're quite infalable.) Minimize math. It is rarely necessary in *73* articles and scares readers. While most readers can use simple high school algebra and trig, they don't want to. They prefer practical circuits or practical approaches to a subject. Even engineers prefer predesigned circuits, if only as a starting point for their own work. Use math only where it is vital. Avoid footnotes, if possible, and just put your references in the text (it's easier to read that way). And don't forget to give credit when you borrow an idea from someone else. This is important both ethically and legally.

DIAGRAMS

Put all drawings on separate sheets of paper . . . never in the text. We have excellent draftsmen who redraw all diagrams and schematics, so be sure that your sketches are complete, neat, and readable. Put parts values on the schematic rather than in a separate parts list. Use terms "IC1," "R1," and "C2," etc., only if you are referring to them in the text. If a block diagram will be helpful in getting the "big picture," then by all means include one. Label all drawings as Figure 1, Figure 2, and so on. Write a caption for each and include this with the article text so our printers will be able to set the type. Put your name and/or call on every sheet of paper you submit.

All logic diagrams should reflect signal flow from left to right . . . and, if possible, not have signals enter or exit the diagram *except* from the left or right sides, respectively. Logic symbols must be of the *distinctive shape* variety (in other words . . . *do not* use the box symbols of ANSI Y32.14). Also, the logic symbols (gates in particular) should reflect the logic function being performed . . . a schematic with all NAND or all NOR gates usually doesn't.

PROGRAMS, LISTINGS, ETC.

All programs should be well-commented. There should be a column for the address (symbolic, octal, hex, or statement number), a column for the instruction or statement, and a column for the comments (or liberal use of "REMark" statements in a BASIC program). Memory dumps should be used only if a program is extremely long (in such cases you might do well to make arrangements to sell the program for the cost of duplication, or whatever). Flowcharts are fine, too.

Articles on programming should center around the languages of the more popular home computer systems. In other words, an article dealing with programming a particular problem in IBM 360 or DEC PDP/11 Assembly Language would not be appropriate. Machine language, Assembly language, and BASIC articles will be the most sought by our readers. If a program written in another language (such as FORTRAN) can be easily converted over to BASIC . . . or if it contains some interesting techniques or concepts . . . *73* might be interested.

ABBREVIATIONS

Don't make any rash assumptions regarding abbreviations . . . if you have any doubt, be sure to spell them out the first time they're used. We use the NBS-accepted abbreviations: Hz, kHz, MHz, uF, pF, mH, uH, H, W, mW, uW, V, mV, kV, A, mA, uA, dB. Do not use periods or pluralize the abbreviations. Separate them from the number: 10 MHz, not 10MHz.

PHOTOGRAPHS

Good photographs use up a lot of space and make an article much more interesting. If you can't locate an amateur photographer, you should use a professional. The amateur will probably do the job in exchange for a credit line in your article. The professional will, of course, charge you a fee, but the article will probably bring you at least that much more. Photos 4" x 5" are OK, but 8" x 10" are preferred. Instamatics and Polaroids just don't cut it. You'll want an overall photo of the equipment, plus views of any area that will be helpful to the reader who wants to duplicate your effort. Again, captions are separate and can be put at the end of the article text. (Number the back of each photo to correspond with each caption.) Do not use figure numbers for photos.

THE MANUSCRIPT

Use regular typing paper (not the erasable type) and double space your article, leaving wide margins. Number the pages and put your name and call (if any) on each page. Do not type titles, subtitles, or text in all capitals. Underlining a word indicates that it is to be in italics. Keep a carbon copy . . . just in case. Each page of typed copy will be equal to about one sixth of a page in *73*.

Send your article, First Class, to:

John Craig
I/O Editor, *73*
RFD Box 100 D
Lompoc CA 93436
(805) 738-7337

Be sure to enclose a self-addressed envelope in case we have to return it. We'll let you know our reaction as soon as possible. Payment usually takes a week or so and up to a month or more when we have to recheck something. The payment depends on interest, uniqueness, how well prepared the article is, how well known you are, how much work is involved in preparing it for publication, etc. It normally runs between $25 and $40 per page, with the average being about $30. Technical articles normally pay more than non-technical ones. We estimate the length of the article as best we can, and our payment is final. If you think we've made a bad mistake, let us know before you cash your check.

Once the article has been paid for, it belongs to *73*, with all rights reserved. It will be prepared for publication on a schedule determined by the editor. You will receive proofs of the text and diagrams, and should check and recheck these proofs for errors. Your reputation (and *73's*) rests on your care at this point. It is too late for rewriting, so just correct any errors and rush the proofs back. Then begin work on your next I/O article.

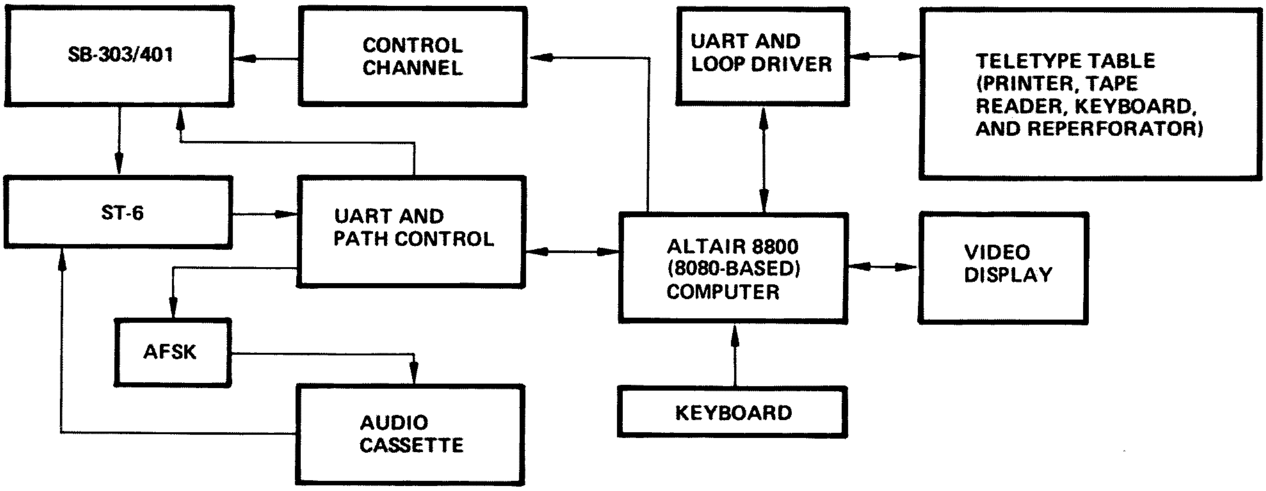
The First Computer-Controlled Ham Station

--Grand Prize winner at the WACC!

Station console. Computer, station control, video display, and keyboard are rack-mounted for ease of operation.



The microprocessor has established itself as one of the most useful and versatile products on the electronic market to date. It is not too surprising that many amateurs are experimenting with and using microprocessors in conjunction with their radio hobby. The applications for microprocessors within amateur radio are as varied as the individual imagination, the best part being that a microprocessor-based implementation of a complex function is relatively simple compared to its discrete component counterpart and is much more flexible. This article will attempt to give the reader an overview of what I've done with an Altair 8800 microprocessor-based system and a radioteletype station. Later articles will be more specific about software and will include construction articles for those wishing to use some of these ideas.

Don's station was the Grand Prize winner at the recent Altair Computer Convention in Albuquerque, New Mexico. His system consists of a Heath SB-301 and SB-401, Altair 8800 with 8K of memory, ST-6, ASCII keyboard, home brew video terminal, and Model 19 (for hard copy). It was the "only totally integrated system" among all the demonstrations set up there. – Ed.

Some Definitions of Terminology

A few definitions are in order before I get too far. These are my own definitions and are not necessarily rigorous.

1. *Microprocessor:* An integrated circuit (sometimes several integrated circuits) which will perform a number of varied operations according to a list of instructions stored in memory; a computer on an integrated circuit. I will use the words microprocessor, processor, and computer almost interchangeably through the rest of this article.

2. *Instruction set:* A list of logical, mathematical or manipulatory operations that a processor will perform on data stored in memory or within the internal register structure of the processor.

3. *Hardware:* The actual collection of electronic components, wire and other assorted stuff that makes up the computer system.

4. *Program:* A sequence of instructions (selected from the instruction set) and data which directs the operation of the processor to accomplish a given task. A program is stored in memory while it is in use.

5. *Bit:* The smallest unit of memory. A bit may be either on or off, logical one or logical zero.

6. *Byte:* Eight bits. The byte has come to be a standard measure of memory. Hang around a couple computer freaks and you will hear one of them ask how much memory so and so has. If the answer is over 8 thousand bytes you should be suitably impressed. If, on the other hand, the answer is some small number like 256 then you should say something like "What can he do with that?" If the number of bytes is given in so many K, for instance 32K, that is the same as saying 32 thousand except that it is easier. By the way, whenever someone is talking about memory, a thousand (or a K) usually means 1024. It's easier to say 16 thousand, or 16K, than 16,384.

7. *Word:* A unit of memory consisting of a somewhat arbitrary number of bits, the number being defined by the particular processor used. It is the number of bits that the processor operates on at any one time (don't quote me on that since there are always exceptions). The most common word size for a microprocessor is 8 bits, or one byte.

8. *Memory:* The medium which stores programs and data such that the processor has access to any word at any time.

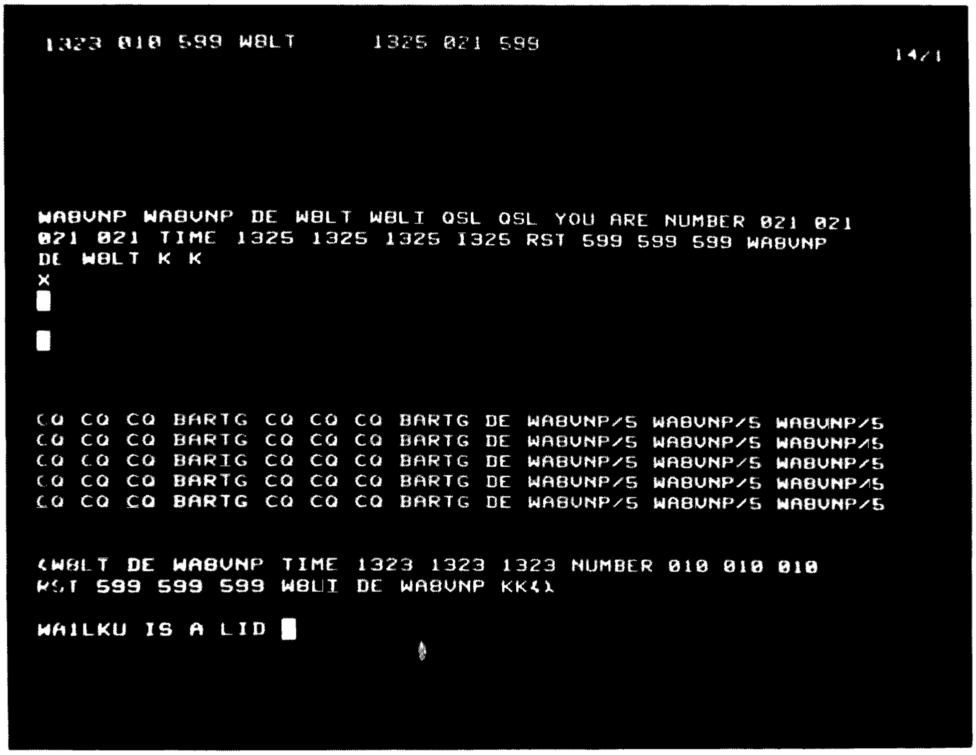
9. *Mass storage:* A medium which is used for long term or large volume storage of information. Examples are magnetic tape, paper tape and magnetic disc. I distinguish mass storage from normal memory on the basis that information stored on a mass storage device must be transferred to normal memory before it can be used by the processor.

10. *Software:* Programs. Programs are called software because they can be modified without too much trouble as compared to modifying a piece of hardware.

11. *Firmware:* The exception to the last definition. Sometimes programs are stored in a special type of memory that cannot be modified by the processor (except in very special cases or if the processor begins to burn). These programs are called firmware because it is not as much trouble to modify a firmware program as it is to modify hardware, but it requires more profanity to fix an error in a firmware program than is normally associated with changing software. See the next three definitions.

12. *ROM:* Read only memory. A type of memory that is programmed during manufacture. The contents of a ROM cannot be changed except by destruction.

13. *PROM:* Programmable read only memory. A read only memory that can be



Close-up of the video display showing, from top to bottom: current log line, receiver area, keyboard entry line (blank except for cursor), and the transmit buffer.

programmed in the field by the user (meaning you). It is more useful to the amateur market than ROM since programming charges for small quantities of ROM (less than several thousand) are prohibitive.

14. *EPROM:* Erasable, programmable read only memory. Same as PROM except that it may be erased by high intensity ultraviolet light and re-programmed. There is also a new type of ROM being introduced which is electrically alterable (which screws up my definition of firmware, but I doubt if anyone who knows about it bothered to read the definitions). I think it is called EAROM for electrically alterable read only memory. The main thing about ROM, PROM, EPROM (and EAROM, I think) is that it doesn't forget what it knows when the power goes off.

15. *RAM:* Random access memory. This type of memory can be read by the processor and modified by the processor. It also tends to forget what it knows if the power goes off unless it is magnetic core memory. Most microcomputers use solid state RAM since core memory is expensive and comparatively hard to use and uses much more power. Still, you will hear people talk about how much core they have even when they mean solid state RAM. Don't bother to correct them – it's a waste of time. I have been corrected many times and still have a tendency to call my memory core.

16. *FIFO:* First-in-first-out buffer. A type of memory buffer which stores information (usually characters) in such a way that the characters are expelled from the memory (when requested) in the same order in which they were originally entered. Many radioteletype stations use such devices to simulate the paper tape punch/paper tape reader combination which can be used to allow an operator to type information ahead of the transmitter.

17. *UART:* Universal asynchronous transmitter/receiver. A circuit which converts serial data to parallel data and vice versa.

The Inspiration

When I first got into radioteletype I never imagined that I would ever need or want anything beyond my RTTY converter (ST-6) and my Model 19 teletype machine. After operating my station for a couple years, I had talked to guys who had video displays, selective call-up, time/date prestidigitizers, UARTs and FIFOs, and all manner of other equipment better than mine. Hardly anyone knew what a Model 19 was except that it made a lot of noise. Pretty soon my ears confirmed the suspicion that a Model 19 is not as quiet as it could be. Then one day some guy told me what UART stood for and how to use one. I decided to build a super station.

I made a list of all the features I wanted to include in my ultimate teletype station. The major items were to be a video display, a solid state keyboard, use of UARTs and FIFOs, selective call-up, time/date generation and a message board. Minor items were added, deleted and modified almost daily at the outset of the design project.

The first major sign of trouble appeared when I was considering methods to edit a 72-80 character line down to 64 characters so it would fit on my display. The most obvious idea is to break the line on a space if it occurs near the end of the line. For this purpose one has to consider the line feed character to be equivalent to a space. I was talking to some station up in Nova Scotia and telling him about this when I noticed that he, like many amateurs including myself from time to time, had the habit of ending a sentence, sending 10-20 periods (or dashes), and then beginning a new sentence. This could result in split words or lines beginning with umpteen punctuation marks if I simply looked for spaces to break my lines on the display. It began to look like I would have to settle for some funny looking print occasionally. I was willing to accept that, so I plunged ahead. But, by the time I was actually near the point of building anything, the designs had gotten to be so complex and inflexible that I wanted to wander onto I-71 pulling my Model 19 right behind. Then I heard rumblings about the eventual legalization of ASCII for use on the amateur bands and all but gave up on the project.

One day, in the depths of despair, I read an article on recent microprocessor breakthroughs which had brought prices down to affordable levels. It didn't take too long to realize that by simply interfacing the various com-

ponents of my station to a computer, I would be able to simulate all of the desired features by writing appropriate software. In addition, I would be able to write programs that would do all sorts of other things I had never even considered building because of their complexity (e.g., almost automatic contest operation). Time/date and selective call-up would be trivial. A FIFO could be simulated by software with the addition of elaborate editing capabilities (I don't type so well). The legalization of ASCII would cause no problems since I could copy any code (including Morse) by doing the appropriate code conversion. I could even have the system whistle "Dixie." Such a deal.

The Realization

The block diagram shows the configuration that I finally decided to use. It is not as optimum as it could be, since it would be desirable to have a completely separate interface for the cassette recorder. However, it is reasonable to use the RTTY demodulator and AFSK generator for storing data on an audio cassette since it involves no additional construction other than a switch or two. I needed to get something going to fill the time it would take to get a dedicated cassette interface going. Besides, using normal AFSK for cassette recording will probably turn out to be one of the best ways for amateurs to exchange software.

The keyboard is a solid state keyboard (many types are available from the various surplus houses) which generates a seven bit code (ASCII). The interface for the keyboard is a simple parallel input port and will be described in one of the later articles.

The Heath SB-301 and SB-401 are monitored and keyed through the ST-6 demodulator and a UART. A control channel allows the processor to select the shift, reverse the shift, select the speed of the UART, turn the transmitter on and off, and send make break or narrow shift CW. It is pretty simple, consisting of the UART and some latches to provide the necessary control.

The video display is a home brew display and is the most useful item in the system next to the processor itself. It will display 29 lines of 64 characters per line in both upper and lower case, plus a few Greek symbols. The memory of the display is large enough to hold 32 lines of information but I have displayed only 29 lines to avoid uncomfortably close line spacing. The processor treats the display as normal memory rather than as an output device, and can read from or write to the display memory at a very fast rate, the actual rate depending on the program controlling the read or write functions. An upper limit for the transfer rate is about 2 million characters per second, the typical rate being closer to 100,000 characters per second. The high read/write speeds mean that there is no need to build extra hardware for scrolling the display – one simply writes a short program that reads each character of the display and re-writes it on the next line up. Scrolling the entire display then takes about 50 milliseconds of processor time. Another advantage of this technique is that the display can be partitioned into several sectors and each sector can be scrolled independently of the other sectors.

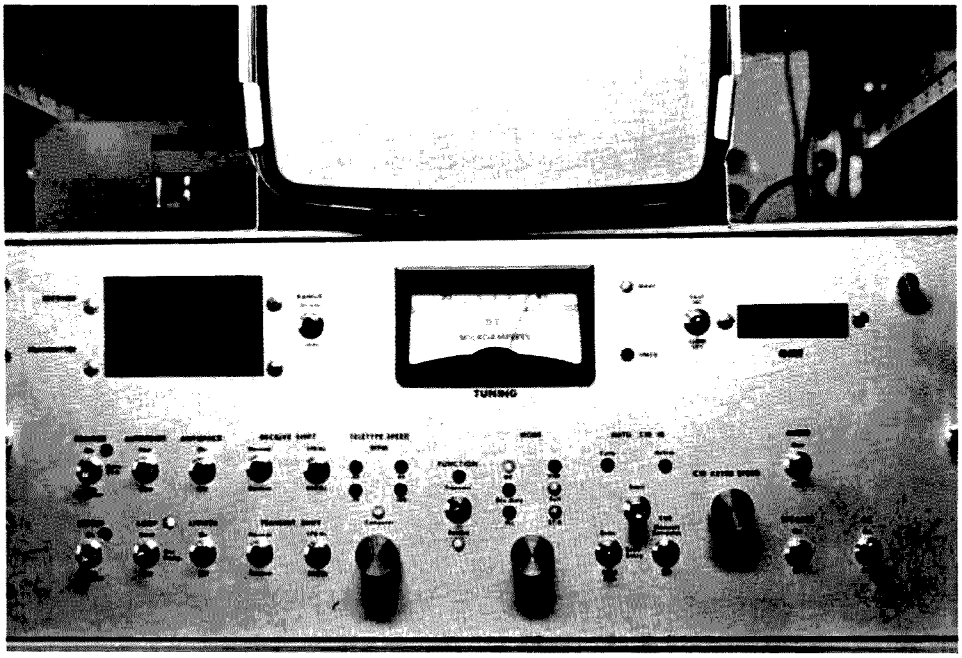
Another feature of the display is that each character can be controlled on an individual basis to produce a black character in a box of white. I use the video inversion feature for displaying cursors, which means that I can have as many cursors roaming around as I desire.

The teletype equipment (my old Model 19) is interfaced through a UART and simple loop driver and sensor. I use the teletype for producing hard copy of my programs, my logs, and for printing teletype art. It also serves as an excellent backup system for making and reading paper tapes in case the cassette recorder decides to give up the ghost.

The Sting

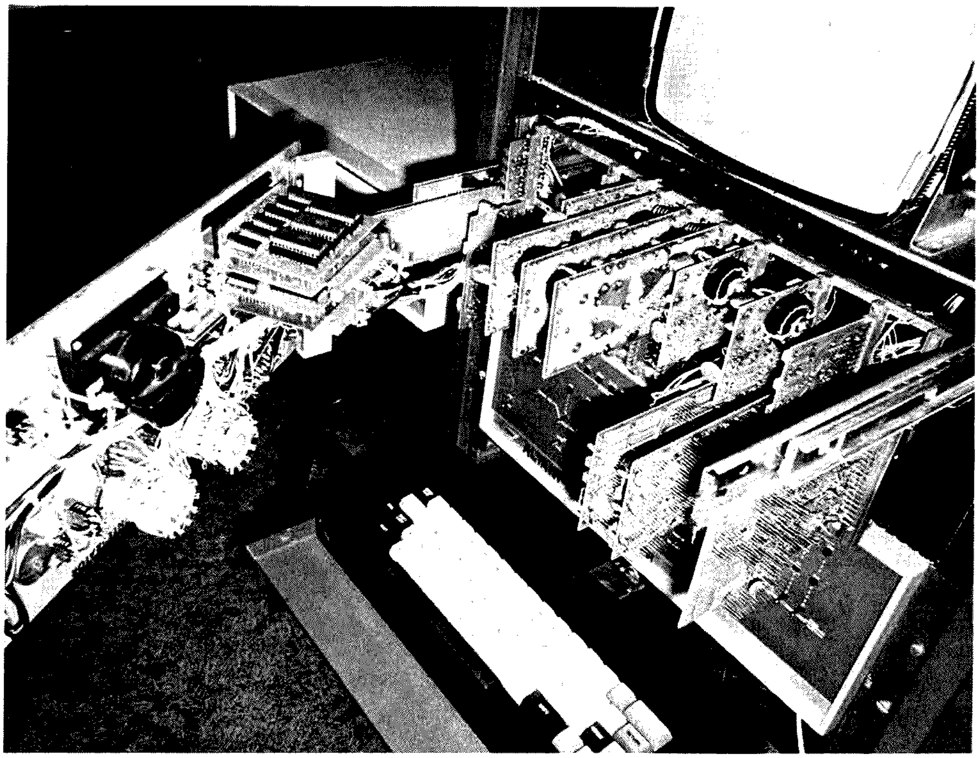
The first practical use I made of the system was as an operating aid in the BARTG RTTY contest during the last weekend of March. I had just finished putting the system together and had gotten a resident assembler running (a resident assembler is an extremely valuable programming tool – watch for articles on programming) when I was invited to bring my system to Albuquerque as a display entry in the Systems Demonstration Contest of the World Altair Computer Convention. It happened that the convention was the same weekend as the BARTG contest. In four long evenings I wrote a contest program that would enable me to operate the contest from the convention while I was devoting most of my attention to telling people about the system.

The processor "listened" to the receiver through the ST-6 and UART. When I was tuned to a valid RTTY signal, the information was edited



Front panel of station console.

and displayed in one area of the video display. If I saw a station that I wished to work, I typed in the call of that station. The computer would instantly tell me if I had already worked the station or not. At the same time it would enter the call of the station, the current time, and the contact number on a line of the display that I had reserved for developing log entries. The only other piece of information that I needed to type was the signal report I wished to send to the station. By using special two letter commands, I could have the computer call the station (or answer him if he was calling me), send the entire exchange, tell him that I QSL or ask him to repeat the exchange, or tell him that this was a duplicate contact. Other two letter commands allowed me to request the computer to send CQ and call QRZ. All of the text that the computer generated (which was complete with callsigns and carriage control) was displayed in another area of the screen. Upon completion of a contact the computer would turn on the printer and print a hard copy of all information required in the contest log. If a contact was started and not completed, then no log entry was made. The only information saved in memory after a valid contact was the callsign and a tag byte to indicate which bands the station had worked so the computer could do duplicate checking, as mentioned above. The computer also handled generation of the CW identification, when necessary.



Interior of station console showing the ST-6 boards, frequency meters, electronic keyer, and interface boards.

The result was that I walked away with the first place prize in the system display contest, a floppy disc drive. Needless to say, I have altered my plans concerning construction of a separate cassette interface and will be devoting my time to writing software to utilize the disc drive as my mass storage device.

The Implications

So far I have only scratched the surface of the many possibilities for use of a microprocessor in the RTTY area alone. Other obvious uses for microprocessors within amateur radio include repeater control, CW reception and transmission, antenna control (for OSCAR or moonbounce especially), and who knows what else. A less obvious but equally or more useful application is digital filtering. Slow scan to fast scan conversion would also be another interesting possibility.

If you or your club has been doing work with microprocessor applications within amateur radio (or in any way related to amateur radio), I'd be interested in hearing about them. There are many ideas and techniques for using microprocessors rolling around out there, and I would like to help get them into print. Better still, write an article about your stuff so others will know what you are doing. ■

The Which Chip Dilemma!

--4, 8, 12, or 16 bits: pros and cons

I have had my computer operational for nearly four years now, but there are not many people who know what kind of computer I have – I don't tell them. It is not that it is such a bad system; in fact, I have a floppy disc operating system with a TV display (including color graphics) and ASR33 Teletype for hard copy, and an almost-running audio cassette interface. I have programs that play tic-tac-toe and Life, and that allow me to paint pictures on the TV set with a joystick or to make music through the cassette player amplifier. I keep the local computer club mailing list on disc, and have programs to sort the file and print labels. I have two different text editors and several assemblers. But when I tell someone that I have a 4004 system, they look at me and think or say, "But that is a four bit processor. It is only half a computer."

Now, I will concede that four bits is only half of eight bits, and most of the microprocessors around are eight bit machines. But I dare say that my system is twice the computer that most of the eight bit systems I have seen are. My point is that to judge a computer solely on its word size is like judging a person solely on his national origin. I call it bigotry. This may be more evident in the following example: The IBM 704 of the 1950s had a 36 bit word; the IBM System 370 of our time has a 32 bit word. Yet the 370 is by no means 11% less of a computer than the 704. The real measure of a computer is what it can do and how well it can do it. True, the word size is significant, but less so than CPU architecture, the instruction set, the kinds of addressing modes, how the CPU interfaces to the outside world, and what else goes into the system. In this article we will consider some of these criteria, and compare some of the popular micros in this light.

Since the subject has already been broached, let us consider word size first. There are four standard word sizes in the available microprocessors: 4, 8, 12, and 16 bits; the bit-slice bipolar components are beyond the scope of this article. Each size has its advantages and disadvantages. First it should be noted that the optimum word size for a small computer instruc-

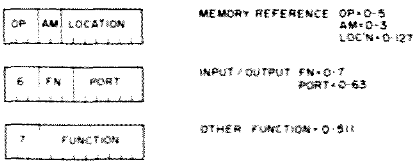

Fig. 1. 12 bit instruction word (PDP-8).

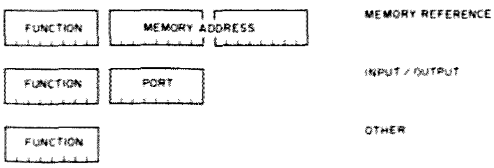

Fig. 2. 8 bit instruction word (8080).

tion is around 12 bits. This permits a few instructions direct access to a small amount of memory, and gives a generous number of bits to the instructions which do not reference memory directly. These are effectively allocated in the PDP-8 minicomputer (and the Intersil 6100, which is the microprocessor version of the PDP-8), as shown in Fig. 1. Three bits are the operation code (that part of the machine language instruction which tells the processor what to do with the data) in memory reference instructions, or serve to distinguish the non-memory reference instructions; two bits define the Addressing Mode, discussed later; the seven remaining bits select one of 128 words in memory. There are six memory reference instructions. Of the two remaining three bit codes, one defines the input/output (I/O) instructions, for which nine bits determine eight different operations on any of 64 different I/O devices (or "ports" as they are sometimes called). There remain yet 512 different possible op codes for the instructions which refer neither to memory nor I/O, though not all of these are meaningful in the PDP-8 instruction set.

The 16 bit computers allow more different instruction op codes for the memory reference instructions and/or a greater instruction address space (the number of memory locations a single instruction can reach) because of the larger word size, but there are wasted bits in the non-memory reference instructions (with only 12 bits the PDP-8 does not use all of the available combinations). The eight bitters, on the other hand, efficiently use the op codes for the non-memory instructions, but there are not enough bits to address a reasonable amount of memory in a single word

Fig. 3. Immediate addressing (8008).

instruction – two or more words are required for this purpose, as shown in Fig. 2. The four bit computers cannot contain their instructions in a single word of four bits; most of them use eight bit memory for instructions and four bit memory only for data.

Twelve bits is not a convenient size for data. Only numbers less than 4096 may be stored in a 12 bit word, so useful numbers often require two words in memory (good for numbers to 16,777,215). Two alphanumeric characters may be stored in one word if they are limited to capital letters, numbers, and a few standard symbols, but if you wish to process the full ASCII character set with lower case and control characters or if (heaven forbid!) you wish to process EBCDIC, then only one character can be fit into a word and the other four or five bits are wasted.

When most of the data to be processed are text characters, an eight bit processor is much more convenient, since each data word holds one character with minimal waste. But the problem with numbers is worse with eight bits than with twelve – the maximum number size is only 255, and two eight bit words still are limited to numbers less than 65,536 (although that is adequate for many needs).

A 16 bit CPU, as we have mentioned, gives more flexibility in the memory reference instructions and also permits a single word in memory to hold numbers to 65,535 or two text characters.

While it would appear at this point that there is no use for a four bit processor, it

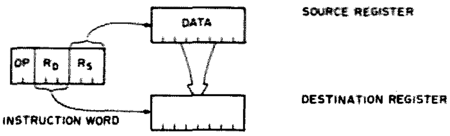

Fig. 4. Register addressing (8080).

actually turns out that when most of the data are decimal numbers or one and two bit status and control signals, a four-bitter is more efficient in processing them. This is because when small pieces of data are buried in larger words, more computer time is required to isolate the data for processing. Thus, four bit processors are ideal for calculators (most calculators these days are actually four bit microprocessors, programmed for the calculator functions) and for logic replacement systems such as process control. The decimal arithmetic capability turns out to be so important in microprocessors that most 8 bit CPUs and even one 16-bitter (National's PACE) have special instructions for this purpose, but the user is stuck with an even number of digits, and decimal multiplication and division is difficult in anything larger than four bits. Consider the advantage of doing all your arithmetic in decimal (people think in decimal, not binary!) so that number conversion routines are not needed. Since more than one memory location is required for any number greater than one digit anyway, you have "infinite precision" (as large a number as you care to handle) at no extra cost.

Another important way to distinguish microprocessors is by the number and quality of CPU registers. In general, more registers result in more compact programs which execute faster. This is because the data for an instruction is already in the CPU, and does not need to be fetched from main memory. The instructions need only a few bits to identify a register, but a whole address is often required for memory data. On the other hand, a few general purpose registers may be more useful than many scratchpad registers which can only be used for loading and storing data. The F8 has 64 scratchpad registers, but only 12 of them are directly accessible to the program, and the others may only be accessed through an indirect address register. This is not as useful as, say, only 32 bytes of scratchpad which can be directly accessed by an instruction (as in the RCA COSMAC CPU), which in turn is less useful than four general purpose accumulators which can be used for calculation and/or index registers (PACE has four accumu-

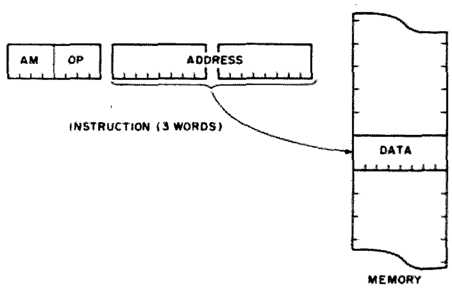

Fig. 5. Absolute addressing (6800).

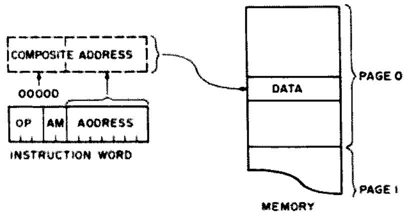

Fig. 6. Base page addressing (PDP-8).

lators, but only two of them may be used for indexing). In a microprocessor the registers may be used for any or all of the following functions:

Accumulators. Arithmetic or logical operations may be done on data in an accumulator, and the result returned to the same register in a single instruction. All of the micros have at least one accumulator. Some have more than one.

Data Memory Pointer. Most of the micros have at least one register which can be used to address memory for data. If the word size is less than the memory address size (as in the eight-bitters), two or more registers may be combined to form an address pointer, or the data pointer may be a double length register. If there is no data pointer (as in the PDP-8), then the CPU *must* have an indirect addressing mode into main memory to handle computed addresses. Often, if the CPU has an indexed addressing mode, the index register(s) will serve the data pointer function. Index registers are a more powerful form of memory address pointer.

Scratchpad. Registers which cannot be used as accumulators or memory address pointers are only good for temporary storage of data, and are called scratchpad registers. Not all CPUs have scratchpad registers. Those that do not must use main memory for temporary storage.

Other. Most CPUs collect the various status flip flops into a "status register." It is not useful for anything else and should not be considered in the same light as the other registers. Many of the micros have a memory address pointer which is used as a "stack pointer" (see *Addressing Modes*, below). It is not wise to use the stack pointer for any other purpose (because of interrupt handling requirements), so this register also has restrictions on its utility. A few processors have other restricted registers, usually used in transferring data between registers.

The different *Addressing Modes* available to the CPU are also an important criterion of rank. A CPU with few registers but many different addressing modes may be more powerful than one with many registers but only a few different addressing modes. The addressing mode of a particular instruction defines how the location of the data is to be determined. Like the number of registers, the more different addressing modes a CPU commands, the more powerful its instruction set is said to be. The following are the most common:

Immediate. The data for the instruction is immediately attached to the instruction. For smaller-word machines this data is usually in the next word in memory, making a two word instruction. For larger words the data is often in the instruction word, but it is limited to less than a whole word. Fig. 3 illustrates the format of immediate addressing. Immediate addressing is usually a very convenient way to load constants into CPU registers, so it is available in most processors.

Register. The data for the instruction is in one of the CPU registers. This is usually the fastest addressing mode, and requires the fewest bits, as illustrated in Fig. 4.

Absolute. The data is in memory, and its address is a part of the instruction, as shown in Fig. 5. The size of this address part determines how much of the system memory is "directly addressable." If the address part of the instruction is less than the address space (the total amount of memory the CPU is able to address at any time), then the address is said to be "abbreviated" and is usually further classified by the way the CPU derives that part of the address which is not specified in the instruction. Many CPUs command both an absolute addressing mode and several varieties of abbreviated addressing modes.

Base Page. In small-word machines it is common to divide the address space into blocks which one word or the address part of one instruction can uniquely address. For 8 bit CPUs this block is 256 bytes, so the total memory is divided into "pages" of 256 bytes each. Eight bits of address can uniquely define one of 256 locations in memory, so many addressing modes are related to the memory in each one of these pages. Which page is accessed is determined by the addressing mode. In particular, one of these pages has a page number (the most significant part of the address of any memory location is the page number) of zero. Page 0 is often specially accessible to instructions in what is called "base page addressing," which requires only one byte of address to access the first 256 bytes of memory. Fig. 6 illustrates base page addressing in PACE. Note that some people use the term "direct" to refer to base page addressing.

Page Relative. Another common abbreviated addressing mode uses the CPU program counter (the instruction address) for the page number, and the instruction specifies the location within the page, as shown in Fig. 7. Most micros with this addressing mode use it only for conditional branches, since the program counter usually is in a page of program memory which may not be appropriate for data. If the location to be reached is in the next page, this addressing mode cannot be used, so CPUs with this addressing mode tend to waste either program memory (by starting new routines on page boundaries) or programmer time (trying to fit them all into the fewest number of pages).

(PC) Relative. In this addressing mode, the abbreviated address is added (as a signed number) to the program counter to give the

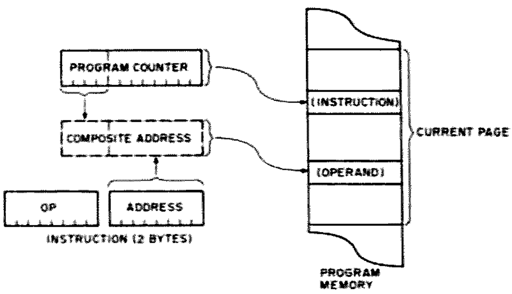

Fig. 7. Page relative addressing (4004).

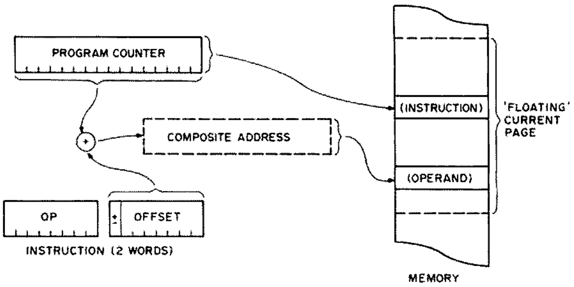

Fig. 8. Relative addressing (F8).

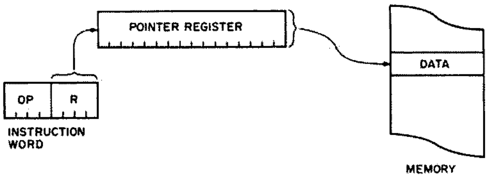

Fig. 9. Register indirect addressing (COSMAC).

operand address (again used only for branches). Thus the page accessible to any instruction seems to "float" around the current value of the program counter, as shown in Fig. 8. This is much more convenient than page relative addressing, since now the programmer need only be concerned with how far the destination is, not with page boundaries. But the cost is generally slower execution (that addition takes CPU time!).

Register Indirect. In this addressing mode the address of the data is in one of the CPU data pointer registers, and not in the instruction at all. As shown in Fig. 9, only one instruction word is required to access any word in memory, but the address must be set up ahead of time. This addressing mode is very useful for processing sequential data, especially if the address register can be optionally incremented (or decremented) simultaneously. Most micros have either register indirect or indexed (see below) addressing, but only a few have auto increment. One form of register indirect addressing with auto-increment and auto-decrement which is included in many CPUs is called "stack" addressing. Usually this is used to save return addresses in subroutine calls and for temporary storage of data. Sequential words of data are stored in (or retrieved from) sequential memory locations by one word instructions. This is slightly less useful than true auto-increment and auto-decrement register indirect addressing, since the programmer does not have the choice of incrementing or decrementing with stack addressing.

Indexed. When abbreviated addressing is combined with register indirect, the result is the indexed addressing mode. The address part in the instruction is added (algebraically if signed, but not all are) to the value in the index register to form the complete address of the data, as shown in Fig. 10. In some processors the address part is not abbreviated, but the index register may be; they cannot both be less than the full address size and still be useful. The indexed addressing mode is very useful for table handling, but more execution time and longer instructions are required for it than for register indirect.

Indirect. Many processors permit the address of the data to be stored in memory, and the instruction contains an abbreviated address pointing to that location. Processors with neither a data pointer nor a full address index register must have indirect addressing to get at tables, data buffers, and other data requiring a variable address. Indirect addressing is almost as convenient as register indirect, but has an additional advantage in that several memory locations may be set up with different addresses which may be accessed at random from different parts of the program. The indirect addressing mode may usually be combined with other addressing modes. Of particular interest is its combination with indexed addressing. Here the index register may be added either to the address part in the instruction to provide variability in the selection of which indirect address to use (called "pre-indexing"), or to the indirect address fetched from memory to provide variability in the data address relative to a given indirect address pointer in memory (called "post-indexing"). Post-indexed indirect addressing is illustrated in Fig. 11. Indirect addressing does not come free: An extra bit in the instruction word must be dedicated to signal it, and extra memory cycles are required to fetch the address.

Aside from what the programmer sees in the CPU, the processors may also be judged on their interface to the outside world. Some micros have several varieties of input and output instructions; others have none. Almost any microprocessor can have I/O devices connected to it that look like memory locations, but those without I/O instructions *must* do it this way. For I/O-intensive applications this may be a nuisance. It also prevents using all of the memory space for memory (if you need that much). On the other hand, I/O instructions use up valuable instruction operation codes, and if the I/O is part of the memory space all of the arithmetic and logical instructions may be used directly on the I/O data (if you feel so inclined; I have yet to see this happen in real programs).

An important distinction sometimes not considered fully is the interrupt capability of the CPU. How many different kinds of interrupt does the CPU support? The 8080 has a single interrupt signal into the CPU, but up to 8 interrupts are easily prioritized in the 8214 Priority Interrupt Encoder, which can provide "vectored interrupt" capability (the interrupting device gives the CPU a memory address indentifying the service routine for that interrupt at the time the interrupt is accepted by the CPU). The M6800 CPU has two interrupt input signals, so that vectored interrupts from two interrupt causes are easy, but for more than that it is much more difficult. Also, the user of the 6800 should be aware that one of those interrupts cannot be disabled and is incompatible with one of the more useful of the CPU instructions. PACE has six vectored interrupts. Unless interrupt service time is critical, vectored interrupts are not essential. In fact, interrupts themselves are not always essential, and some CPUs allow none. I have seen several major programs for CPUs which can support interrupts, but they are not used.

Then there is Direct Memory Access (DMA) for moving data into and out of memory. Only one of the micros (COSMAC) has the DMA logic built into the CPU. A few have DMA controllers in the chip set which supports the CPU. Most of them can be stopped by the peripheral for DMA opera-

LEGEND

MFG *Manufacturer*

TECH *Chip technology*

POWER *Power supply requirements (voltages)*

CLK *Clock requirements: Number of clock inputs,*
- *X On-chip clock may be driven from crystal*
- *S Static — clock may be stopped or run slowly*
- *D Dynamic — clock has minimum frequency*

ADD TIME *Minimum execution time for ADD instruction (some instructions may be faster)*

WORD SIZE *Number of bits; P = Instruction word; D = Data word*

ADDR SPACE *Maximum size of addressable memory*
- *P Program memory (if separate)*
- *D Data memory*

REG'S *Number and kind of CPU registers (one if no digit):*
- *A Accumulator*
- *S Scratchpad, not usable as accumulator or data pointer*
- *X Index, register or data pointer (may consist of multiple separately addressable registers)*
- *G General register, usable as A or X*

ADDRESS MODES
- *@ Indirect (through memory)*
- *± Relative*
- *A Absolute*
- *B (with ± or P) Conditional branches only*
- *D Register Indirect*
- *D± Register Indirect with Auto-Increment, -Decrement*
- *I Immediate*
- *J (with A or P) Jumps only*
- *P Page Relative*
- *R Register*
- *S Stack (i.e., PUSH & POP instructions)*
- *X Indexed*
- *@X Post-Indexed Indirect*
- *Z Base Page*

PAGE SIZE *Number of words in branch page*

X *Number of bits in Index or Data Pointer register*

STACK *Location and number of words; if in CPU, = number of nested subroutine calls*

INT *Number of Vectored Interrupts (parentheses if external encoder required)*

CPU I/O *Number of input and output lines on CPU; single number if bidirectional; otherwise Input/Output*

I/O PORTS *Number of I/O ports addressable by CPU; single number if undifferentiated; otherwise Input/Output*

I/O CHIPS *Peripheral Support Chips available with CPU:*
- *P Parallel I/O*
- *S Serial I/O*

BCD *Decimal arithmetic instructions:*
- *+ Add*
- *- Subtract*

ADD LATCH *Number of address bits which must be latched off the CPU; numbers separated by + indicate multiple time slices*

PRICE *Quantity one price for CPU only; does not include any required support chips. These are published prices at time of writing, rounded to nearest dollar; lowest published price was used; chips meeting speed spec may cost more.*

Blank entries represent information unavailable.

Table 1. Microprocessor comparison.

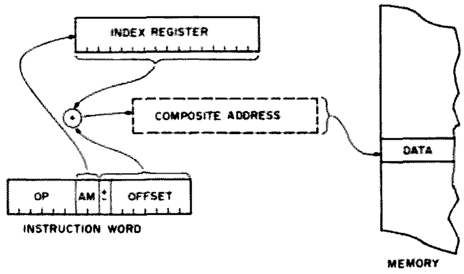

Fig. 10. Indexed addressing (PACE).

tions, and some actually get off the buses when stopped, to make it easier for the DMA logic to work.

Connecting the I/O devices is another problem. The 4004 chip set (my system) has input gates or output latches on every memory device in the family. There are also special I/O devices (4207, 4209, 4211) that connect right on the bus with no extra logic. Motorola came out with some real nifty I/O circuits (6820, 6850) with the 6800, but a certain amount of address decoding is required for all but the most trivial systems. Intel has recently come out with similar circuits, but, as with the 6800 family, plenty of interconnect logic is required. With the 8008 you are on your own. The F8 has lots of I/O right on the CPU and the memory interfaces. Other micros have a few I/O lines on the CPU and require that extra logic for anything over that.

Perhaps one of the more important criteria of distinction to the hobbyist is the interconnection requirements for the processor. How many power supplies are required? Some micros run on +5 volts only; others require +12 and/or a negative supply. If the system uses a 4K RAM memory which needs +12 and -5 volt supplies, a processor with the same requirements is no problem. Some of the processors run on -9 or -12 volts. This could be a nuisance if nothing else in the system needs those supplies. Many of the microprocessors are "dynamic," which means that they require high voltage nonstop clock drivers; even "5 volt, TTL compatible" CPUs may require clocks that swing from 0.2 volts to 4.7 volts, which TTL outputs are not specified to deliver. "Static" CPUs are generally simpler to control because there is only one clock signal to drive, and it can be stopped at any time.

Some of the micros are more easily connected into systems than others, because of the related circuits available from the manufacturers. Is a clock driver available for those odd two phase high voltage clocks? How much extra logic is required to connect standard memory components? What is the fewest number of extra parts that must be added to get a working (special purpose) computer? What happens if I connect a Motorola PIA (M6820 – a good I/O chip) to an 8080 system? Most of these questions are beyond the scope of this article, but they drastically affect how good the resulting computer is.

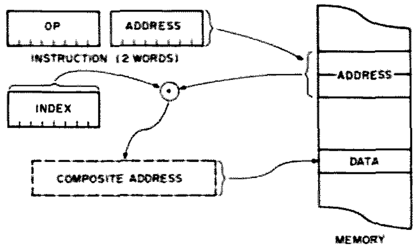

Fig. 11. Post-index indirect addressing (6502).

Table 1 is an analysis of some of the available microprocessors, according to the criteria we have discussed.

As I said earlier, the power of a system is measured largely by the kinds of peripherals available to it. An extremely important peripheral is one providing "off-line storage" in machine-readable form, so that programs can be saved and reloaded without a lot of manual effort. A paper tape reader and punch will do this adequately, but it is slow. Audio cassettes are somewhat faster, more compact, and considerably cheaper. Floppy disc drives are the most versatile for program and data storage, but there does not exist at this time anything for the amateur for less than $2000. This is unnecessary: I bought everything new and spent about $800, but I had to design my own controller.

A second essential peripheral is the human interface. While lights and switches look esoteric, they are not suitable for most programs. The so-called "TV Typewriter" is probably the best human interface you can get for your money. A Teletype with paper tape reader and punch is the cheapest single peripheral to give both machine-readable data storage and the human interface (with hard copy, yet).

Last here, but most important, is the *software*. The computer is worthless without a program. Writing that program and getting it into the computer and getting it to run correctly is not easy. It is harder for some microprocessors than for others. It is harder in some systems than it is in others with the same CPU. Different programmers will find different processors or systems to be easier or harder. But you can be sure all of the good systems (i.e., the ones that are easy to use) represent a lot of programming effort in operating systems, text editors, assemblers, high level language (such as BASIC) processors, and utility programs.

The next time someone tells you that this micro is better than that one, ask why, and for what. I did not mention that I have two operational computers now. One of them has an 8 bit CPU with a powerful instruction set, but I don't use it, because my 4004 system is "better." Better because the peripherals and the software support are better. I also have over a half dozen CPU chips for other processors, but I am unlikely to do more than make toys out of them, because the two systems I have are better. Better because they already have all the connections to memory and power – an operational computer is better than one that is not.

A final note. This manuscript was prepared on my "Half a Computer" using some of my software to edit the text, pull proofs and correct typographical errors. To add or delete a sentence did not require retyping the whole page; the computer did that. If the publisher had wanted, I could have delivered a paper tape to run automatic typesetting equipment. Maybe next year when I can afford a "whole computer" (that's more peripherals, not a different CPU), I will be able to deliver camera-ready copy. Computer power is what the computer can do. ■

Meaningful Conversations with your Computer

-- what those mysterious "languages" are all about

A glance at the advertisements in *73* or almost any other technical rag will reveal a growing number of computer kits, memory boards, and peripheral devices being offered to the home experimenter. The "home" computer field is growing almost as fast as the two meter boom of several years ago. One of the problems always associated with a new field is the tremendous lack of *practical* knowledge possessed by the casual experimenter. The computer freak now has a wide choice of micro kits, input/output devices, and services to choose from, but the big problem remains: How does one COMMUNICATE with his computer? Ah, yes, you have just completed your Super-X microprocessor kit, and plan to use it to store OSCAR orbital data. A simple application? Yes, but there X sits with rows of switches and LEDs, and not calculating a thing. Something is missing – a method of "talking" to, or "programming" the machine, thus enabling it to perform a meaningful task.

The Language Processor

The missing link is the Language Processor, or LP. An LP is a program that allows a computer user to form the unique set of "machine instructions," which are the binary numbers that direct every machine function. The LP is to a computer what the keyboard is to your pocket calculator – it is a man-machine interface that bridges the gap between human requests and machine action. Without a keyboard, your pocket wonder is useless unless you like to collect big IC chips. Without an LP, a computer programmer is forced to form and insert into memory every binary code that forms a program, requiring a knowledge of the internal construction and machine codes unique to every computer.

Programming Your Black Box

A computer performs its task by executing a series of "machine instructions" that reside in the memory of the processor. The ultimate goal of any programmer is to relate the problem to be solved in terms of the machine instructions that the computer understands. This goal may be reached in two ways: by inserting each instruction into memory by "hand," using the front panel switches, after a tedious process of forming the correct codes, or by using an LP to form the codes for you. This LP may be an *assembler, compiler*, or *interpreter*. This article examines, in simple terms, the function of each type of LP, the associated trade-offs, and the benefits of each. Before starting, however, let's take a quick look at how programming works without the LP, bearing in mind that the final goal of any LP is to produce the binary machine code that only the machine understands.

Machine Language

Every computer, be it an IBM 370 or Motorola M6800 micro, has a unique set of "instructions," consisting of binary codes that direct every internal function of the running computer. Most machines are capable of executing certain basic operations, such as moving data to and from memory, addition, subtraction, and shifting (a process of moving "bits" to different locations within the computer). However, the problem is that each machine uses a different code for similar processes, requiring the programmer to know the details of each machine he wishes to use. One "machine language" program for solving the Ohm's Law ($I = E/R$) relationship is shown in Table 1.

The result of the operation expressed in Table 1 is the answer "I" stored in memory location 10, and the remainder of the division in location 12.

Several problems associated with machine language programming are apparent:

1. The code is unintelligible to anyone not specifically familiar with computer "X."
2. A change to the code to fix a "bug" (a common creature around computers) often requires rewriting much of the existing code, especially when more instructions are added.
3. Following the logic of the original program-

	Machine Code	Comment
Start	4830 0000	Fetch "E" from memory
	0722	Clear temporary
	4840 0002	Fetch "R" from memory
	0D24	Perform division
	4030 000A	Save answer "I"
End	4020 000C	Save remainder

Table 1. Typical machine code to solve $I = E/R$. This example assumes that data "E" and "R" were preloaded into the memory.

	Assembly Language		Comment
Start	LH	R3,LOC0	Fetch "E"
	XHR	R2,R2	Clear Register 2 (temporary)
	LH	R4,LOC2	Fetch "R"
	DHR	R2,R4	Divide
	STH	R3,LOC10	Save "1" in Location 10
End	STH	R2,LOC12	And save remainder

Table 2. An assembly language representation of a program to solve I = E/R.

	M6800 Assembly Code		Comment
Start	LDA	A,LOC0	Fetch "E"
	LDA	B,LOC1	and "R"
	JSR	DIVD	Go to Divide routine
	STA	A,LOC2	Save answer "I"
	STA	B,LOC3	and remainder
End	SWI		Done
Divd	******		A software program to
	******		divide, as the M6800 has
	******		no specific divide instruction;
	RTS		Return to calling routine

Table 3. Routine to solve I = E/R on a Motorola M6800 micro.

mer and documentation of the program is difficult, especially when the programmer takes another job.

All computer programming in the early '50s was done in direct machine language – prompting the development of the first type of LP, the *assembler.*

The Assembler – Symbolic Programming Made Possible

The first member of the LP family is the assembler, a computer program that allows machine instructions and operations to be represented symbolically, i.e., in a more human form than rows of numbers. The programmer is still required to know the specific machine instruction set of his computer, but the assembler allows him to refer to instructions by name (or *mnemonic*) instead of number. The end result of an assembly process is a machine language program similar to that in Table 1. The assembler only serves to make the generation of those codes a less tedious process. A sample assembly language program to solve our Table 1 problem is shown in Table 2.

The same program coded for the Motorola M6800 microprocessor is given in Table 3, illustrating the point of how a programmer must know the unique instructions of each machine he wishes to use when programming in assembly or machine language.

Several shortcomings of machine language programming are resolved by using an assembler. For example, changing or correcting the program requires only a "source" change, usually done by changing the punched card in error. The complete program is then reassembled, causing the output of correct machine code. The assembly process removes the requirement that the programmer know in advance how his change affects the code in instructions around the correction. Documentation of the program is easier also, as the symbolic representation of the machine code is understood by anyone familiar with the machine. Software development cycles are speeded up, as correction and modification of programs does not require extensive code changes.

Most microcomputer manufacturers provide an assembler with their micro kits. However, most assemblers require a large amount of memory to function, recalling that the assembler itself is a program coded in the machine code particular to a given microcomputer.

The Compiler – Or, Programming in English

The assembler LP greatly increased the capability of man to talk to his computer, but the basic restriction of having to know internal details and procedures still remained. An ultimate LP was required, one that allowed programmers to function in an English language environment. The first such LP was a language known as *FORTRAN*, a program dedicated to "*FOR*mula *TRAN*slation." FORTRAN is an LP that lets programmers represent problems as they occur on paper or textbooks, in English. This type of LP is often referred to as a "high level language": the higher the level, the more English-like the representation of instructions. Most high level LPs allow the program to contain notation and conventions that would normally be used to describe the problem, thus allowing the programmer to concentrate on the solution of the problem, not the internal workings of a computer. Using our old Ohm's Law example, Table 4 shows what the FORTRAN program looks like.

The power of the high level LP is provided by a very complex and large program. From Table 4 it can be seen that the single statement expressing the formula really requires several machine instructions (Table 1). A single complex FORTRAN statement may produce 50 or 60 machine instructions. (Remember, that's all the processor knows!) The real beauty of a *compiler*, the high level LP, is that the same source program may be run on any machine capable of supporting the compiler. The compiler for each machine knows that the incoming program is in a standard format (as defined by standards committees), so it must produce the unique machine code to solve the problem. It can be seen that each FORTRAN compiler will only run on the machine it supports, but the

```
C         Comment – Divide E by R giving I
C
C
          I=E/R
          STOP
          END
C         That's it – of course other instructions are
C         needed to input the raw data.
```

Table 4. A typical FORTRAN program.

```
1  REM Read E and R, then calculate and print I
2  INPUT E,R
3  LET I=E/R
4  PRINT "ANSWER IS = ",I
5  STOP
```

Table 5. A BASIC program that accepts input from a terminal, calculates the answer, and prints out the result, all in three statements. (Line 1 is a comment; line 5 needs no explanation.)

standard source program (written by a programmer) will be accepted by any compiler. This concept, known as "computer independence," is the foundation of the programming profession. A programmer used to coding IBM 370 FORTRAN can be writing programs on an INTERDATA minicomputer the day he changes jobs, as the LP takes care of the nitty-gritty details of producing the different machine code.

FORTRAN is not the only high level LP. A few seconds spent scanning any computer trade publication will reveal names such as *COBOL* (*CO*mmon *B*usiness *O*riented *L*anguage), *APL* (*A P*rogramming *L*anguage) or *JOVIAL* (believe it or not – *J*ule's *O*wn *V*ersion of the *I*nternational *A*lgorithmic *L*anguage). Each of these LPs has a source input format suited to a particular application. COBOL, for example, is well suited to business applications, such as payrolls, but finds little use in the scientific community.

The Interpreter – A Micro's Best Friend

Compilers are available for all large computers and most minis, but due to their complexity and cost have not filtered into the micro world yet. It often takes several man-years to develop a compiler and write it in assembly language, so it will be awhile before you can load up FORTRAN on your brand X micro and track OSCAR, even though the capability is there to do it in assembly language. Take heart, however – all is not lost. There is an alternative to the compiler available to microcomputer programmers – the *interpreter*. This LP offers most of the advantages of the compiler with one difference – no machine language is produced from the source program. Instead, the interpreter processes the incoming source statements "on the fly," and produces the answer or results by executing a series of built-in routines triggered by the "commands" produced by the programmer. The most popular interpreter is *BASIC* (*B*eginner's *A*ll purpose *S*ymbolic *I*nstruction *C*ode). Take a last look at our example, this time done in BASIC (Table 5).

Hopefully, the above explanations have taken some of the mystery out of the word "programming." A careful look at the microprocessor kit advertisements will reveal what LPs are available for your application. An assembler is required for all but the most simple applications, and BASIC is available for some of the machines – a big plus if you can afford the necessary memory to contain the interpreter. Even machine language programming can be fun on a micro, and there is probably no better way to learn the ins and outs of computer architecture. The programming tricks learned can always be applied to your next effort, even one using a high level LP. So have fun, and GOOD PROGRAMMING! ■

A Baudot Monitor/Editor System

--program listing for the 8080

Richard Whipple
305 Clemson Dr.
Tyler TX 75701

John Arnold W5CUD
RFD 4, Box 52A
Tyler TX 75701

In an earlier *73* article, we described interfacing a Baudot teletype with a hobby computer. Once this hardware interconnection is made, the next step is to develop a software operating system that takes advantage of the keyboard/printer link to the computer. In this article we describe a program called Baudot Monitor/Editor, or BM/E for short. With it you can store, examine, and execute machine language programs using the Baudot teletype. This is quite an important step on the road to full utilization of your computer.

Why a BM/E Operating System?

Entering a program into memory via the front panel switches can be a lengthy and tedious process. Loading a three or four hundred byte program by hand will just about end the pleasure of owning a hobby computer. The limited usefulness of the front panel as a functional I/O device can be traced to the restriction of lights and switches to two states, i.e., "on" and "off." Thus entry must be in binary notation, which is perhaps the least efficient system for human use. The more satisfactory octal or hexadecimal systems cannot be used, since they require eight and sixteen states respectively. Adding a Baudot teletype can be viewed as a way of expanding the number of I/O states available to the user from two to sixty-four (upper and lower case characters). BM/E is in a sense a translator from the internal binary form to external octal format on the teletype. In addition, having the set of letters and symbols available opens up the possibility of developing a higher level language whose instructions can be entered in English words and phrases. The computer can thus be made to function on a more human level. BM/E is just a start on the path to such a higher level language, but it is an important step for someone who wants to learn about computers from the ground up.

Letter Command	Name	Description
D	Dump	Outputs contents of consecutive memory locations in octal
L	Load	Permits storing octal instructions in consecutive locations
E	Edit	Single locations can be examined and, at the user's option, changed
M	Message	Places the computer in a mode that echos the keyboard on the printer
X	Execute	Starts program execution at a specified address

Table 1.

Understanding Octal Number Representation

Before detailing the operation of BM/E, a short explanation of octal numbers should be made. As already noted, computers use binary format to represent instructions and addresses. Long strings of 1s and 0s, though handled readily by a computer, are difficult for humans to work with or remember. For instance, to specify an instruction at a certain memory location, one would have to write:

Address
0101011011001110
Instruction
11001101

Now suppose you were writing a 500 or 1000 byte program using this binary notation — I wonder which would run out first: your patience or the paper supply?!

Enter "octal notation" to save the day! By expanding the number of symbols from two to eight, the complexity of the binary representation can be reduced considerably. The example above can be written:

Address
126 316
Instruction
315

The improvement from the human standpoint is obvious.

The rewriting of a binary number in octal is accomplished in the following way:

1. Separate the binary number into three digit groups beginning at the rightmost digit.
2. Use the chart below to give each group its octal value.

Binary	Octal
000	0
001	1
010	2
011	3
100	4
101	5
110	6
111	7

3. If the leftmost group has less than three digits, just consider that it is prefixed as required with zeros.

Example:
01010110
(Binary)
1 2 6
or
126
(Octal)

Instructions and data for an eight bit computer such as the Altair 8800 can be represented as a three digit octal number ranging from 000 to 377. A sixteen bit address is most easily represented by two octal numbers obtained by first splitting the sixteen bits into two eight bit groups.

Example:
0101011011001110
(Binary)
01010110 11001110
(Split Binary)
1 2 6 3 1 6
126 316
(Split Octal)

Split octal address representation is useful because it fits the format of multibyte instructions used by microprocessors like the 8080 and 8008. The left octal number is referred to as the page, while the right octal number is the location of the given page. The example address would be stated as "location 316 on page 126 of memory." Thus, in a 65,535 word memory; there are 377 octal pages with 377 octal bytes per page. In further discussion of BM/E, split octal addressing will be used exclusively.

Sometimes it is necessary to convert an octal number to its equivalent. Suppose the three octal digits are given by XYZ. The decimal value can be calculated using the expression:

Decimal Value =
$X \cdot 64 + Y \cdot 8 + Z$
Example:
325 octal =
$3 \cdot 64 + 2 \cdot 8 + 5 =$
149 Decimal

To convert to decimal a 16 bit address written in split octal, first convert the page and location separately as given above. Then use this expression to complete the calculation:

Example:
025242 Split Octal
025 Octal =
$0 \cdot 64 + 2 \cdot 8 + 5 =$
21 Decimal
242 Octal =
$2 \cdot 64 + 4 \cdot 8 + 2 =$
94 Decimal
025242 Split Octal =
$21 \cdot 256 + 94 =$
5474 Decimal

D (Dump octal): This mode provides a listing of consecutive memory locations beginning at an address specified when the mode is first called. Listing continues for a specified number of eight byte lines. After entering this mode from the Monitor, the computer prints a colon prompt to indicate it needs the starting address. The user enters the six digit split octal starting address. The computer responds with a SPACE and awaits user entry in octal of the number of eight byte lines desired.
Example:
!D:010000 002 CR&LF
010000 110 123 204 315 112 010 365 325 CR&LF
010010 325 306 214 176 361 321 125 115 CR&LF !
After dumping two lines as required, the system returns to the Monitor and awaits another command. Notice that only the address of the first byte of each line is printed. This produces a quicker and denser listing. The addresses of the remaining bytes can be easily obtained by counting in octal from the known first byte address.
L (Load octal): In this mode the user can store octal data into consecutive memory locations. After entering this mode, a colon is printed to indicate that the computer needs a starting address for the load. When the address is entered, the computer echos the starting address and waits for the user to enter the first data byte. After the entry, the computer will issue a SPACE and wait for entry of the next data byte. A new line and the current address are output after eight bytes are entered. Return to the Monitor at any time is accomplished by typing a BLANK.
Example:
!L:004000
004000 101 102 103 115 126 135 315 246 CR&F
004010 226 (Blank Key)
!
E (Edit): The E mode is used to examine and, if desired, change specific locations in memory. After entering this mode from the Monitor, the computer prompts with a colon. The user then types the address to be examined. The computer outputs a SPACE plus the contents of the specified location. At this point the computer waits for the user to type either a CARRIAGE RETURN if no change is desired, or a minus sign if a change is wanted. In the latter case, the new data byte is entered following the minus. The new octal value is stored at the specified location, then re-examined and printed again as a check to be sure it has been changed. The system remains in the E mode until a BLANK is typed.
Example:
!E:010000 123-321-321
:010000 321 (Carriage Return)
:(Blank)
!
M (Message): This is simply an echo routine so that the keyboard/printer can be used as a typewriter. In this mode, a CARRIAGE RETURN produces an automatic LINE FEED. Return to the Monitor is accomplished by typing the BLANK key.
Example:
!M THIS IS A TEST. (Blank)
!
X (eXecute): This mode permits execution of programs already stored in memory. After entering the X mode, the computer will type a colon and await entry of the starting address of the program to be executed. To actually begin execution, a CARRIAGE RETURN must be typed. Any other character will cause a return to the Monitor.
Example:
!X:012000 (Carriage Return)
Program execution continues at 012000

Table 2.

BM/E uses octal notation to store and examine data in memory. Instructions and data are written as 3 digit octal numbers. Addresses are written in split octal with no separating mark between page and location. Although octal might appear strange at first, its resemblance to decimal will encourage your quick adjustment to it.

Basic Structure of BM/E

BM/E has two levels of operation: the Monitor (highest level) and the Editor (lowest level). Upon entering BM/E, an exclamation mark is printed to indicate the

000000	061	377	001	303	021	000	076	010
000010	315	215	001	076	002	315	215	001
000020	311	315	006	000	076	015	315	320
000030	001	076	037	315	215	001	315	304

Routine	Function	Calling Address
CRLF	Outputs a Carriage Return followed by a Line Feed	000006
BDBIN	Inputs a Baudot number from the keyboard and converts it to binary in register A	000111
BINBD	Outputs binary value in A on the printer; the binary value must be 7 or less	000160
OCTIN	Inputs 3 octal digits from keyboard into A	000202
OCTOUT	Outputs the value of A as 3 octal digits	000241
ADRSIN	Inputs 6 octal digits from keyboard into registers H and L	001125
ADRSOUT	Outputs the value of H and L in split octal	001136
INPUT	Inputs the Baudot value from the keyboard into A	001147
OUTPUT	Outputs a Baudot value on the printer	001215

Table 4.

monitor level is in effect. From the Monitor, entry is made to one of the Editor levels by typing a one letter command. The Editor mode includes the commands shown in Table 1.

Some of the Editor modes have a specific job to perform and afterwards return automatically to the Monitor level. Other Editor modes are terminated by the user when he strikes the BLANK key on the teletype. To change modes, it is necessary to first return to the Monitor and then select the new Editor mode. A more complete description of each mode is shown in Table 2, including example output. Underlined portions of the output were entered by the user, while the remainder was produced by the computer. To simplify operation, the computer controls the printer case (LTRS and FGS).

Bringing Up BM/E for the First Time

Loading the 500 or so bytes of BM/E for the first time will require exercising the front panel switches and your patience. The switches will survive, but, as for your patience, that depends on how interested you are in BM/E. Loading it once by hand is enough, but without some form of nonvolatile mass storage you may be forced to load it each time the system is down. There are two directions to go here: cassette tape or punched paper tape. For the long term, the cassette is probably the best choice. It is much denser and faster. One problem so far has been the lack of agreement on just what type of cassette system to use. Various efforts have been instituted to bring about standardization, but as of this writing there are still obstacles to general acceptance of any one system. The so-called "Kansas City Standard" system appears well on the way, but it is not yet in general use. In our own system we have used a Suding cassette interface for nearly a year without a single bad load. We were attracted to the system because it was FSK and used the wide frequency shift standard of amateur radio (2125 Hz-2975 Hz). Information on a Suding interface can be obtained from The Digital Group, P.O. Box 6528, Denver CO 80206.

Baudot teletype users also have the option of bringing paper tape on-line as a mass storage medium. An article in an earlier issue of *73* described the use we have made of Baudot paper tape equipment. Although not as dense or fast as cassette tape, it is convenient to use, especially for short programs.

In addition, if you have your Baudot teletype on-line already, no additional interfacing is required to use paper tape equipment. It should also be pointed out that paper tape is already standardized, so interchange problems are minimized. Regardless of the system you use, a nonvolatile storage medium is a necessity in a hobbyist system.

Table 3 is an octal listing of BM/E in the Dump format of BM/E. The program is intended for an 8080-based system. As given, it utilizes the software I/O described in the previous article. If you are using a serial I/O board, your required I/O routines should be loaded at 001147 input and 001205 output. Neither routine should exceed 38 bytes.

When the program is loaded, simply examine 000000 and hit RUN. An exclamation point typed on the printer indicates BM/E is operative. You can load programs anywhere above 002000. You should exercise the various Editor modes to be sure all is well.

Table 4 gives the address of various routines in BM/E that can be called by your external programs. For instance, suppose you want to output the A register in octal format. Simply place a CALL to 000241 at the appropriate place in your program.

The authors will supply a source listing of BM/E along with a Suding cassette, "Kansas City Standard" cassette, or punched paper tape (5 level binary format) for $7.50 postpaid. In your order please specify which type cassette or paper tape. Orders should be addressed to: BM/E Tape, Rt. 4, Box 52A, Tyler TX 75701.

With hard copy on your Baudot teletype and BM/E as an operating system, you should be able to greatly expand your software capabilities. ■

Fig. 1. IC1: SN74132N. IC2: SN7486N. IC3: NE556. All resistors are ¼ Watt, except for the one which is ½ Watt, 39 Ohms. Power supply current is approximately 70 mA.

A Logic Probe You Can Hear

--good not only for the blind

The most serious shortcoming of conventional logic probes is the need to watch for signs of a change. It's not always convenient to be watching the probe during a test.

This unit gives an LED indication of the static state of the line under test. When the LED is lit, the line is logic state "1." Any logic transition which lasts at least 50 nanoseconds is detected, and an audio beep is generated. Both a "1" to "0" and a "0" to "1" transition are detected.

Construction

My unit is built on a perforated epoxy board. Discrete components are mounted on a 16-pin header which plugs into an IC socket. Sockets are mounted by installing printed circuit board eyelets under pins 7 and 14. Each eyelet is peened in its hole by using opposing automatic center punches. The sockets are mounted, and pins 7 and 14 are soldered to the eyelets. The rest is a simple wirewrap job.

It is possible to run the device from batteries, although the current is a bit high (about 70 mA). Rather than use batteries or steal power from the circuit under test, I decided to include a small power supply. Everything is mounted in a small phenolic box of the type carried by Radio Shack.

Operation

There is no special procedure. Simply connect the input to the line to be monitored, and a ground between this device and the one under test. Once connected, an audible beep will be heard whenever the line pulses or changes state. The LED indicates the line's static state.

Theory

The input is squared by (Schmitt) IC1A, which is also the LED driver. IC1B and IC1C provide a delay before applying the signal to the exclusive OR gate, IC2. When the input changes state, the two signals applied to the exclusive OR gate will be different for a period equal to the delay through IC1B and IC1C. The gate will pulse low for this time. After inversion by IC1D, the positive pulse is applied to the first half of the NE556 (IC3). This half is wired as a one shot with a duration of approximately one half second. The output of this one shot is applied to the second half of IC3, which is wired as an audio oscillator. When the one shot is active, it turns on the oscillator, which in turn drives the speaker. Changing C1 will adjust the duration of the beep; C2 determines the output tone.

Troubleshooting

During initial wiring, leave out the jumper between pin 5 of IC3 and pin 10 of IC3. Check the power supply to be sure it is +5 V. Plug in IC3. The oscillator should be heard running. This is a good time to vary C2 if you would prefer a different tone. After the tone is working properly, connect the jumper between pin 5 and pin 10 of IC3. Plug in IC1 – but not IC2. Touch pin 12 of IC1 momentarily to ground. The oscillator should beep for approximately one half second. C1 can be adjusted to vary the beep duration.

The LED should be lit. Touching pin 2 of IC1 to ground should make the LED go out. Insert IC2 and test the complete unit. Short the input (pin 2) of IC1 to ground. The LED should go out and the oscillator should beep. Remove the short and another beep will occur.

If you want to test its ability to capture a pulse, I suggest wiring a one shot (such as an SN74121) as a switch deglitcher. This device will capture the pulse every time the switch is pushed. ■

How Computer Arithmetic Works

-- do-it-yourself experiments

The easiest and most inexpensive way to get started in computers is to begin with inexpensive, easy to use, fundamental building blocks. These fundamental blocks can be used initially for educational purposes to promote understanding and confidence, and later combined to form a fundamental computer.

The arithmetic logical unit (ALU) is a fundamental part of a typical computer system. The ALU is inexpensive, is easy to use, and may be operated independently or in conjunction with other devices. This article uses the ALU as a stand alone device in order to demonstrate computer operations such as addition, subtraction, and complement. All necessary details and related information are given so that the experimenter can learn fundamental computer arithmetic.

The dollar outlay required to procure the parts and equipment needed to perform the experiments given in this article should be less than $12, not counting a breadboard or PC board.

The Parts and Equipment Required

The parts and equipment needed to perform the experiments in this article are as follows:

1 – 5 V power supply
1 – 74181 integrated circuit
1 – breadboard, perforated board, or homemade PC board
1 – voltmeter or 4 LEDs

A 5 V power supply may be purchased in kit form from James Electronics for $9.95, or a wired and test supply may be purchas from Micro Digital Corp., f $24.50. A 5 V power supp may be built in breadboa fashion, for about $6.00, using the circuit described Fig. 1.

The 74181 ALU is av: able from many sources, su as Poly Paks, James El tronics, International El tronics Unlimited, and othe for less than $4.00. See ads in this issue for curr prices. An illustration of pin connections and c

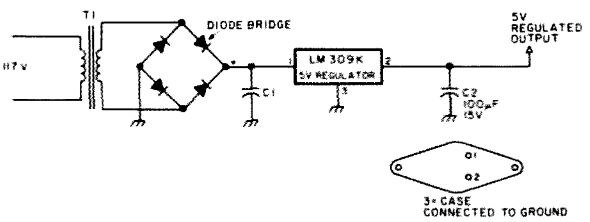

Fig. 1. Simple power supply. T1: 12 V, 1 A (Poly Paks 92CU2474, $2.95). Diode bridge: 2 A, 50 V epoxy (Poly Paks 92CU1346, $.69). C1: 3500 uF (minimum), 25 V dc (S. D. Sales, $.79). C2: 100 mF, 15 V dc (James Electronics, $.24). LM309K: 5 V regulator (Poly Paks, $1.50). Total power supply parts cost: $6.17.

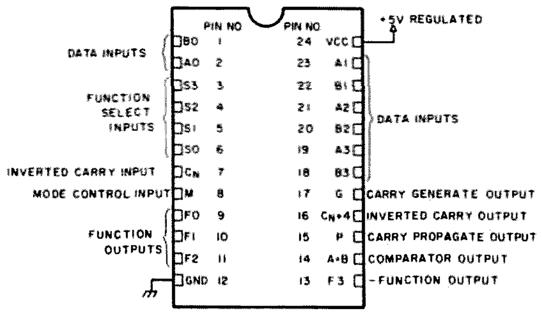

*Fig. 2. 74181 pin connections, top view (*The TTL Data B for Design Engineers, *Texas Instruments, Inc., 1973, p. 3*

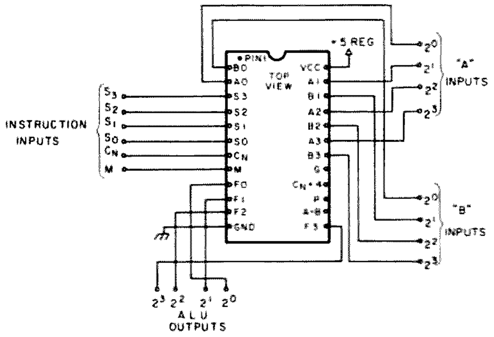

Fig. 3. Basic experimental setup. Bring instruction inputs out to left as shown. Bring function outputs either out to bottom or out to left, in order shown. Connect +5 V regulated power supply to pins as shown. Bring inputs out to right as shown.

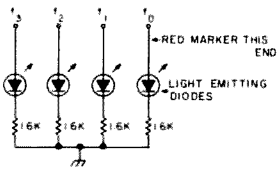
Fig. 4. LED readouts. LEDs are Poly Paks 92CU1790 low current LED MV-55.



layout is shown in Fig. 2.

The user may etch his own PC board or may use perforated board if he wishes; however, a universal breadboard such as a Continental Specialties QT-59S ($12.50) or AP Products 923261 Terminal Strip ($12.50) will make things a lot easier. With the universal breadboard, no soldering is required, as all connections are made with #22 AWG solid hookup wire. The breadboard is recommended to facilitate circuit changes and additions to the experiments.

Some type of indicator is needed to display the outputs of the ALU. A 20,000 Ohms/volt voltmeter (which will read 0-5 volts), a dc oscilloscope, or a series of light emitting diodes may be used. The circuit in Fig. 4 shows 4 LEDs connected to the ALU to indicate HIGH (1 bit) and LOW (0 bit). The LEDs used are type MV-55, available from Poly Paks (5 for $1.00, part number 92CU1790).

The Experimental Setup

The basic experimental setup is shown in Figs. 4 and 5. The instruction lines are brought out to the left, the data inputs are brought out to the right, and the outputs are brought out to the bottom, or lower left. The input, output, and instruction connections may be made to terminal strips, vacant connections on the breadboard, or to other suitable terminations. Pin 24 is connected to plus 5 V from the power supply, and pin 12 is connected to the power supply ground.

The outputs from the 74181 will either be HIGH (H) or LOW (L) voltage levels. A HIGH will be 2.4 volts minimum, but not greater than 5 V. A LOW will be .4 V or less. A 20,000 Ω/V voltmeter may be used to read the output levels, or LEDs may be connected as shown in Fig. 4. If the LEDs are used, a lighted LED will be a HIGH and a non-lighted LED will be a LOW. In these experiments, a "0 bit" is represented by a LOW while a "1 bit" is represented by a HIGH.

Ground Rules and General Notes

1. The 74181 will operate over a range of 4.75 V to 5.25 V. Operating with voltages outside this range may produce results which are not defined. Operating with a voltage greater than 7 V (the absolute maximum rating) may damage the chip.

2. Don't short the outputs to ground. If more than one output in a HIGH state is shorted at one time, the chip may be damaged.

3. A previous article, "Two Finger Arithmetic,"[1] should be read thoroughly and kept handy as a reference when performing the experiments described.

EXPERIMENTS

Data Transfers

Connect the ALU as shown in Fig. 6. Note that 6 connections form the "instruction word" and are used to select the function of the ALU chip. As connected, this "instruction" will permit data to pass directly from the "A input" to the "output" without changing. The data appearing at the A input is a 0110 and is transferred directly to the output, without change, as a 0110.

The data transfer is a useful instruction within a computer, as it permits data to be transferred from one memory location to another memory location without being changed. Thus, data may be duplicated or placed in a more convenient memory location.

Clear or Set to Zero

Fig. 7 shows the instruc-

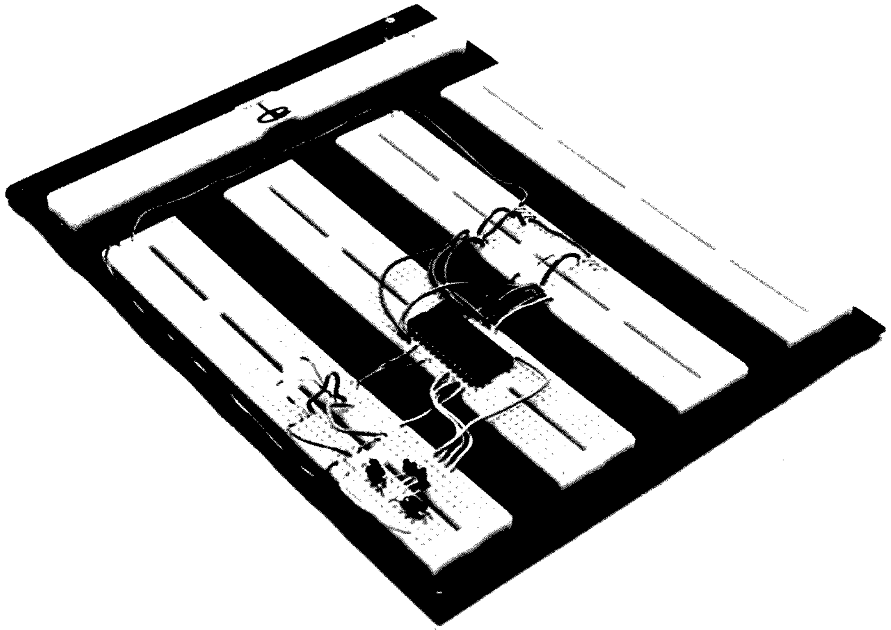


Fig. 5.

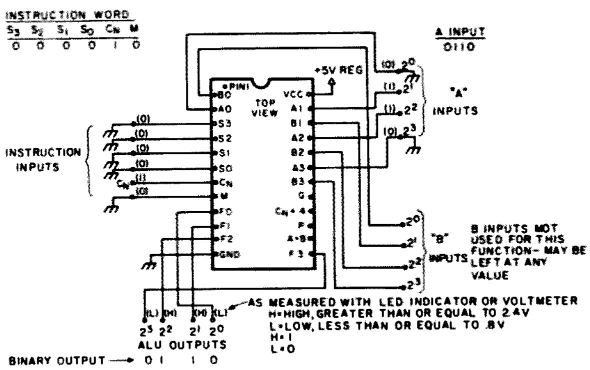

Fig. 6. Data transfer. Output = input from A.

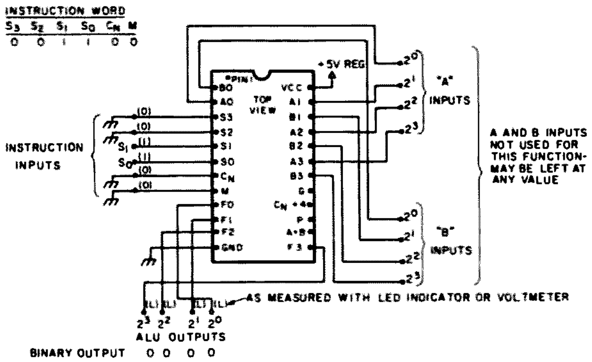

Fig. 7. Clear or set output to zero.

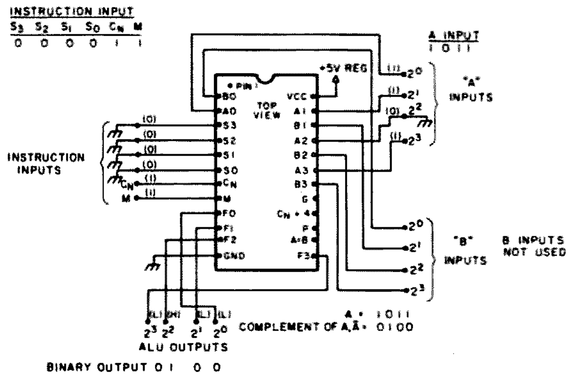

Fig. 8. Ones complement of A.

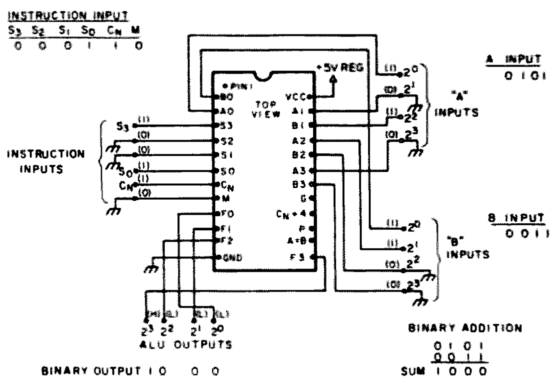

Fig. 9. Binary addition. Output = A plus B.

tion word (or instruction inputs) required for a clear or set to zero. This instruction sets the output to zero, regardless of the data appearing at either input.

This instruction is useful for setting the initial value of a storage location to zero for counting or other purposes. When counting within a computer, a programmer may add "one" to the contents of a memory location every time a given event occurs. To insure a correct count, the contents are set to zero or "initialized to zero" before the count starts.

Complement

The complement of a number can be obtained by using the instruction word as shown in Fig. 8. The data input is 1011 and the output is 0100, which is the complement of the input.

Addition

Addition is performed by using the experimental setup as shown in Fig. 9. The output will be the sum of the data on the A and B inputs. Thus, as shown,

$$\begin{array}{rl} 0101 & (5_{10}) \\ +\,0011 & (3_{10}) \\ \hline 1000 & (8_{10}) \end{array}$$

Similarly,

$$\begin{array}{rl} 0011 & (3_{10}) \\ +\,1010 & (10_{10}) \\ \hline 1101. & (13_{10}) \end{array}$$

But now add A and B as follows:

$$\begin{array}{rl} A = 0111 & (7_{10}) \\ B = 1011 & (11_{10}) \\ \hline 1\;\;0010 & (18_{10}) \end{array}$$

carry bit

The ALU has only 4 data outputs; thus, the results will appear as 0010. This simple arithmetic operation has exceeded the capability of the ALU. We call this an "overflow" condition and say that "overflow" has occurred and that a "carry" has been generated.

Overflow is the phenomenon that separates binary arithmetic from computer arithmetic. When performing binary arithmetic on paper with a pencil, number size limitations are of little concern (you can always add another sheet of paper). When doing arithmetic with computer elements, number size is a serious concern since there is a hardware limit to the size of the "arithmetic word." In these experiments, the "arithmetic word" size is 4 bits. If we connected two ALUs together, we would have an 8 bit "arithmetic word." With an 8 bit arithmetic word, overflow would not occur and a carry bit would not be generated until a sum exceeding 8 bits was generated.

If overflow were to occur without the user being aware of its occurrence, erroneous results could occur. For this reason, it is important to have the capability to detect the occurrence of overflow. Overflow can be detected on the 74181 chip by monitoring the output of pin 16, the inverted carry output. This output is normally used to feed a "carry" input on another 74181, but it may also be used to detect the occurrence of a carry bit (overflow). This output is inverted, so it would normally read HIGH with no carry and LOW if a carry occurred. An LED may be connected to the carry output as shown in Fig. 10, so that the LED will light if a carry or overflow is present.

By connecting the addi-

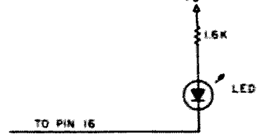

Fig. 10. LED connected to carry out.

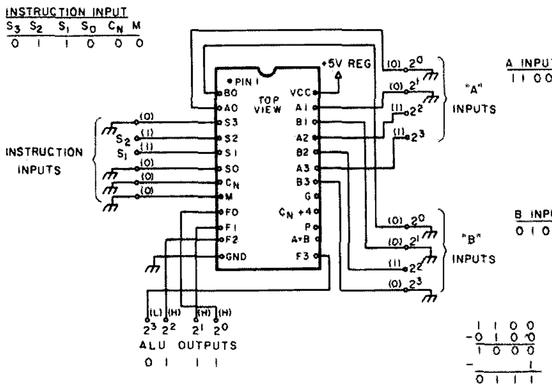

Fig. 11. Subtraction: A minus B.

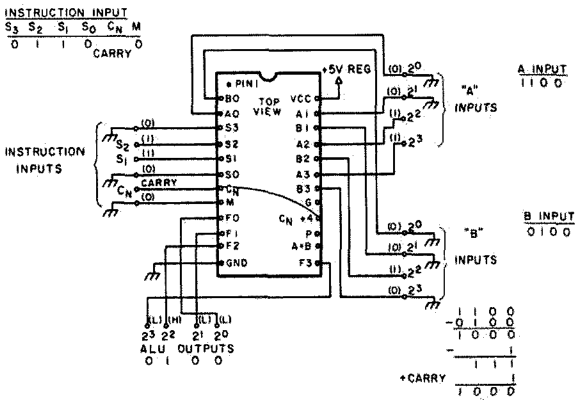

Fig. 12. Subtraction: A minus B, plus carry.

tional LED as shown in Fig. 10, we have gained an additional bit for arithmetic. We have a 4 bit arithmetic word, but we are able to display a five bit result.

For example:

```
  1 1 1 1   (A input)
+ 1 1 1 1   (B input)
1 1 1 1 0
↑
(the fifth bit, the LED for
carry, will be lit)
```

Subtraction

Subtraction using twos complement arithmetic is done by using the instruction shown in Fig. 11. This experiment shows an example of A-B. The 74181 performs the following functions in order to effect a subtraction:

1. The twos complement of the B input is obtained by complementing the value and adding 1. The addition of the "1" is a result of making the *inverted* carry in (C_N) a LOW.

2. The twos complement of the B input is added to the A input. For example, let us subtract 4_{10} from 12_{10}. The answer, of course, should be 8_{10}.

```
A = 12₁₀ = 1100 ──────────────→ 1100
B =  4₁₀ = 0100 ── 2s comp. ──→ + 1100
                               1 1000 = 8₁₀
```

The result as displayed on the 4 output bits would be 1000 8_{10}. A=12, B=4, and A-B=8. Carry would occur and the carry LED would be lit, but in this case discarded, because it has no significance.

Do the following problem: 3 - 4 = ? Let A = 3, B = 4. What are the results?

```
                     internal operation
A = 3 = 0011 ─────────────────→ 0011
B = 4 = 0100 ── 2s comp. ──→ +1100
                              1111 = negative 1
```

The result is negative 1 (or minus 1), which is the correct answer for 3 - 4.

It may appear that there is no way of knowing whether a result is negative or positive; however, this is not the case.

Consider the number 1 in binary. On paper, we may write the number one as 1, as 01, or even 0000001 if we wish. To get a negative one, we take the twos complement, which in the case of 0000001 is 1111111. This representation of a negative number is not completely correct, since the "1" really has an infinite number of zeros in front of it. To be correct, 0000001 is really "(infinite number of zeros) 0000001," and the complement is "(infinite number of ones) 1111111."

It can be shown that, in a negative number, the leftmost bit at infinity is a 1 bit. Of course in the real world we can't go on writing down an infinite number of 1 bits to get to the leftmost bit, but we can define the leftmost bit in our arithmetic word as the "sign bit." Using this definition, the leftmost bit of our four bit arithmetic word is now the sign bit, and in our example the number 1111 becomes a negative number.

Note that, by adopting the leftmost bit in our four bit arithmetic word, our arithmetic is now restricted to 3 bits. The largest positive number that we can generate is 0111=7_{10}. The largest negative number that we can generate is 1000=8_{10}.

Multiply by 2

The instruction shown in Fig. 13 is designated an "A plus A" instruction, and has the effect of multiplying A by 2. This instruction may also be called a "shift left by 1 bit" instruction, since it shifts the number A to the left by one bit.

This instruction is useful for generating the squares of numbers and may be used as a part of a program to perform multiplication.

Conclusion

ALUs, such as the 74181 described in this article, are practical building blocks for the computer designer and do exist as important parts of computers available on the market today. These ALUs may stand alone as independent units, or they may be combined with other functions to form a device such as a microprocessor. Thus, the concepts described are applicable to large scale computers, independent ALUs and microprocessors. ■

Satellite Orbit Predicting

--using a pocket calculator

How would you like to be able to press one button and get complete satellite orbit information without referring to various tables and graphs? Now that the new programmable pocket calculators are here, it is entirely feasible to do just that after a simple program entry which will give you all the information on your favorite satellite for the next month or so.

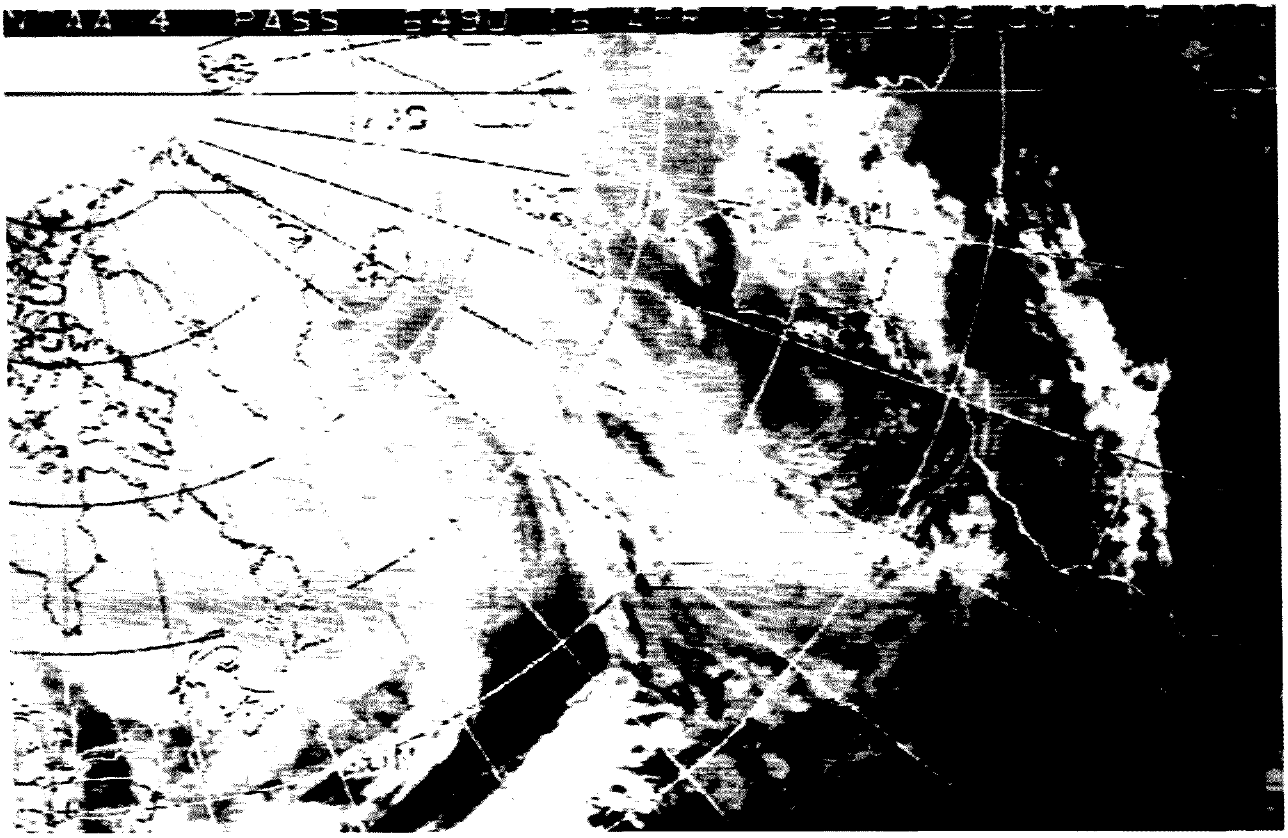
For the past several months I have been following the passes of the NOAA 3 and 4 satellites and recording the pictures coming from these modern day weather-predicting devices. Pictures have been obtained by FAX reproduction as well as oscilloscope display as described in a number of articles published in this magazine.[1]

A computer program has been written for the HP 25 pocket calculator, which is the new programmable calculator made by Hewlett Packard. The calculator is currently selling for around $180, and is an absolutely amazing little device which is fully programmable up to 49 steps. Programming is done in the same way a normal calculation is performed so that it is not necessary to study BASIC or FORTRAN 4 programming in order to program the device. Since there are "GO TO" and conditional steps available on the calculator, it is possible to have conditional branching in the program much the same as available in modern day computers.

In the program shown here it is possible to just punch in the date of the month, such as the number "3" for the third of April, and then by pressing the program "run" button, get the pass number, the equatorial crossing time for that date, and the degrees west that the satellite crosses the equator. What I generally do is assign a number to the first pass of the month, and then by consulting the *73* satellite table or ARRL nightly broadcasts for NOAA 4, get the first pass of the month info for making up[2] the program. It is necessary to know the time of a given pass of the satellite over your area and the degrees west longitude of this particular pass (which we will call pass #1 for reference). Once this info is found and entered into the program, it is only necessary to enter the date of the month and pass number in order to find out the time and equatorial crossing longitude. For example, in the program shown here, if we are interested in finding out the first pass of the day information for April 2, we just press the number two button and hit the run/start. We then see displayed the first orbit number (1), the day (2), and the time in hours (local 7.82). By then pressing the number one (orbit number just found) and the run/start button again, we see displayed the degrees longitude (242.9° W) equatorial crossing for that orbit.

After entering the program into the HP 25, also enter the satellite constants in the program memory shown as the "registers" 0-7. It then becomes obvious that the constants for any of the Oscar or NOAA satellites may be entered to give the desired orbit information.

A word about the register constants here: the first constant, R0, is the number of passes per day, in this case for NOAA 4. R1 is not used except in the program memory and can be ignored. R2 has the value 115, which is the time in minutes that the satellite takes to orbit the earth (in this case NOAA 4). R3 is 1440, the total number of minutes in one day. R4 is the day of the month to which is added the time, in days, of the first orbit. For example, the first orbit decided on is on the second of April, so we would add the number 2 to the time of the first orbit in days (not hours), which turns out to be .3256944 (7.82 hrs or 7:49 am); hence we come up with the number 2.3256944 days for the constant R4.



R5 is the degrees west longitude of the first orbit obtained as described above, and in this case is the number 242.9. R6 is the change in longitude for each pass of the particular satellite chosen and in this case for NOAA 4 is 28.75°. A more accurate number will give a more accurate predict orbit. R7 is 360 which turns out to be the familiar number of degrees in a circle!

As far as changes in the program from month to month, it is possible to be within one quarter of a degree or so after about one month's time, so I change the program about once per month to update the information.

Referring to line "02" in the program body: This particular entry is the only one that has to be changed in the program body if the date of the first orbit is changed when getting new orbit info. In this particular case, the number "2" refers to the day of the month for the first orbit programmed, which is the same number two discussed above in reference to constant R4.

The program here is particularly useful for tabulating a full month's orbits for a particular satellite. Since the passes for each day occur about the same time, it is only necessary to know about the first pass of each day, and the other passes can be found through simple calculation or by substituting the pass number in the second half of the program.

A similar program may also be developed for other programmable calculators such as the TI unit or more sophisticated computers. ■

The Death of Negative (IBM) Logic

--some fundamentals of logic design

During the past ten to fifteen years, conventions in logic design symbols have solidified to the point where one professional designer can finally communicate with a second with a minimum amount of confusion. This was a very painful growth period, but it's finally over. As an amateur logic designer, you have a choice of defining your own symbols and terms or going with the tide and using the industry standards. I strongly suggest you inflate your water wings and push out with the standards. The conventions are not very involved, and using them just takes a little practice. There are holes in some definitions, but by and large the system works.

I would like to make the newcomer's entry as simple as possible by going over the following terms and symbols:

- •Truth Tables
- •Positive/Negative Logic
- •Standard Symbols
- •Equivalent Symbols

I would also like to show how to name a function and why the choice of names is so important. The second section of this article, about positive and negative logic, should be of interest even to the experienced logic designer.

Truth Tables

The simplest version of this handy tool allows you to get a picture of what you want your logic design to do. The table consists of an input side and an output side. The input side contains a column for each of the input lines that you have to deal with; the output contains the results expected for every possible combination of inputs. For example: You need to light a lamp whenever one of your home sensors shows an open door or window or when you push a self-test button. You only want an entrance to light the lamp if the system has been enabled by a local switch.

Your inputs are:

- •Door #1 (D1)
- •Windown # (W1)
- •Self Test Switch (ST)
- •Enable Switch (ES)

Your output would be:

- •The Lamp

The truth table will contain five columns constructed as follows:

ES	ST	W1	D1	Lamp
0	0	0	0	0
0	0	0	1	0
0	0	1	0	0
0	0	1	1	0
0	1	0	0	1
0	1	0	1	1
0	1	1	0	1
0	1	1	1	1
1	0	0	0	0
1	0	0	1	1
1	0	1	0	1
1	0	1	1	1
1	1	0	0	1
1	1	0	1	1
1	1	1	0	1
1	1	1	1	1

The ones and zeros in the input field are simply the

binary progression of four bits. The binary progression makes sure that no combination is left out of the table. The output column is generated by analyzing your requirements for each possible combination of inputs. Tables larger than this can be used. I have a different version for my home grown computer that has 60 outputs with better than 100 inputs, but as you can see, they become large very quickly.

Positive and Negative Logic

Suppose that two logic designers, one on Earth and the other on Mars, are asked to analyze a logic module and to produce a truth table. Each designer is given a voltmeter and an operating module. Both modules are exactly the same and both operate exactly the same.

The first thing the two designers are asked to do is to construct a *voltage* truth table. The modules both look like Fig. 1.

The two *voltage* truth tables are:

Earth

A	B	C
0 V	0 V	0 V
0 V	+5 V	+5 V
+5 V	0 V	+5 V
+5 V	+5 V	+5 V

Mars

A	B	C
0 V	0 V	0 V
0 V	+5 V	±5 V
±5 V	0 V	+5 V
+5 V	+5 V	+5 V

Both tables are exactly the same, and both show that when a +5 V signal is applied to either A or B, the output on C will be +5 V. This appears to be an OR function, right? Not necessarily.

Both designers are then asked to produce a *logic* truth table from the *voltage* truth table shown above. The Earth designer has been taught that the higher voltage is represented by a TRUE shown as a "1" in his logic table. The lower voltage is shown by a FALSE or a "0" in the table.

The Martian designer has been taught just the opposite; that is, a high is a FALSE or "0", and a low is a TRUE or "1".

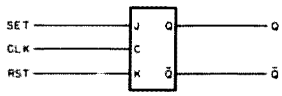
The substitution of 1s for +5 V and 0s for 0 V by the Earthling, and 0s for +5 V and 1s for 0 V by the Martian, produces the following different logic truth tables:

Earth

A	B	C
0	0	0
0	1	1
1	0	1
1	1	1

Mars

A	B	C
1	1	1
1	0	0
0	1	0
0	0	0



K	J	C	Q
0	0	0	0
0	0	1	0
0	1	0	0
0	1	1	1
1	0	0	0
1	0	1	0
1	1	0	0
1	1	1	Toggle

Fig. 9. JK.

The Earthman thinks he has an OR, the Martian thinks he has an AND, but both have the same logic module.

The Earthman is working in what we call POSITIVE logic, the Martian in NEGATIVE logic. If the two were to continue their analysis of all module types available, they would find that AND = OR and NAND = NOR, depending on your point of view.

Negative logic was used widely right here on Earth in many places (IBM for one), but luckily the practice is going away. There may be good reasons to use it in certain cases, but I would think that they would have to be very good reasons to put up with the confusion it causes. So much for the world of negative logic; from now on everything will be referenced positively. The higher of the two logic levels will be a 1 or TRUE, the lower 0 or FALSE.

Standard Symbols

The standard symbols for the most common logic elements are shown in Figs. 2-4. From these the elements in Figs. 5 and 6 were generated.

As you can see, the difference between a NAND and an AND is simply that the output is inverted (as signified by the small circle on the output).

Flip flops are a bit more difficult to describe. This family consists of Set/Reset (R/S), D type. and JK (Figs. 7-9). Most flip flops have several more inputs than those shown; for an exact definition of the operation of each, you should get a Texas Instruments Manual.

Equivalent Gate Symbols

Since it is possible to use a NAND to perform an OR function and a NOR to perform an AND function, logic designers came up with specialized symbols to show when gates were used in this manner. For example, if you have to OR three lines whose active state is low, you would use a three input NAND. The logic could be drawn using a standard NAND symbol, as shown in Fig. 10, but Fig. 11 would more clearly show the ORing function. Exactly the same logic gate is used in either case, but it is now apparent that an ORing is taking place by the shape of the symbol.

The gate symbols shown in Figs. 12-15 are all equivalent. The important thing about these symbols is the use of

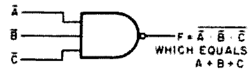


Fig. 10.

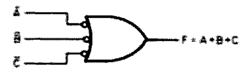

Fig. 11.

Fig. 12. ANDing function using a NAND.

Fig. 13. ORing function using a NOR.

Fig. 14. ORing function using a NAND.

Fig. 15. ANDing function using a NOR.

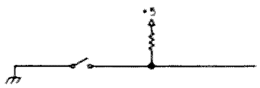

Fig. 16.

the inverter symbol on the input. After you have completed a logic design using these four symbols, if you have anything other than negated inputs connected to negated outputs, you have an error. Either your incoming term is misnamed, or it needs to be inverted. It is quite possible to do all your logic design without resorting to the equivalent symbols, but the result will be less readable.

Term Names

When picking names for the terms in your design, be sure to choose the active function. For example, the circuit shown in Fig. 16 is widely used to generate binary logic levels from a switch. If closing the switch pulls the line to a logic zero and clears the system, it should be named $\overline{\text{CLEAR}}$ (spoken, "CLEAR NOT"), rather than "DON'T CLEAR." Always think of the action to be performed, name it, and *then* add the negation if necessary. Don't attempt to find a name for the true condition first. ■

... And on the Other Side

--binary and octalization of decimals

In a previous effort, I described a simple method of taking a whole number written in base 10 (your ordinary everyday numbering system) and producing its equivalent in binary (or base 2).[1] You could also turn it into its octal equivalent (base 8), if that's what you desired. The beauty of the method was that the entire math depended upon your ability to divide by the number 2 or the number 8.

The logical question is, "What do we do if there is a fractional part to the number?" Putting it another way, "What do we do with numbers to the right of the decimal point?"

Taking a peek in the rearview mirror, the temptation is to ask, "Why bother?" If the rearview mirror shows an interest in computers, the answer is, "Let's bother!" Systems that you and I might hope to afford generally eat binary and octal, so the least we can do is appreciate the "food" shoved down their expensive electrical gizzards.

We know that in the decimal system each digit to the right of the decimal point has a value. The progression is tenths, hundredths, thousandths, and so on. Thus 0.125 is really the sum of one tenth, two hundredths and five thousandths.

With muted thanks to Miss Venables, who taught me all these good things, let's climb out of the sandbox and examine the same idea in the binary system. The values to the right of the decimal point have values of one half, one fourth, one eighth, one sixteenth, and so on. Octal is a bit rougher, as base 8 progresses rapidly. The values are one eighth, one sixty-fourth, one five hundred twelfth, etc.

With these basics in mind, we can skip down the primrose path of conversion from decimal to either octal or binary by extending our grasp on basic math to the extent that we can skillfully multiply by two or by eight as the case may be.

Suppose we consider the delightful decimal 0.53 and wish to convert it to binary. We are really asking the following successive questions: "How many one halves does this number contain? How many quarters? How many eighths? How many sixteenths?" And so it goes, until we get to the final binary equivalent. To convert it to octal we would ask the same questions, but would substitute the octal place values. Rather than go through this, though, we merely start multiplying by two or by eight and look for the signposts that give us the proper numbers to put down in our conversion. For the binary conversion our numbers will be limited to zero and one, while for octal the numbers will range from zero to seven.

The Method

We will assume that we want to take the decimal base ten value 0.53 and convert it to the equivalent binary notation. Please make a firm note that there is a zero to the left of the decimal point. When you start flirting with computerese or definitive math, zero is a powerful animal that can really hang you up when ignored or misused. The method is simplicity itself:

- Multiply 0.53 by 2 ... 1.06.
- Any figure to the left of the decimal point, including zero, becomes our first binary digit in the desired answer ... 0.1.
- We now multiply the decimal portion of the first multiplication again by two (0.06x2) ... 0.12. Thus the next digit in the binary answer is a zero ... 0.10.
- We merely continue this process until we are satisfied that our conversion is relatively complete. In the case of 0.53 (base 10) to binary, carrying this process to seven places would give us an answer in binary of 0.1000011. It is definitely interesting to take the time to see what the absolute value of the binary answer is in order to see how successful the conversion has been. The binary answer is the arithmetic sum of the values of each binary place, i.e., the sum of one half (0.500), plus no fourths, plus no eighths, plus no sixteenths, plus no thirty-seconds, plus one sixty-fourth, plus one one hundred twenty-eighth.

Those numerical specifications look like this:

0.500 (one half)
0.015 (one sixty-fourth)
0.007 (one one hundred twenty-eighth)
———
0.522

Note that in the conversion process there is a slight discrepancy in the third decimal place. If we had taken the conversion of 0.53 base 10 to an additional binary place we would have gotten even closer, which illustrates that eight places is not overkill when converting a decimal base 10 form to binary.

The octal conversion process is identical in methodology but we now use the number 8 as our multiplier. Ergo:

0.53 x 8 = 4.24 . . . 0.4
0.24 x 8 = 1.92 . . . 0.41
0.92 x 8 = 7.36 . . . 0.417
0.36 x 8 = 2.88 . . . 0.4172

Thus the octal conversion held to four steps (for simplicity) is 0.4172.

On a one time basis to understand the point, it is worthwhile to wade through the place values of this conversion to see how close the octal conversion comes to the original decimal (0.53) that we started out with.

0.4172 in base 8 is really the sum of:

4 x 1/8	or	0.5000
1 x 1/64	or	0.0150
7 x 1/512	or	0.0133
2 x 1/4096	or	0.0004
		0.5287

Note that the difference between the binary expansion and the octal expansion is, as mentioned, due to the fact that binary uses only ones or zeros, while octal uses all numbers from zero to seven. Thus, when you examine the binary result to see how close your conversion is, the process is simpler than the octal case where each place value has to be multiplied by the number in the octal answer. It is also interesting to note that the octal conversion in this case was a more accurate conversion in four steps than the binary conversion was in a larger number of steps. If we had taken the binary conversion one more step (for a total of 8), our binary conversion would have gone from 0.522 to 0.525, which is still not quite as good as the octal conversion of 0.5287.

Without quibbling over the merits of binary versus octal final accuracy, you just might now be nourishing the faint suspicion that "the computer" may have some trouble in "exactly" representing some numbers fed into its inner workings. This is an accurate conclusion on your part. Putting it another way, the math through the computer may well not be "on the money" — just damned close. ■

Build the Safari RTTY Terminal

--an active filter modem from Africa

After various experiments with coils and capacitors, it was decided to try active filters for decoding. The main problems in decoding RTTY are the high amount of noise on the signal, the QSB, and a very often found frequency instability of the received RTTY signals. To bring all this under one hat together with the demand of low cost, a lot of compromises had to be made.

Fig. 1 shows the block diagram of the RTTY encoder-decoder.

To become independent of QSB, a limiter had to be placed at the input. A low pass and a high pass filter reduce the noise above and below the wanted frequencies (2125 Hz and 2295 Hz). After these stages common to all frequencies, the filter stage follows. The filtering is done in a somewhat unusual way. The signal (a square wave) is fed through a notch filter designed to eliminate the basic frequency of the square wave.

Having passed this, the square wave looks like the one in Fig. 2.

This signal, together with the square wave as it looked before the notch filter, then enters an op amplifier used as a differential amplifier.

If the input signals to this op amplifier are equal (applies for all frequencies except the notch frequency), there is no output. For the notch frequency there is a sine wave output. This sine wave is rectified and detected in an op amplifier, wired as a Schmitt trigger. In order to observe a received signal, add a pair of LEDs including transistor drivers. The Schmitt trigger is followed by the pre-driver and driver stages for the teleprinter magnet.

The encoder basically consists of an unijunction oscillator. This of course does not generate a square wave and is therefore followed by a "flip flop" which generates a square wave of exactly 50% mark space ratio. Since a flip flop divides by two, the unijunction oscillator has to run at twice the frequency.

To change the frequencies (mark space) a transistor 2N2904 is used to change the value of the charge resistor for the unijunction oscillator. The BC108 in front of the 2N2904 is to change the switching for "upside down" transmission, in the SSB mode. The square wave coming out of the flip flop is fed into the decoder input. A sine wave signal to modulate any SSB or AM transmitter is obtained after the combining amplifier.

The frequency of the notch filter is determined by resistor R and capacitor C and is worked out according to the formula below (see Fig. 3):

$$f = \frac{1}{2\pi RC} \qquad \begin{array}{l} f \text{ in Hertz} \\ R \text{ in Ohms} \\ C \text{ in farads} \end{array}$$

The circuit of the complete encoder-decoder is shown in Fig. 4.

Construction

A print of the PC board is shown in Fig. 5 with wire links shown. The first step is to place the wire link between pins 4 of IC4 and IC5, as this is covered by the IC holders. Assembly from

Reprinted from *Radio ZS*, Volume 29, Number 3, pp. 10-13.

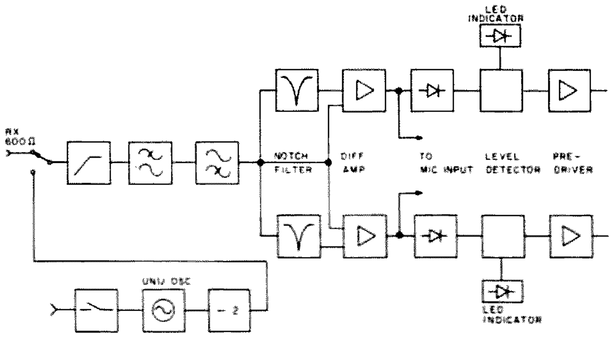

Fig. 1. Block diagram of 170 Hz shift RTTY modem.

Fig. 2. Square wave after having passed through the notch filter.

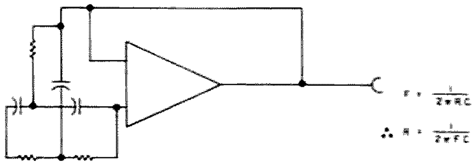

Fig. 3. Basic notch filter.

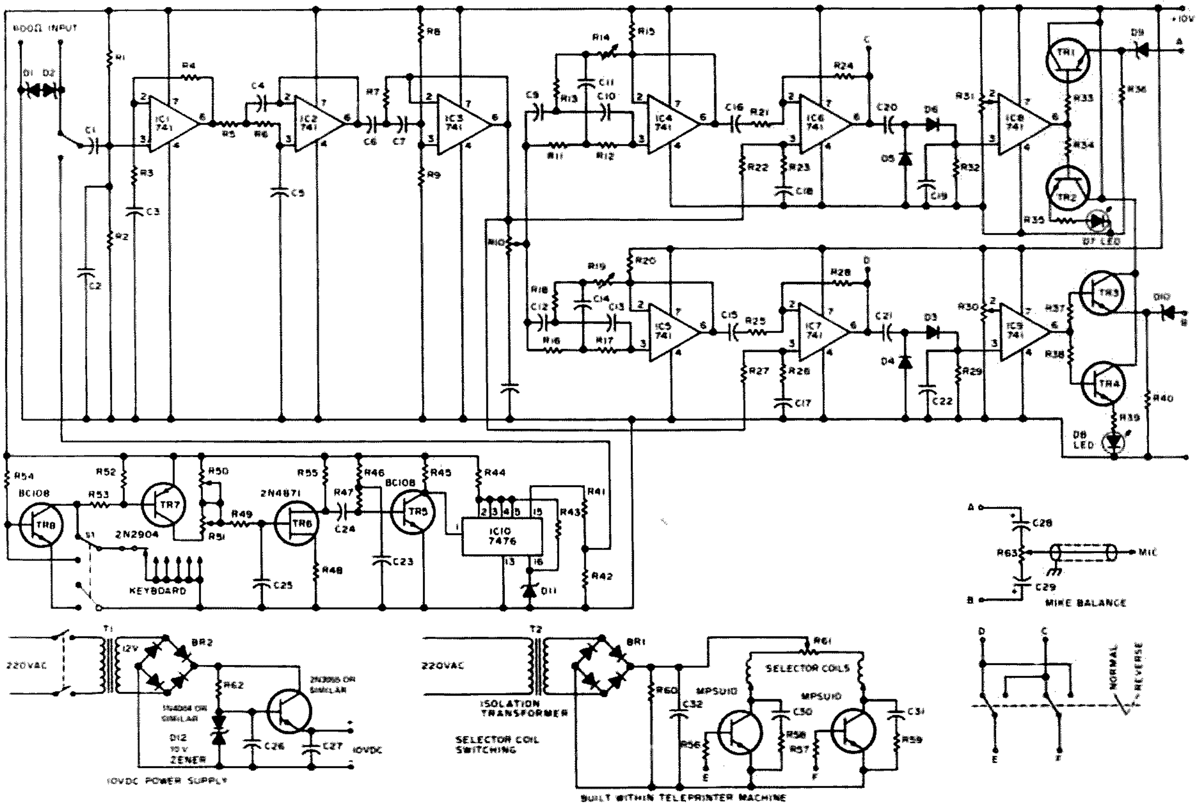

Fig. 4. Encoder-decoder circuit diagram, teleprinter switching, 10 volt supply, and other controls on the terminal unit.

then on is straightforward. After all the components have been installed, check the board but do not plug in the ICs. Connect the unit to +10 V and check that the voltage on pin 16 of IC10 is +5 V. If not, change R44 to achieve this value.

Encoder

With an oscilloscope connected to the collector of TR5, check that the unijunction is triggering. Then insert the IC 7476 into IC10 socket and check for a square wave at the encoder output socket. Connect a counter to this same position and adjust the two 5k trimpots so that, with the two leads which go to the keyer circuit shorted, the output is at 2295 Hz and with them disconnected, the output is at 2125 Hz.

Decoder

Insert IC1, and with audio signal generator connected to the input terminal, check with the oscilloscope on pin 6 that the output is a square wave and remains at the same level for all input voltages. Insert IC2 and IC3; check with an oscilloscope connected to the center of the potentiometer connected to pin 6 of IC3. Tune the audio generator across the band and see that the output increases from below 2125 Hz to above 2295 Hz. Insert IC4, IC5, IC6 and IC7. Connect the scope to pin C of IC6 and see that the output increases sharply at 2125 Hz. This resonant point is governed by the two 8.2k resistors connected to pin 3 of IC4; it may be necessary to pad these resistors to bring the peak exactly onto 2125 Hz, remembering that the lower the resistors, the higher the frequency.

Now do the same at IC7, at point **D**, but for a frequency of 2295 Hz. Remove the audio generator. Insert

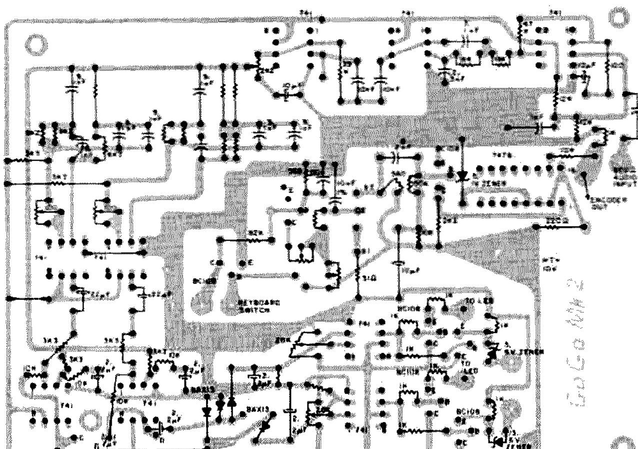

*Fig. 5. Encoder-decoder PC board and component layout. *Jumper emitter of TR7 to positive rail.*

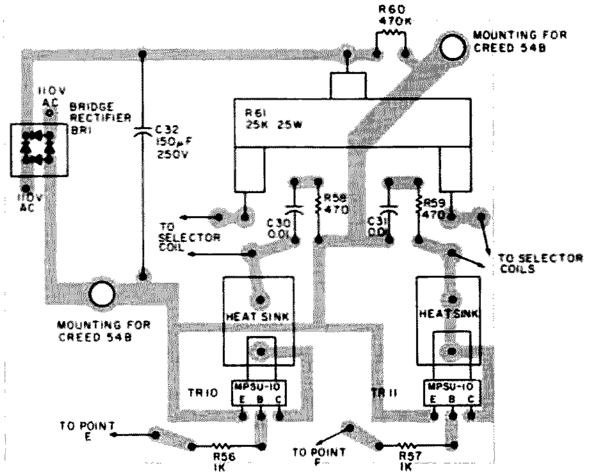

Fig. 6. Teleprinter switching PC board and component layout.

IC8, adjust the 20k potentiometer R31 connected to pin 2 of IC8 until the LED lights up, then back off the potentiometer slightly. Reconnect the audio generator and check that the LED lights up to 2125 Hz ± 45 Hz.

Repeat the above for IC9 and a frequency of 2295 Hz. If the bandwidth at the resonant frequency is too broad, adjust the R14 and R19, on IC4 and IC5, to narrow the bandwidth. These are normally set at about 5 Ohms. Be careful that the setting does not result in ringing in the notch filter.

Place a voltmeter between each output and earth and check that the voltages rise to +3.8 volts whenever the audio generator is on the correct frequency.

Now connect the output of the encoder, when it is switched to 2125 Hz, to the input of the decoder. Connect the oscilloscope to point C and adjust R12 so that the output is a sine wave. Switch the encoder to 2295 Hz and likewise check the output at point D. Now connect the oscilloscope to the mike input lead, and with the balance potentiometer, adjust both outputs to be the same while switching the encoder between 2125 and 2295 Hz.

The parts layout for the encoder-decoder is shown in Fig. 5 and the parts layout for the teleprinter switching is shown in Fig. 6.

The teleprinter layout shown in Fig. 7 was designed to fit into a Creed 54B teleprinter, but may fit into your teleprinter. The reason a separate board was used was to keep the 150 volt dc line well away from the main modem unit. It is advisable to use an isolation transformer if the unit is operated on 110 volts ac. ■

Never Underestimate the NAND

--introducing the 7400 quad NAND gate

Robert Henson WBØJHS
1016 Polk Blvd.
Des Moines IA 50311

Even a ham who considers himself somewhat knowledgeable on digital logic can be confused when he glances at a new logic circuit for the first time. Though the logic elements involved in any particular circuit are seemingly simple to understand, their interconnection with other elements and devices often tends to make the circuit as a whole confusing to the point of incomprehensibility, especially to the inexperienced. Circuit analysis is also further complicated when logic devices are utilized to perform functions other than that for which they were primarily intended. Unfortunately, these sources of confusion often appear formidable enough to discourage some of the less experienced hobbyists from experimenting with digital logic circuits.

This article will attempt to dispel some of the mystery about the many uses of one of the most basic logic elements, the two-input NAND gate. In addition to explaining its primary function, it will be shown how it may be connected to perform the functions of an inverter, a set-reset flip flop, a switch debouncer, a pulse shaper, a square wave oscillator and even a crystal oscillator. In spite of the rather ominous forewarning that this article is about a *digital logic* element in an *integrated circuit* package, it will be shown that these applications are extremely simple, making this the ideal device for learning the basics about logic circuits.

Basics

For two important reasons, the NAND gates described in this article will all be of the TTL (transistor-transistor logic) family. First of all, TTL is by far the most commonly used logic in current ham projects. Second, it is the least expensive and the most readily available from surplus dealers. The current price of

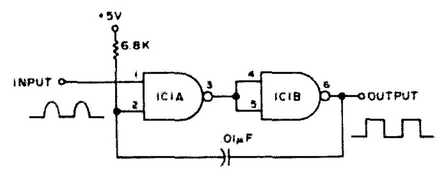

Fig. 3. An input conditioning circuit utilizing two sections of the quad two-input NAND gate.

the 7400 quad two-input NAND gate is a whopping sixteen cents.

Fig. 1(a) shows the common schematic representation of the two-input NAND gate. Fig. 1(b) is the truth table that shows the output of the NAND gate for all possible combinations of inputs. The truth table is the key to understanding the NAND gate, and will be referred to repeatedly in subsequent discussions and applications of this device.

For TTL logic, each "0" in the truth table represents a voltage of 0.8 volts or less. Each "1" represents a voltage of greater than 2.0 volts but less than the NAND gate supply voltage of 5.0 volts.

Fig. 1(c) shows the pin diagram for the SN7400 quad two-input NAND gate. As the word quad implies, there are four two-input gates contained in one dual in-line packaged IC. As was previously mentioned, a regulated five volt power supply is necessary to power the IC. Positive is connected to pin 14. Negative is connected to pin 7.

Internal Circuitry

At this point let's digress for just a moment and take a peek into the innards of the IC. If transistor circuitry isn't your bag, simply skip this section of the article. The following discussion of the internal circuitry is not essential in applying the device, but is presented for those who desire further insight into how the gate actually works. For those who are indifferent about this aspect of the IC, the NAND gate can be treated as a "black box" device.

Fig. 2 shows the transistor circuitry that actually comprises each section of the SN7400 two-input NAND gate. The inputs are actually the two emitter leads of Q1, a double emitter transistor. The output is connected to the collector of Q4.

First, let's consider the case where both inputs are tied to a "1", or a voltage of between 2.0 and 5.0 volts. This will correspond to the bottom line of the truth table listed in Fig. 1(b). The base-collector junction of Q1 will be forward biased for this particular set of inputs, allowing I_{BC1} to flow. This current will be of sufficient magnitude to saturate transistor Q2. The resulting collector current of Q2 will produce a voltage drop across the 1.6k Ohm collector resistor of sufficient magnitude to cause the collector voltage of Q2 to decrease to the point where transistor Q3 is cut off, or effectively open circuited. The rise in potential at the base of transistor Q4 caused by Q2's increased emitter current across the 1k Ohm emitter resistor will be sufficient to saturate Q4, causing its collector voltage to drop to near ground potential, or a logic "0". This is exactly as stated by the truth table of Fig. 1(b).

Now suppose that input A is tied to ground or to a voltage source of 0.8 volts or less. This would correspond to the second line of the truth table of Fig. 1(b). Now a current I_{BE1} will flow from the emitter of Q1 to the grounded input A. In this case, I_{BC1} will be zero, causing Q2 to be cut off or effectively open circuited. No current will flow in either the emitter or collector circuit of Q2. Therefore, Q4 will not be biased on as in the previous case, and will in effect be cut off, causing its collector-emitter junction to appear to be open circuited. On the other hand, the collector of Q2 will be approximately at the potential of V_{CC}. This will cause transistor Q3 to saturate, presenting a logic "1" voltage at the output terminal that is equal to the supply voltage, V_{CC}, minus the voltage drop across the base-emitter junction of Q3 and the diode, D3. This output voltage is typically about 3.3 volts.

Note that the conditions described in the preceding paragraph apply to the cases where either or both input terminals are connected to a logic "0" as previously defined. This corresponds to the top three lines of the truth table.

Diodes D1 and D2 are included to help protect the gate should the inputs be accidentally connected to a negative voltage.

One important TTL design rule should be evident at this point. An open circuited input of a TTL gate corresponds to a logic "1" input rather than a "0" input. Or in other words, to input a logic "0" you must tie the input to ground or to a voltage of less than 0.8 volts so that transistor Q1's base-emitter junction will conduct. To input a logic "1" you may either tie the input to a voltage of greater than 2.0 volts or simply leave that input open circuited.

Gating

Now that we've taken a look at what's inside the NAND gate, let's discuss some of its many uses. First of all, as its name implies, the NAND gate's primary function is that of gating. In a logic circuit, the NAND gate will provide a unique output response of logic "0" if, and only if, both inputs are simultaneously at a logic "1". A perusal of any of the recent issues of *73 Magazine* will uncover digital logic circuits using the NAND gate in this fashion.

Inverter

An inverter is a logic element that provides a "1" output for a "0" input and a "0" output for a "1" input. The two-input NAND gate can be easily converted to perform the functions of an inverter by simply tying the two inputs together. Now, only the top and bottom lines of the truth table apply. The output will always be the inverse of the input.

Like the gating function, the use of the NAND gate as an inverter is very common. The easiest way to gain further insight into the reasons for its use in this fashion is to study current digital logic projects in the ham magazines.

Pulse Shaper

A fast switching waveform is necessary to reliably trigger

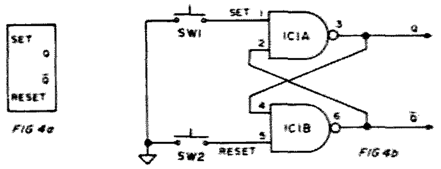

Fig. 4. In (a) is the common schematic for the set-reset flip flop; (b) shows how two sections of the SN7400 can be connected to form a set-reset flip flop.

Fig. 5. Switch "bounce."

TTL flip flops and counters. Slower switching waveforms such as low frequency sine waves will often result in erratic operation. The circuit of Fig. 3 shows how two sections of a 7400 NAND gate can be connected to form a waveform conditioning circuit, providing a TTL compatible square wave output from a slower switching waveform presented at the input.

As was discussed in the section on internal circuitry, the NAND gates are saturated logic elements. In other words, the output is either "on" (at a voltage of approximately 3.3 volts) or "off" (at a voltage of approximately 0.4 volts). The circuitry tends to avoid any in-between output states.

This characteristic is utilized in the circuit of Fig. 3. As the waveform at the input slowly changes from a "0" to a "1" logic level, and vice versa, the abrupt switching characteristic of the NAND gates transforms this input waveform to a square wave output at terminal 6. The inclusion of the .01 uF capacitor from pin 6 of section IC1B to pin 2 of section IC1A provides a transient feedback that further enhances the switching speed of the trailing edge of each pulse.

The circuit of Fig. 3 is often found in digital circuits that contain transistor or unijunction transistor oscillators that do not have TTL compatible outputs. The circuit is also often used to condition 60 Hz half-wave rectified sine waves for use in digital clock circuits.

Set-Reset Flip Flop

A set-reset flip flop is a logic element with two outputs commonly labelled Q and $\bar{Q}$. $\bar{Q}$ is said to be the inverse of Q, since $\bar{Q}$ is always a "1" when Q is a "0", and always a "0" when Q is a "1". A logic "0" applied to the set input of the set-reset flip flop will cause the $\bar{Q}$ output to go to a logic "1" and the $\bar{Q}$ output to go to a logic "0". The flip flop will then remain in this state when the "0" at the set input is removed. In this respect, the flip flop may be thought of as a memory device. A "0" applied to the reset input will cause $\bar{Q}$ to switch back to a logic "1", and Q to switch back to a logic "0".

Fig. 4 shows the common logic symbol for a set-reset flip flop, and how NAND gates can be connected to form this device. In this diagram, both SW1 and SW2 are normally open switches or contacts. If SW1 is momentarily closed, grounding pin 1 of IC1A, pin 3 will switch to a logic "1" as dictated by the truth table of Fig. 1(b). This logic "1" is then present at pin 4 of IC1B. Since pin 5 of IC1B is open circuited and therefore also at a logic "1" level, the output of IC1B switches to a logic "0". Now, when SW1 returns to its normally open position, pin 1 of IC1A returns to a logic "1" voltage. However, pin 2, being connected to pin 6 of IC1B, remains at a logic "0". Therefore the output of IC1A remains at a logic "1" state and the output of IC1B remains at a logic "0" state. This is the "set" condition of the flip flop.

Now, if SW2 is momentarily closed, a "0" is applied to pin 5 of IC1B, changing its output to a logic "1". Both inputs of IC1A are then at a logic "1" causing its output to switch to a logic "0". As before, both IC1A and IC1B retain these output states when SW2 returns to its normally open position. This is the "reset" condition of the flip flop.

Even though there are TTL ICs specifically designed as flip flops, it is not at all uncommon to see the 7400 quad NAND gate being used to implement the set-reset flip flop function. In many cases one half of the 7400 IC will be used as a flip flop while the other two NAND gates will be used as gates, inverters, pulse shapers, etc.

Switch Debouncer

We have already taken a look at one of the peculiarities of interfacing TTL logic with the outside world, namely the requirement of waveform conditioning. Another interfacing difficulty is depicted in Fig. 5. Mechanical inputs such as switch and relay contacts are relatively "noisy." As shown in the illustration, when a mechanical switch or relay contact closes, the contact actually bounces many times before coming to rest in the closed position. These bounces are very fast, being only fractions of a microsecond in duration, and therefore do not affect electromechanical or slower speed electronic circuits. However, to the high speed TTL logic, these contact bounces are a bona fide string of individual input pulses and can cause erratic or unreliable circuit operation. For instance, suppose that a counter circuit comprised of TTL logic elements was constructed to count the number of times the switch contact in Fig. 5 was closed. As can be seen from the waveform produced by this noisy switch contact, the counter would actually count the several contact closures that result as the contact bounces or "chatters" before coming to rest in the closed position. Obviously some sort of interface is necessary to prevent this type of misoperation.

The circuit of Fig. 6 shows how two NAND gates can be connected to form a bounceless switch or interfacing circuit. SW1 can be any SPDT switch or relay contact. As can easily be seen by comparison to Fig. 4, the bounceless switch is no more than a set-reset flip flop. Due to the memory action of the flip flop the circuit will always switch on the initial contact closure and will therefore be immune to the subsequent contact bounces. As can be seen from the illustration, the NAND gates will provide one clean pulse for each contact closure cycle even though contact bounce actually occurs at both the normally open and normally closed switching positions.

Square Wave Oscillators

The NAND gate can also be connected as a square wave generator as shown in Fig. 7. The particular component values of R_t and C_t shown in this diagram will allow oscillation in the 1 kHz range. To explain the operation of this astable multivibrator circuit, let's first assume that we are starting at the instant that pin 6 of IC1B has switched to a logic "0". Since pin 3 of IC1A is at a logic "1" at this same instant, C_t will begin charging through resistor R_t. When the capacitor has charged to a voltage sufficient

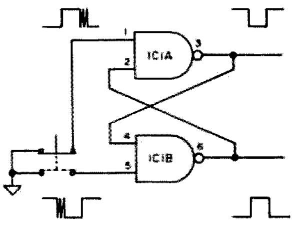

Fig. 6. Two sections of the SN7400 connected to form a bounceless switch.

to provide a logic "1" at pins 1 and 2 of IC1A, the two NAND gates abruptly switch logic output states. Then the logic "1" at pin 6 of IC1B and the "0" at pin 3 of IC1A cause C_t to begin discharging through R_t. When C_t has discharged to a "0" logic level, the gates abruptly change states again. Thus the oscillations continue at a rate dependent on the RC time constant of R_t and C_t.

Provisions for keying the oscillator can be made by disconnecting pin 1 from pin 2 of IC1A. Now, grounding or application of a "0" at pin 1 of IC1A will prevent oscillation, since according to the truth table the output of IC1A must always remain at a "1" as long as one input is at a "0". A logic "1" or an open circuit at pin 1 would allow the oscillator to run.

Two other connections of NAND gates to form square wave oscillators are shown in Fig. 8. Like the oscillator just described, these oscillators also rely on the charge-discharge cycle of capacitors to provide oscillation. In all these oscillators the frequency ranges may be varied by the selection of the RC components. The higher the RC product, the lower the frequency range that will result.

Oscillators of the type shown in Figs. 7 and 8 are often found in circuits that require a TTL compatible clock. Though these oscillator circuits are reliable, some frequency drift can be expected in normal operation.

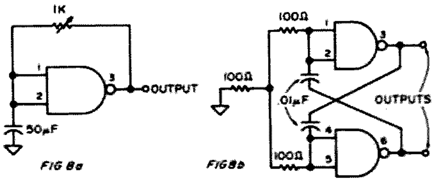

Fig. 8. Two more square wave generators. The oscillator of Fig. 8(a) will oscillate at approximately 45 Hz. The oscillator of (b) will have a frequency of about 50 kHz. See text for description of how frequency may be varied.

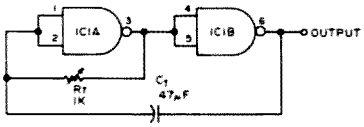

Fig. 7. Two sections of the SN7400 connected to form a square wave oscillator. See text for description of circuit operation.

Crystal Oscillator

Finally, as shown in Fig. 9, the NAND gate can be used to make a crystal oscillator for applications that require a more stable clock pulse than that yielded by the previously described square wave oscillators. As can be seen by comparison with Fig. 8(b), the crystal oscillator is basically the same as the square wave oscillator except for the replacement of one capacitor with a quartz crystal. The upper frequency range of the NAND gate as used in this application is typically 15 MHz though some gates will oscillate at somewhat higher frequencies. The addition of a trimming capacitor in the circuit of Fig. 9(b) will allow for netting the oscillator frequency if this is deemed necessary in certain applications.

Conclusion

The list of applications of the 7400 quad NAND gate presented in this article is by no means complete. Like all other devices, its possible applications are limited only by the ingenuity of the circuit designer. The basic simplicity of the device itself, its low price tag, and its versatility make it the ideal device from which the digital logic neophyte can gain valuable insight into digital logic circuitry. ■

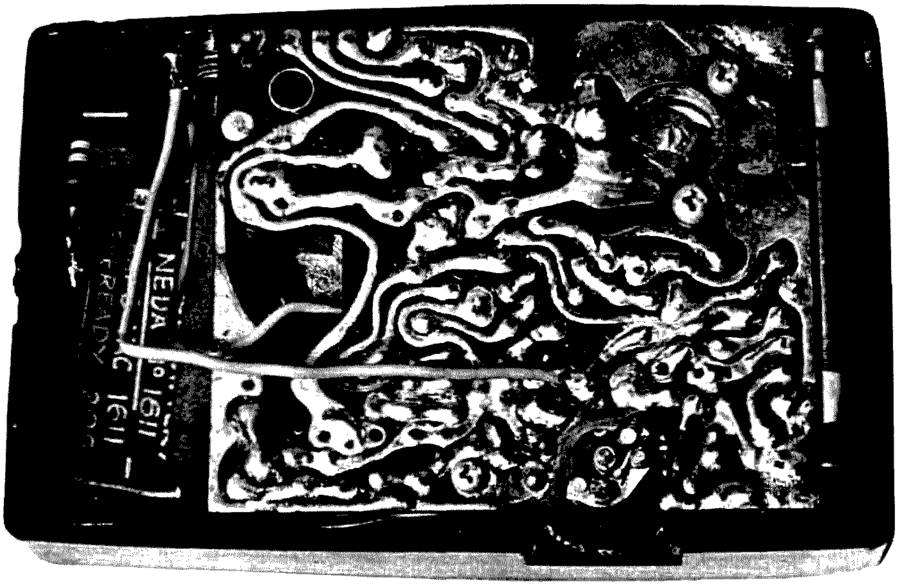
EL Cheapo Signal Tracer

--test gear for the cheapskate

Every ham needs a cheap signal tracer and audio amplifier at some time or another. I discovered my need for one on the day that I connected 117 V ac to the audio output jack of my six meter receiver. (Please don't write and ask how I did this — there are painful memories involved.) When the smoke cleared, the two audio output transistors and their transformer were in such a mess that they were eligible for foreign aid (it's a Japanese receiver). I wanted to get back on the air fast, so I rummaged through the junk box until I found a cheap transistor radio. With this, a resistor, and a capacitor, and ten minutes of work, we were back in business. Best of all, the transistor radio is still usable instantly if I ever fix the six meter receiver.

The modification to the pocket radio involves four steps. First, find the earphone jack and the earpiece and



This photo shows the dropping resistor connected to the positive battery terminal, and the lead from the volume control to the external jack.

Photos by Mike Likavec WA8NNX

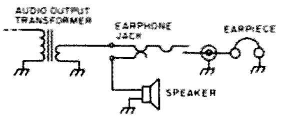


Fig. 1. The original circuit.

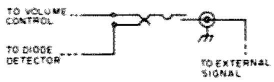

Fig. 2. The modified circuit.

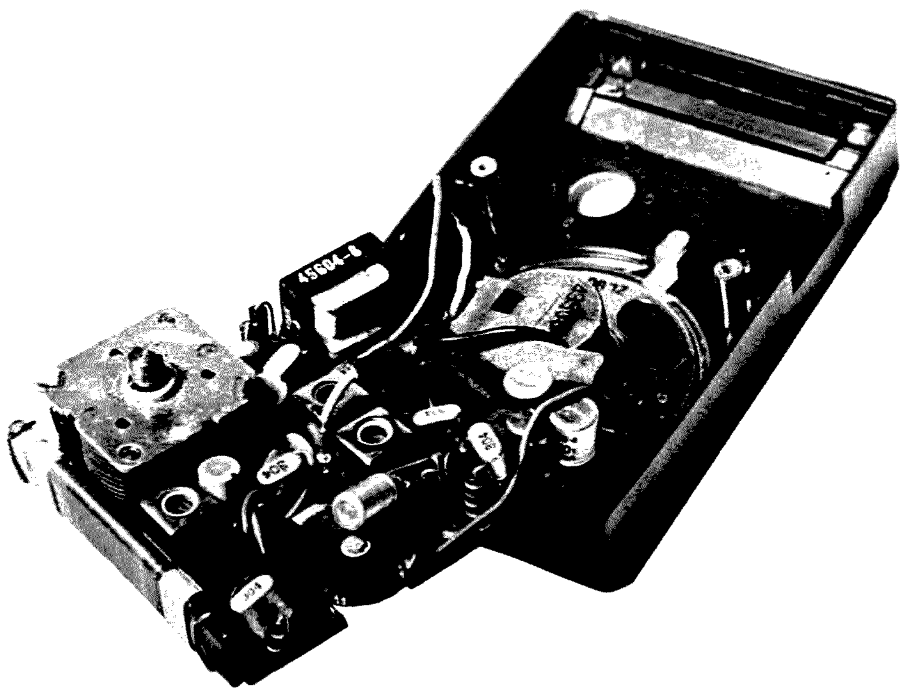

This photo shows the diode detector (nestled snugly between two i-f cans) and its lead (going to the jack).

cord that plug into it. Inside, the jack will have three wires connected to it: a ground, a lead to the speaker, and another one trailing off to the innards of the radio somewhere. This last wire actually goes to the secondary winding of the audio output transformer (see Fig. 1).

Leave the ground wire undisturbed. Unsolder the wire to the speaker and the one to the innards, both at the jack, and note which went where. Solder the ends of these two together and tape them. Now the radio is permanently connected to its built-in speaker.

The second step involves finding the point where the diode detector connects to the volume control. This can be found by tracing back from the center pin of the volume control along the foil until you find the glass diode. Unsolder the end of this diode which goes to the volume control, but leave the other end connected. Solder a piece of insulated hookup wire to the free end of the diode. The other end of this wire is soldered to the pin on the earphone jack that was formerly connected to the speaker. Solder another piece of insulated wire to the point on the circuit board where the free end of the diode used to be. The other end of this wire is connected to the remaining pin on the earphone jack that used to be connected to the innards. Now, without a plug in the earphone jack, the pocket radio will play normally, since the diode detector is connected to the volume control once again, although now through the contacts of the earphone jack (see Fig. 2).

For the third step, cut the earpiece off the end of its cord. Strip the ends of the wires, and with an ohmmeter or continuity checker, find out which of the wires goes to the inner pin of the jack, and mark it. The other lead is the ground connection, which can be connected to an alligator clip. Solder one lead of a 1 uF capacitor to the "hot" lead. This capacitor will keep stray dc voltages out of your pocket radio, thus preventing premature trauma. The free end of the capacitor is the probe tip, and is to be connected to the equipment under test, wherever you suspect audio should be. With the earphone plug inserted in the jack, and the probe connected to the circuit under test, you should now hear the desired signal, rather than Olivia Newton-John. The lead with the capacitor can be built into the plastic end of a discarded ballpoint pen, to make a neater probe tip. The voltage rating of this capacitor must be higher than any voltage you have in the equipment under test. For tube type receivers, 600 volts is usually adequate, while a 50 volt capacitor is adequate for transistor receivers and hi-fi gear.

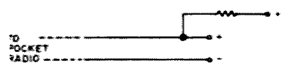

Fig. 3. Battery terminals with added dropping resistor.

If you're going to run the pocket radio from its own battery, this step may be omitted. If you would like to run the pocket radio from the voltage in the gear under test, this formula can be used to find the right value of dropping resistor:

$$\text{Resistance} = \frac{(\text{Available Voltage}) - (\text{Voltage Needed})}{\text{Receiver Current}}$$

For example, if your pocket radio needs 9 V to operate, and 12 V is available, and the pocket radio draws an average of about .010 A, then by plugging the numbers in:

$$\frac{12\text{-}9}{.01} = \frac{3}{.01} =$$

300Ω resistance needed

The wattage needed for the resistor can be figured by the formula $I^2R = P$; that is, the current multiplied by itself, times the resistance, gives the needed power rating in Watts. In the example above, it would be (.01) x (.01) x 300 = .03 Watts. A ¼ Watt resistor would give a more than adequate safety margin. If you're planning to use a 150 V supply to run the pocket radio, a 14.1 kΩ at 1.4 Watts is the calculated value, and 15 kΩ at 5 Watts is adequate and a practical common value. This resistor is connected between the positive terminal of the battery holder and the supply voltage point, as shown in Fig. 3 and the photo.

Once completed, the pocket radio can be used normally, and, by just plugging in the earphone plug/test probe, it becomes a signal tracer or audio amplifier. Total cost is less than fifty cents as promised, and you've still got your radio. ■

FSK with the SB-401

- - simple way to get on RTTY

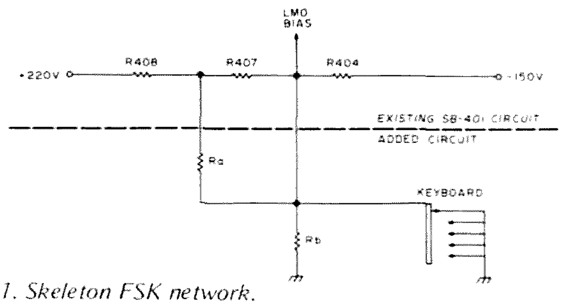

Fig. 1. Skeleton FSK network.

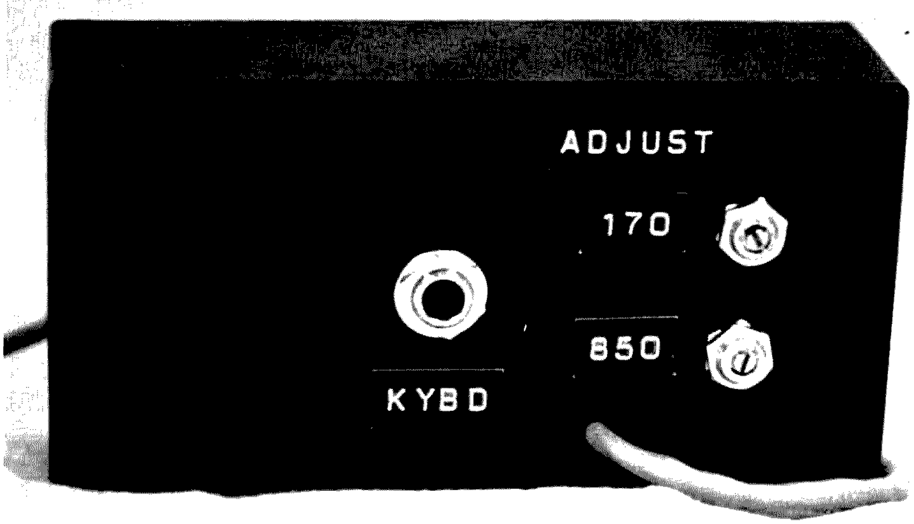
In the good old days (and when I say good old days I don't mean George M. Cohan days), the average ham had a CW or CW-AM (remember that?) transmitter and a separate VFO. For those enterprising enough to try radioteletype (RTTY), a simple diode keyer applied to the cathode of the oscillator tube (another oldie-but-goodie) would produce a frequency shifted signal. Those wanting to do some background reading, or who may still have a separate VFO and wish to try the old way, should refer to an excellent discussion of a "shift-pot" circuit in *QST*, May, 1965. Irv Hoff, a RTTY pioneer,



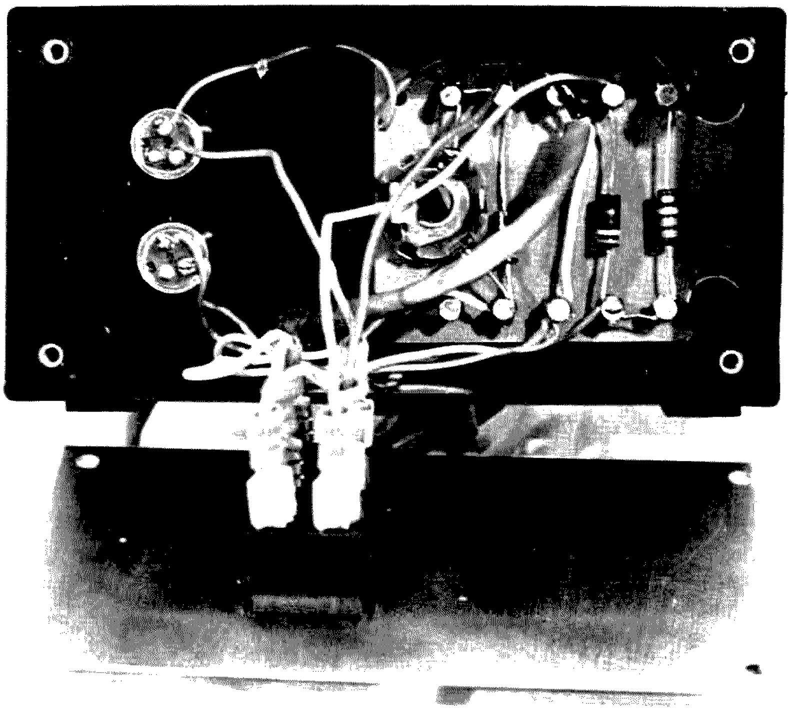
had a series that year which is required reading for anyone contemplating RTTY. If you are going to use the old, but venerable, shift-pot circuit, then you are excused from reading the rest of this article, and may drool at the ads elsewhere in this magazine. If not, stay with me.

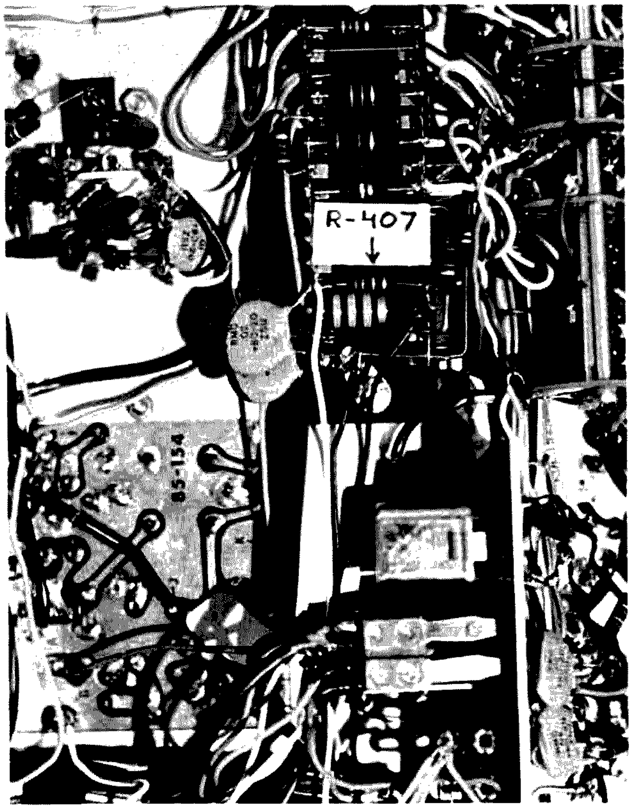
Not too many years ago, a new beasty, SSB (or SSSC, as it was first named) hit the airwaves. In order to put one of *those* on RTTY, you had two alternatives: Either use the rig as an expensive CW transmitter and use a shift-pot circuit, or inject audio tones and shift them, thus producing FSK at the output. Again, Hoff's landmark *QST* series goes into much detail on this. The AFSK input approach is certainly simple, but unless the transmitter is perfectly "clean" with regard to unwanted sideband and carrier, and the audio tones are perfect sine waves, all sorts of spurious signals can result. The end effect is to make us use the SSB rig as a CW transmitter, and fall back on the shift-pot.

Enter a new era. With the SB-400/401, Heathkit introduced the ham to the Linear Master Oscillator. Unlike the VFO, the LMO is said to be linear over the entire band, making frequency readout and calibration a cinch. Only one hang-up: The LMO is *sealed.* How can you transmit FSK? Until now, the only way has been the audio input (AFSK) method. This article details a method for frequency shift keying these transmitters that is easier than using the old shift-pot.

In order to maintain the same frequency on upper and lower sidebands, and still get the audio filtered through a mechanical filter to generate said sideband, it becomes obvious that some means of shifting the LMO frequency must be inherent in the system. The "BIAS" input does just that. By shifting the bias, the frequency of the LMO is shifted several kHz. Now, all we have to do is shift the bias in step with the desired FSK signal, and reduce the magnitude of the shift to 850 Hz, 170 Hz, or whatever is desired.

The circuit, shown in Fig. 1, does just that. Bias voltage for the LMO is derived from the junction of R404 and R407. A ground is established through Ra and Rb, with Rb shorted on "mark" – producing a high frequency. In order to make the circuit practical, a means of selecting





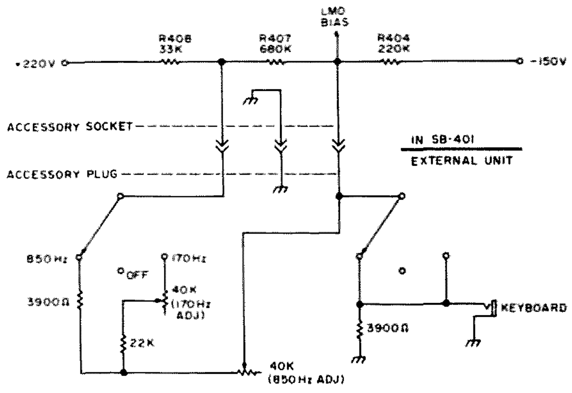


Fig. 2. Frequency shift keyer.

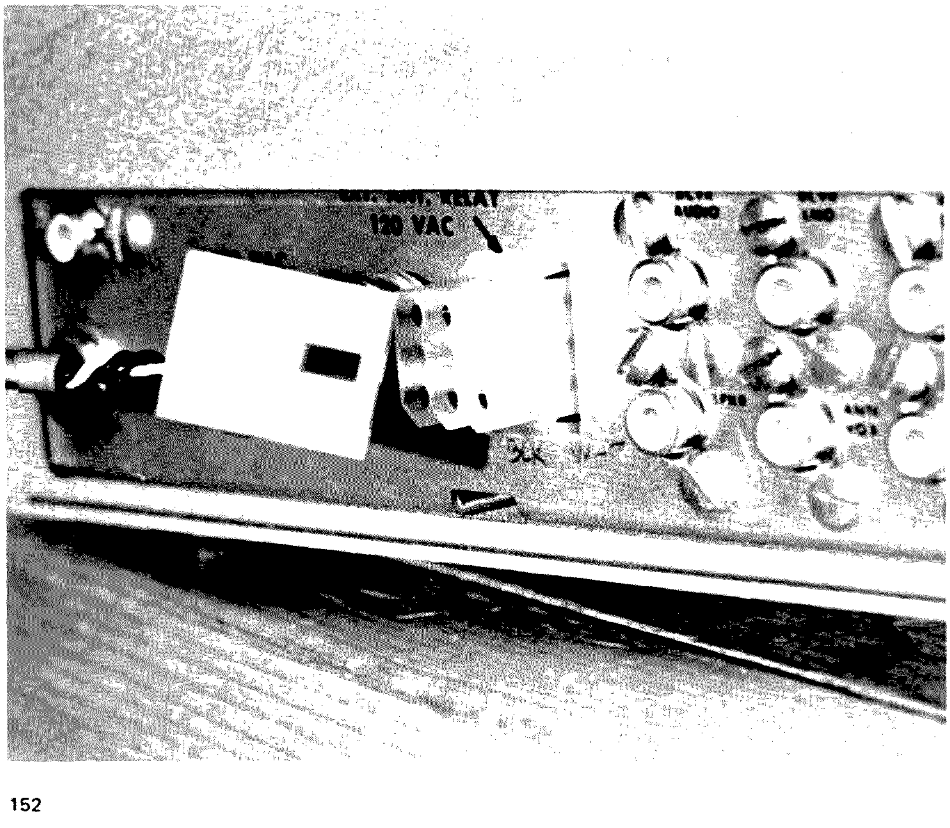
shifts, and disabling the circuit for SSB operation, is necessary. These additions result in the final circuit, Fig. 2. Keying for the FSKer must be done "dry," with clean contacts. This makes direct keyboard or loop keying impractical. A polar relay, or better yet a magnetic reed relay, may be used. For a discussion of the magnetic reed relay in keying, see my article, "AFSK Revisited," in the January, 1974 issue of *73 Magazine*. In it I go into the how and why of reed-relay keying.

Connection to the SB-401 is made on the underside, at Terminal Board No. 2. R407 is available there, and leads may be run from each side, and ground, to the accessory socket in the back. If you have lost the connectors for the socket, they are available from Heath, or in many parts stores (Waldom/Molex .093" Mating Pin Terminals, No. 1381-80). The unit may then be plugged in or unplugged as desired.

Calibration and operation are as with any FSK network. With the keyboard contacts in "MARK" condition, zero the transmitter to the desired frequency. Open the keyboard contacts and adjust the appropriate potentiometer for either 850 Hz or 170 Hz shift. The transmitter should be loaded to only 100 Watts or so, rather than the full 175 Watts, as long continuous transmissions are not conducive to final tube health. Cutting back from 175 Watts to 100 Watts is less than a 3 dB change, anyway. A straight key plugged into the key jack will serve as both a transmit/receive switch and a means to identify the station on CW.

Although the slant of this article has been directed toward the use of FSK for RTTY, any variable modality may be introduced to produce a corresponding frequency shift. Rather than use audio tones, an enterprising SSTV enthusiast might find herein a way to produce that peculiar signal in a novel way.

At any rate, I hope this method can find wide application, and get more of you out there on the green keys. ■



Social Events

DUNSEITH ND
JULY 10-11

The 13th Annual International Hamfest will be held July 10 and 11, 1976 at the International Peace Garden between Dunseith, North Dakota and Boissevain, Manitoba. This year it will be held in the Canadian Pavilion. Excellent camping, contests, prizes, party, dance and meetings. For information write WBØGFZ or VE4OD.

SANTA MARIA CA
JULY 11

The Satellite Amateur Radio Club is sponsoring the Santa Maria Amateur Radio Picnic And Swapfest to be held on Sunday, July 11th, 1976, beginning at 12 noon at the Newlove-Union Oil Picnic Grounds on Orcutt Hill. Watch for the signs marking the turnoff, 1 mi. south of Clark Ave. on US 101. Talk-in will be on 146.52 and 7280 kHz.

The highlight of the event is the Santa Maria style barbecue, to be served at 2:30 pm. All the meat, salad, beans, bread and salsa that you can eat. Soft drinks will be available, but bring your own beer.

The main door prize is a Tempo One 80-100 meter transceiver. Other prizes, too. Swap tables available at $3.00 each.

The meal alone is well worth the drive from L.A. or the central valley. Tickets are only $5.00 for adults/$2.50 under 12, and can be obtained by sending a check made out to Santa Maria Swapfest, Route 1, Box 55A, Santa Maria CA 93454.

Please obtain tickets in advance so that enough meat can be ordered.

SOMERSET KY
JULY 11

The Lake Cumberland Amateur Radio Association's hamfest will be held Sunday, July 11, 1976 at 10 am at the Somerset Outdoorsmen's Club, Somerset KY 42501. Lunch will be available.

CHARLESTON SC
JULY 11

The Charles Towne Hamfest will be held at the Gaillard Municipal Auditorium on Sunday, July 11, 1976, in Charleston SC. Registration is $2, which includes a door prize ticket. Activities include an indoor flea market, displays, home brew contest, CW copying contest, historic tours, and a special program on the Marconi Wells Fleet Wireless Station. Saturday activities include QCWA, MARS, S.C. SSB Net Banquet, and a hidden xmtr hunt. Talk-in on 34/94 and 3915. For further information write — Charles Towne Hamfest, Box 4555, Charleston SC 29405 or check into the S.C. SSB net on 3915 at 7 pm local time.

CORUNNA MI
JULY 17

The Shiawassee Amateur Radio Association (SARA) of Owosso, Michigan is hosting the Michigan Buzzards Roost and Emergency Nets picnic and sponsoring the 2nd annual SARA Swap and Shop at McCurdy Park, Corunna, Michigan. Early Bird get-together Saturday evening, July 17, Swap and Shop, picnic on Sunday, 8 am to 5 pm, July 18. Free admission, tables for Swap and Shop $2.00, tickets available for drawings, overnight trailer and camping space available. Talk-in on 3930 kHz, 146.52 MHz with repeaters on 147.63/.03 and 449.30/442.10 MHz. For further information, write SARA, 1302 W. Main St., Owosso, Michigan 48867.

FLOURTOWN PA
JULY 18

Picnic. Friends of WR3ABE bring family and food, noon, Sunday, July 18, 1976 at Fort Washington Park, Flourtown PA.

TERRE HAUTE IN
JULY 18

Turkey Run Hamfest has MOVED! New location is the Vigo County Fairgrounds on Highway 41 just South of Terre Haute. There will be prizes galore, lots of flea market space under a roof, XYL Bingo, and plenty of overnight camping will be available. Presale tickets are available 4 for $5 or $1.75 ea. At the gate 3 for $5 or $2 ea. For further information or tickets write to Wabash Valley Amateur Radio Assn., P.O. Box 81, Terre Haute IN 47808.

PORTAGE IN
JULY 18

The Lake County Amateur Radio Club's 2nd annual hamfest is July 18 at the Isaac Walton League in Portage, Indiana. Take I-94 to Ind. 249 exit, then north on Ind. 249 ½ mile. Tickets $1.50 advance, $2.00 at gate. Write: Herbert S. Brier W9EGQ, 409 S. 14th St., Chesterton, Indiana 46304.

SLATER MO
JULY 24-25

The Antique Aircraft and Amateur Radio Show will be held Saturday and Sunday, July 24 and 25, 1976 at the Slater Memorial Airport. Registration $1 in advance: $1.50 at the door. Buffalo burger feed Saturday night and Sunday noon. Talk-in 3963 kHz, 146.94 and 146.28/.88. For additional information and advance tickets write Dale Beilsmith WØKNF, 807 North Broadway, Slater MO 65349, (816) 529-2173.

CROSSVILLE TN
JULY 24-25

The Oak Ridge Amateur Radio Club, Inc., Annual Crossville Hamfest will be held in Crossville TN on July 24-25, 1976 at the Cumberland County Fairgrounds. Technical forums will be at the Holiday Inn on July 24 and the banquet will be at Holiday Hills Country Club on Saturday night with a Breeder Reactor Program planned. Sunday, July 25, features a picnic, flea market, raffle of many valuable prizes, and "eyeballing your friends" at the fairgrounds.

CANTON OH
JULY 25

The Tusco Amateur Radio Club and the Canton Amateur Radio Clubs are holding their Second Hall of Fame Hamfest on July 25, 1976. It will be held at the Stark County Fairgrounds, Canton, Ohio. This weekend, by the way, is the weekend of the National Pro Football Hall of Fame Football Game and Parade.

PITTSBURG KS
JULY 25

The annual Pittsburg Repeater Organization hamfest and watermelon feed will be held on Sunday, July 25, 1976 at the Lincoln Park shelters in Pittsburg, Kansas. Location is at 10th Street and Bypass 69 intersection. There will be a covered-dish picnic, transmitter hunts, swap meet, and lots of prizes including many for the YLs and harmonics. Talk-in will be WRØADZ 34/94 and 52/52.

FLAGSTAFF AZ
JULY 30-AUG 1

The Ft. Tuthill Hamfest will be held July 30-31 and August 1 at Flagstaff, Arizona at Coconino County Fairgrounds across I-17 from airport. R-V and tent camping. Three days in the tall cool pines. Swapmeet, tech sessions, contests, prizes, pot luck, and exhibits. Talk-in 146.22/82, 146.34/94, 146.52 and 3992 kHz.

WEST MILFORD NJ
JULY 31-AUG 1

The 550 Amateur Radio Club and Oakland Repeater Association will hold its annual hamfest/picnic at the Westbrook Park Kampgrounds, West Milford, New Jersey on July 31 and August 1, 1976. All amateurs, their families and guests are invited. Talk-in via club repeater WR2AHD 147.49 MHz/146.49 MHz and 223.34 MHz/224.94 MHz. For additional information contact Mark Kirshner WA2HLE, 73 Page Drive, Oakland, New Jersey 07436, phone (201)-337-0316.

WASHINGTON MO
AUG 1

The Zero-Beaters ARC will hold their annual hamfest on Sunday, August 1, at Washington, Missouri City Park. Free parking, auction, and bingo for the XYLs. No admission fee or fee for parking in the traders row. Many prizes including station accessories, books and a handmade quilt. For info or tickets contact Al Lanwermeyer WNØQBS, or Zero-Beaters ARC, WAØFYA, Box 24, Dutzow, Mo. 63342.

LEVELLAND TX
AUG 1

The 11th Annual Northwest Texas *Emergency Net* swapfest and picnic will be held in the City Park in Levelland, Texas on Sunday, August 1, 1976. Bring your own picnic basket. Free registration begins at 0900. Lunch at 1230. Swapping all day. Tables are provided. This event is for the entire family and is jointly sponsored by the Hockley County Amateur Radio Club and the Northwest Texas Emergency Net. Mobile talk-in frequency is on two meters only on 146.28-88 Mc., the Levelland Repeater: WR5AFX.

ANGOLA IN
AUG 1

Attention Midwest Amateurs! August 1, 1976 at the Steuben County Fairgrounds near Angola, Indiana will be the annual Fort Wayne Repeater Association FM picnic. Flea market, fun and prizes. Tickets are $1.50, children under 12 free. Talk-in frequencies will be 146.16-.76, .28-.88, .52 and .94. For further information contact Jerry Prumm W89FOC, PO Box 6022, Fort Wayne, Indiana 46806.

MT LEBANON PA
AUG 1

Western Pennsylvania — the 39th Annual Hamfest of the South Hills Brass Pounders and Modulators will be held on August 1st, from noon until dusk, at St. Clair Beach, Upper St. Clair Township, 5 miles south of Mt. Lebanon on Route 19. Swap and shop, picnic space and swimming for the family. Mobile talk-in 29.0 and 146.52. Information and pre-registration at $1.50 per ticket ($2 at door) from Fred Schreiber K3FIW, 181 County Line Road, Bridgeville PA 15017. Vendors must register.

MACK'S INN ID
AUG 6-8

The Wyoming - Idaho - Montana - Utah Ham Club would like to announce that the 44th Annual WIMU Hamfest will be held August 6-8 at Mack's Inn, Idaho just 20 miles west of Yellowstone National Park. There will be a full line of activities including our famous breakfast under the pines. Camping on the grounds is available plus motels, cabins and restaurants. Pre-registration is $6 per person, $1 for children under twelve. For registration or more info contact: WIMU, c/o Larry Jacobs WA7ZBO, 5655 So., 4060 West, Salt Lake City, Utah 84118.

OKLAHOMA CITY OK
AUG 7-8

The Oklahoma Ham Holiday and State ARRL Convention will be held Saturday and Sunday, August 7 and 8

in Oklahoma City, Oklahoma. The meeting will feature the largest flea market in the Southwest, special programs, technical seminars, equipment displays, and unique activities for the ladies. For information and advance registration write Oklahoma Ham Holiday, Post Office Box 20567, Oklahoma City, Oklahoma 73120.

SAUK RAPIDS MN
AUG 8

The St. Cloud Radio Club Annual Hamfest will be held on Sunday, August 8, 1976, from 10 am till closing, at the Sauk Rapids Municipal Park. Free parking and overnight parking, hot dogs and pop available. Swapfest and ham gear sale. Talk-in on 34/94 and 3925. Hope to see you all there. For further info, contact Bill Zins WAØOTO, St. Cloud Radio Club, PO Box 752, St. Cloud MN 56301.

FT. WASHINGTON STATE PARK PA
AUG 8

The Mt. Airy VHF Radio Club (the Packrats) are holding their annual family picnic in the Flourtown Area of the Fort Washington State Park on Sunday, August 8, 1976 (rain date 15 August). Talk-in via W3CCX/3 on 52.525, 146.52, and 222.98/224.58 MHz.

CONCORDIA KS
AUG 8

Hamfest – Cloud County Community College, Concordia, Kansas, August 8, 1976. Swimming, tennis, and radio-controlled model airplanes for the kids. Events for the XYLs. Prizes, meetings: 2 meter, ARRL, MARS, satellite. WØFNS Award, ham auction. Lew McCoy will speak at August 7 banquet.

PETOSKEY MI
AUG 14

Straits Area Radio Club Swap and Shop will be held August 14 from 8 am to 4 pm at Emmet County Fairgrounds on US 31, ½ mile west of southern junction of US 31 and US 131, in Petoskey, Michigan. All amateurs, CBers, SWLs, S1 admission, 50¢ per table, door prizes, lunch counter, free parking. Talk-in on 3.920 MHz, channel 1, 146.52 MHz.

EAST RUTHERFORD NJ
AUG 14

The Knight Raiders VHF Club's auction and flea market will be held on Saturday, August 14th, at St. Joseph's Church of East Rutherford, Hoboken Road, East Rutherford. Free admission, free parking, refreshments available. Talk-in will be on 146.52. Doors will open 10 am. Flea market tables: $6 for a full table, $3.50 for half a table. Reserve your tables in advance by writing to The Knight Raiders VHF Club, K2DEL, PO Box 1054, Passaic NJ 07055.

NEW CASTLE DE
AUG 15

Delmarva's new annual hamfest will be held August 15, 1976 at Wilmington College, New Castle, Delaware – U.S. Route 13 just north of Delaware Route 141 in New Castle, New Castle County. Tail-gating $2.50 per space. Rummage and display tables $5 per table. Food and camping available. Ladies' Bingo. Admission $1.75 advance – $2.50 at gate. Children are free. Make all checks payable to Delmarva Hamfest Inc. Mail all requests for reservations and information to John Low K3YHR, 11 Scottfield Drive, Newark DE 19713.

HUNTSVILLE AL
AUG 15

The North Alabama Hamfest will be held on Sunday, August 15 at The Mall in Huntsville, Alabama. A hamfest supper will be held on Saturday night. Events include prize drawing, flea market, ARRL forum, MARS meetings, displays, and XYL programs. Talk-in on 146.94 and 3965. For more information contact N.A.H.A., PO Box 423, Huntsville AL 35804.

SPRINGFIELD MO
AUG 22

The Southwest Missouri Amateur Radio Club will hold its annual hamfest, swap meet and family picnic on August 22, 1976, at Lake Springfield Park. This picnic attracts over two hundred radio amateurs and their families from southwest Missouri, northwest Arkansas, southeast Kansas, and northeast Oklahoma each year. For more information write: James A. Crooke, Secretary, Southwest Missouri Amateur Radio Club, 1601 South Kimbrough Avenue, Springfield MO 65807.

AURORA IL
AUG 22

The Fox River Radio League W9CEQ Hamfest will be held August 22, 1976 at beautiful Phillips Park, east edge of Aurora, U.S. Hwy. Rt. #30. All day family fun, picnic, zoo, lake and flowers. Same old price – $1.00 advanced with SASE to FRRL, PO Box 443 Aurora IL 60507. Talk-in on 146.94.

ATLANTIC CITY NJ
AUG 28-29

The Personal Computing '76 Consumer Trade Fair will be held August 28-29, 1976 in Atlantic City, New Jersey. Seminars and technical talks, major exhibits, demonstrations, door prizes, and free literature all about software and hardware development, microcomputers, memories, comparisons, interfacing, implementation, AMSAT, computerized music, video terminals, construction, printers, games, and tapes. Admission $5 advanced, $7.50 at door (includes exhibits and seminars). Exhibition booths – call (609) 927-6950.

LA PORTE IN
AUG 29

The combined La Porte County Amateur Radio Clubs will hold their Fall Hamfest on Sunday, August 29th, 1976 at the La Porte County Fairgrounds in La Porte, beginning at 7 am Chicago time. Overnight camping available. Indoors in case of rain. No table or set-up charge. Paved midway, good food and drink. $2 donation at the gate. For more information write: PO Box 30, La Porte IN 46350. Talk-in on 01-61 and 94 simplex.

SO DARTMOUTH MA
AUG 29

The Southeastern Amateur Radio Club is having a Flea Market and Picnic on August 29, 1976 at the Stackhouse Fairgrounds in So. Dartmouth MA. Space will be $2 and table an additional $2. Homemade food, magic show for the children, and

many raffles. For a flier write: Arthur Sylvia, 317 Nemasket St., New Bedford MA 02740.

MENA AR
SEPT 4-5

The Queen Wilhelmina Hamfest 1976 is Saturday and Sunday, September 4 and 5, at Queen Wilhelmina State Park, Rich Mountain, Mena, Arkansas. Excellent accommodations and food at the newly restored historic Queen Wilhelmina Castle. Door prizes hourly, grand prize, new equipment displays, flea market, camping area with utilities and rest rooms, amusements for harmonics. Talk-in 146.52. For more information write WB5CXX, P.O. Box 5191, Texarkana TX or phone (214) 838-0625.

DANVILLE IL
SEPT 5

The Danville Hamfest will be held at Douglas Park, Danville, Illinois September 5. Downstate Illinois' largest. Great prizes. Advance tickets $1.75 ea., 3/$5 with an SASE to Jim Wilson, 308 First, Ridgefarm IL 61870. Talk-in 22/82 and 3910.

MELBOURNE FL
SEPT 11-12

The 11th annual Melbourne, Florida hamfest will be held Saturday and Sunday, September 11-12, 1976, from 9 am to 5 pm each day in the air-conditioned Melbourne Civic Auditorium located on Hibiscus Boulevard. Donation is $2.50 per adult. Full program includes forums, meetings, auction, swap tables, commercial exhibits, awards, prizes, etc. Talk-in on 25/85 and 52/52. Sponsored by Platinum Coast Amateur Radio Society. For more info write PO Box 1004, Melbourne FL 32901.

FINDLAY OH
SEPT 12

The 34th Annual Findlay Hamfest will be held on Sept. 12 at Riverside Park, Findlay, Ohio. Talk-in 146.52. For advanced tickets and/or info write: Clark Foltz W8UN, 122 W. Hobart St., Findlay, Ohio 45840 (SASE please for under 5 tickets).

CHICAGO IL
SEPT 18-19

Radio Expo '76 will be held Saturday, Sept. 18 and Sunday, Sept. 19th at the Lake County Illinois fairgrounds, Routes 45 and 120 north of Chicago. Featured this year are an exhibit hall with dozens of displays by amateur manufacturers and distributors, forums with the FCC's John Johnston, *73*'s Wayne Green, ARRL, OSCAR and more. There's a giant flea market with both indoor and outdoor space, plus plenty of room for campers and trailers on the grounds. No waiting in line — the flea market opens Friday night for set-up. No extra charge, either. Talk-in on WR9ABY, 146.16/76, Chicago. Accommodations reserved at the Holiday Inn in Mundeline, Ill., a few minutes south of the fairgrounds. Mention Radio Expo. Advance tickets, $1.50 from Box 1014, Arlington Heights, Ill. 60006.

NEW KENSINGTON PA
SEPT 19

The Skyview Radio Society's Swap & Shop will be held on Sept. 19, 1976 at the Skyview Radio Club, New Kensington PA. Registration $1. Talk-in 52-52 and 04-64.

MOUNT CLEMENS MI
SEPT 19

The Fourth Annual L'Anse Creuse ARC Swap & Shop will be held on September 19, 1976 at the L'Anse Creuse High School in Mount Clemens, Michigan. Doors will be open from 0900 to 1500 EDST. First prize $200 cash. Talk-in on 146.52 and 146.94. Admission $1.50 at door, $1 in advance. For tickets enclose $1 and SASE and send to Robert Harder WB8ILI, 51769 Base, New Baltimore MI 48047.

NOTICE

We have received reports that W6JTT's "Simple VHF Monitor" (July, 1976, page 160) may interfere with certain kinds of aircraft instrumentation. While we continue to investigate this possibility, we suggest that readers refrain from constructing this converter.

petitioners all propose to increase the frequencies available to stations using type A4 or F4 (facsimile) emission. In RM-2170, petitioner asserts that ". . . (technology has) reached a point where the economical transmission of pictures is possible in a bandwidth no greater than a standard single sideband signal . . . Tests have indicated that it is even possible to transmit and receive high quality pictures in a bandwidth as narrow as 1900 Hz . . . " In RM-2330, petitioner claims ". . .the region from 51.0 to 52.5 MHz is largely unused in current practice." Several reasons are cited as justification for this claim, including the present rule which limits the bandwidth of an F3 emission to the same maximum bandwidth of an A3 emission. This, it is claimed, has also had an adverse effect on the growth and development of repeater stations in the 52 to 54 MHz band. In RM-2429, petitioner asserts that "ASCII, American Standard Code for Information Interchange, has become the most popular mode of mechanical and digital encoding for both computer and communication teleprinter applications due to greater character and function versatility." The rules presently authorize only the use of the International Telegraphic Alphabet No. 2 five-unit (start-stop) teleprinter code for amateur teleprinter stations at standard speeds of 60, 67, 75, or 100 words per minute. In RM-2550, the American Radio Relay League, Inc., proposes to delete all references to teleprinter operating speeds and to permit the use of any of the standard codes in military or commercial usage. In RM-2507 and RM-2545, petitioners propose to permit operation of amateur television repeaters on frequencies in the 420-450 MHz band which are not presently available for repeater stations.

4. Rather than further complicate the present rules with additional provisions to accommodate the petitioners' requests, we are herein proposing to delete all references to specific emission types in Part 97 of the Rules. We propose, instead, to replace the present provisions with limitations on the permissible bandwidth which an amateur signal may occupy in the various amateur frequency bands. Within the authorized bandwidth limitations, any emission type would be permitted.

5. We propose that maximum permissible bandwidth increments be established as follows: less than 0.35 kHz, less than 3.5 kHz, less than 35 kHz, or 35 kHz or more. Each Amateur sub-band would have an appropriate maximum permissible occupied bandwidth. For instance, Morse code and teleprinter emissions would generally fall within the 0.35 kHz bandwidth sub-bands. Telephony, facsimile and slow scan television emissions using conventional single sideband techniques could operate in the 3.5 kHz bandwidth sub-bands. Double sideband amplitude modulation, narrowband frequency modulation and independent sideband emissions would be excluded from these sub-bands. However, these emissions using conventional amplitude modulation or frequency modulation techniques could operate in the 35 kHz bandwidth sub-bands. In addition, any other emissions that satisfy the bandwidth limitations would be permitted on all appropriate amateur frequencies. We also propose to establish a finite limit on the maximum permissible output power of all emissions outside the authorized occupied bandwidth, including spurious modulation products, harmonics, parasitic oscillations, etc. Because of a significant increase in activity in the 420-450 MHz band, we propose to limit the maximum authorized bandwidth in this band to 35 kHz. Since adoption of this proposal would eliminate the use of fast scan television, we invite comments as to what useful purpose is served, other than experimentation, by transmission of television signals in the Amateur Service.

6. The Commission is aware that some amateurs desire to use modes of emission which are not specifically provided for in the rules. We hope, through this proceeding, to produce amended rules which will encourage amateurs to develop and implement techniques for more efficient utilization of the radio spectrum, and to increase service to the public through the establishment of improved communications systems. Many new and unusual emission types will eventually appear on amateur frequencies as a result of these amendments. It should therefore be noted that the provisions of Section 97.117, which prohibit the use of codes or ciphers for the purpose of obscuring the meaning of the communications, will remain in effect. However, the employment of signals encoded solely for the purpose of facilitating communications would be permitted under the revised rules. In order to facilitate identification of stations using these emissions, we are proposing a minor change to clarify the present rule for station identification which would continue the requirement for use of either the international Morse code or unencoded telephony.

7. The specific rules changes proposed herein are set forth in the attached Appendix II. Authority for these proposed amendments is contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended.

8. Pursuant to applicable procedures set forth in §1.415 of the Commission's Rules, interested persons may file comments on or before June 23, 1976, and reply comments on or before July 23, 1976. In accordance with the provisions of §1.419(b) of the Commission's Rules, an original and eleven copies of all statements, briefs, and comments filed shall be furnished the Commission. All relevant and timely comments and reply comments will be considered by

the Commission before final action is taken. The Commission may also take into account other relevant information before it, in addition to specific comments invited by this Notice. Responses will be available for examination by interested parties during regular business hours in the Commission's public reference room at its headquarters in Washington, D.C. (1919 M Street, N.W.).

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

APPENDIX I

Petition Number	Petitioner
RM-1429	James L. Turrin
RM-2163	Jerome C. Grekowsky
RM-2170	Howard M. Krawetz
RM-2330	Gordon Schlesinger
RM-2429	Raymond E. Heimberger
RM-2507	Bruce J. Brown
RM-2545	Biagio Presti for Aptron Laboratories
RM-2550	Robert M. Booth, Jr., for The American Radio Relay League, Inc.

APPENDIX II

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

1. In §97.7, sub-paragraph (d)(2) is amended to read as follows:

§97.7 *Privileges of operator licenses.*

* * * * *

(d)(2) Radio telegraphy using the international Morse code is authorized in the frequency bands 3700-3750 kHz, 7100-7150 kHz (7050-7075 kHz when the terrestrial location of the station is not within Region 2), 21,100-21,200 kHz, and 28,100-28,200 kHz.

* * * * *

2. In §97.61, the headnote, paragraphs (a) and (c) and sub-paragraphs (b)(11) and (b)(13) are amended to read as follows:

§97.61 *Authorized frequencies and bandwidth.*

(a) Following are the frequency bands and associated bandwidth available to amateur radio stations, other than repeater stations, subject to the limitations stated in paragraph (b) of this section, §§97.65, 97.109, and 97.110.

Freq. band	Max. auth. bdwdth (kHz)	Limitations (see par. b)
kHz		
1800-2000	3.5	1,2
3500-3775	0.35	-----
3775-4000	3.5	4
4383.8	3.5	13
7000-7150	0.35	3,4
7075-7100	3.5	11
7150-7300	3.5	3,4
14000-14200	0.35	-----
14200-14350	3.5	-----
MHz		
21.000-21.250	0.35	-----
21.250-21.450	3.5	-----
28.000-28.500	0.35	-----
28.500-29.700	35.0	-----
50.000-50.100	0.35	-----
50.100-54.000	35.0	-----
144.0-144.1	0.35	-----
144.0-148.0	35.0	-----
220-225	35.0	5,6
420-450	35.0	5,7
GHz		
1.215-1.300	-----	5
2.300-2.450	-----	5,8
3.300-3.500	-----	5,12
5.650-5.925	-----	5,9
10.000-10.500	-----	5
24.000-24.250	-----	5,10
48.000-50.000	-----	-----
71.000-76.000	-----	-----
165.00-170.00	-----	-----
240.00-250.00	-----	-----
Above 300.00	-----	-----

(b)(11) The use of an authorized bandwidth in excess of 0.35 kHz in this band is limited to amateur radio stations located outside Region 2.

* * * * *

(b)(13) The frequency 4383.8 kHz, telephony using single sideband amplitude modulation with reduced or suppressed carrier, maximum power of 150 Watts, may be used by any station authorized under this part to communicate with any other station authorized in the State of Alaska for emergency communications. No airborne operations will be permitted on this frequency. Additionally, all stations operating on this frequency must be located in or within 50 nautical miles of the State of Alaska.

(c) The following transmitting frequency bands and the associated bandwidths authorized in paragraph (a) of this section are available for repeater stations, including both input (receiving) and output (transmitting):

FREQUENCY BAND (MHz)
29.5-20.7
52.0-54.0
146.0-148.0
222.0-225.0
442.0-450.0
any amateur frequency above 1,215 GHz.

3. In §97.65 the headnote, (a) and (b) are amended, and (c), (d), (e) and (f) are deleted

to read as follows:

§97.65 *Bandwidth of emissions.*

(a) Occupied bandwidth is the frequency bandwidth such that, below its lower and above its upper frequency limits, the mean powers radiated are each equal to 0.5 percent of the total mean power radiated by a given emission.

(b) The authorized bandwidth is the maximum occupied bandwidth authorized to be used by a station.

§97.69 [deleted]

4. §97.69 is deleted.

5. In §97.73, the headnote and text is amended to read as follows:

§97.73 *Purity of emissions.*

The mean power of emissions on any frequency removed from the upper or lower limit of the authorized bandwidth, by more than 250 percent of the authorized bandwidth, shall be attenuated at least 40 decibels below the peak output power of the transmitter.

6. In §97.87, paragraph (h) is amended to read as follows:

§97.87 *Station identification.*

* * * * *

(h) The identification required by paragraphs (a), (b), (c), (d) of this section shall be given on each frequency being utilized for transmission and shall be transmitted either by telegraphy using the international Morse code, or by unencoded telephony, using the English language. If an automatic device is used for identification by telegraphy, the code speed shall not exceed 20 words per minute. The use of a national or internationally recognized standard phonetic alphabet as an aid for correct telephone identification is encouraged.

7. §97.93 is amended to read as follows:

§97.93 *Modulation of carrier.*

Except for brief tests or adjustments, and authorized remote control or experimental purposes, an Amateur station shall not transmit an unmodulated carrier on frequencies below 51.0 MHz.

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20554
FCC 76-348
40050

In the Matter of

Amendment of Part 97 to make special callsigns available to stations licensed to Amateur Extra Class operators.
Docket 20092

FIRST REPORT AND ORDER
Adopted: April 14, 1976

By the Commission:

1. A Notice of Proposed Rule Making in the above captioned matter was released on July 2, 1974, and published in the Federal Register on July 8, 1974 (39FR24922). In that Notice, the Commission proposed to amend Part 97 of the Rules and Regulations to permit an Amateur Extra Class licensee to request specific unassigned callsigns for his primary and/or additional stations. It was also proposed to discontinue the availability of "in memoriam" callsigns, i.e., callsigns requested by Amateur club stations for the purpose of honoring a deceased member.

2. In this First Report and Order, we will address only the issues of 1X2 (i.e., so called two letter) callsigns and "in memoriam" callsigns. We will defer consideration of 1X3 and 2X3 callsigns to a later Report and Order. The recent tremendous influx of Citizens Radio Service applications at our Gettysburg, Pa., licensing facility precludes the implementation of any changes in the Amateur callsign structure which would require significant additional manpower or changes in the computer software systems. Because the number of available 1X2 callsigns is small, we believe the changes adopted herein will not impose an undue processing burden, and the manpower released from the processing of "in memoriam" callsigns can be used in this effort.

3. Approximately 150 comments were received by the Commission in this matter, and all were carefully considered. The overwhelming majority of the comments supported our proposal regarding choice of specific callsigns by Amateur Extra Class licensees. The comments were divided approximately equally between those who wished to retain a specific time period before becoming eligible for a 1X2 callsign, and those who desired to completely delete the waiting period. One of the most frequently raised objections was that the proposal would permit Amateur Extra Class operators who had been licensed only a short time to obtain 1X2 callsigns. (1X2 callsigns are presently issued to Amateur Extra Class operators who submit evidence that they held an amateur license at least 25 years prior to the date of application.) In the words of the American Radio Relay League (ARRL), "Two letter (1X2) callsigns traditionally have identified the holder as an 'old timer,' one who has devoted many years of dedicated public service as an amateur. To make two letter calls available to any Amateur Extra Class licensee irrespective of years of service would have the practical effect of downgrading the stature of present two letter callsign holders."

4. Those supporting our proposal without qualification cited the incentive a 1X2 callsign would provide. Comments suggested that the special significance of a 1X2 callsign would encourage many amateurs to upgrade their license class and thereby increase their overall technical and operational pro-

ficiency. Other comments indicated that longevity is not always an indication of a proficient operator with much public service, and therefore is not a valid criterion to use for the assignment of a 1X2 callsign.

5. We believe that the arguments for retaining a large measure of tenure associated with 1X2 callsigns have limited merit. Traditionally, 1X2 callsigns have been available only to those persons who have been long-term amateurs. Such callsigns, because they are in very short supply, must necessarily be rationed in some manner, and it has seemed the fairest procedure to allot them consistent with some measure of longevity. However, we also believe that once the "old timers" have had an adequate opportunity to obtain 1X2 callsigns, whatever such callsigns remain should be made available progressively to more recent licensees.

6. Accordingly, we have determined to phase out the tenure requirement in the following manner: All present Amateur Extra Class holders of 1X2 callsigns will be given an exclusive 3 month period to request a different specific 1X2 callsign. During this period, we will also accept applications for specific 1X2 callsigns from Amateur Extra Class licensees who were first licensed at least 25 years ago and who do not now hold 1X2 callsigns. At the end of this period, we will then also begin accepting applications for specific 1X2 callsigns from Amateur Extra Class licensees who first obtained that class of license prior to November 22, 1967 (the effective date of Docket 15928). Such applications will be accepted for a period of 3 months, at which time we will then also begin accepting applications from Amateur Extra Class licensees who first obtained that class of license prior to July 2, 1974 (the release date of Docket 20092). Such applications will be accepted for a period of 3 months, at which time we will then also begin accepting applications from Amateur Extra Class licensees who first obtained that class of license prior to July 1, 1976 (the effective date of Docket 20092). Such applications will be accepted for a period of 3 months, at which time we will then also begin accepting applications from any Amateur Extra Class licensee.

7. Many comments expressing agreement with our proposal also expressed concern over the administrative problems which could arise in implementing a working system. Inevitably, a single callsign will be requested by more than one applicant, and there are essentially two ways to handle such situations: 1) on the basis of which of the amateurs has been licensed the longest (or the earliest); or 2) on the basis of which request was received first for processing. Considering the manpower available for handling application processing, we have no alternative but to adopt the latter approach. To do otherwise would tremendously delay the processing of all amateur applications, Amateur Extra Class and others. Moreover, because we will permit an applicant to request several callsigns in order of preference, there should be few instances where an applicant cannot get a callsign of his choice, although it may not have been his first choice. All applications for specific 1X2 callsigns should be filed on a Form 610, with an attachment listing the callsigns desired, in order of preference, and should be sent to the FCC offices in Gettysburg, Pennsylvania. The filing fee is $28 if no renewal is desired, and $29 if renewal is desired.

8. We are adopting an effective date well beyond the release date of this Report and Order, and we will not accept prematurely filed applications. This will insure that the news of this rule making will reach most amateurs so that they will have sufficient time to gather the necessary information and application forms required. We recommend that requests for verification of past records and license dates not be directed to the Commission. Amateurs may seek licensing information in Commission files at our Washington, D.C., offices, or they may request such information via our duplication contractor. Requests for such information made to the Commission will be honored. However, because of staff limitations and other priorities, such requests are not likely to receive immediate attention and could be delayed, thereby causing a loss of position in the filing sequence. Additionally, to insure that applicants requesting 1X2 callsigns fully comply with the requirements for licensing background documentation, we would like to clarify exactly what must be submitted. An applicant may submit either an original license, a photocopy of an original license, or a photocopy of a recognized listing or source, such as the Radio Amateur's *Callbook*. When such a source is used, the applicant should include a photocopy of the title page of the source which indicates its title, and dates of coverage. We cannot accept affidavits or sworn statements from applicants, since they cannot be verified.

9. As proposed, we are deleting the availability of "in memoriam" callsigns. Less than a dozen comments directly addressed our proposal to delete the availability of such callsigns, indicating a general lack of interest among the many commentors. Arguments stated that since there were a relatively small number of requests, the additional manpower and 1X2 letter callsigns which would be gained from the deletion would be minimal. While we realize the "in memoriam" station may indeed be a tribute to a deceased amateur, we have found instances of abuses of such callsigns. In our Notice of Proposed Rule Making, we cited the difficulty in many instances of determining whether or not the evidence of the deceased's membership in the applicant club is valid. While most comments agreed that the burden of proof should lie with the applicant, no comment indicated a valid and

conclusive method of verifying the submitted evidence. Additionally, it is seldom, if ever, that a non-1X2 callsign is requested, although many more 1X3 and 2X3 callsigns have been issued to the Amateur population as a whole. It appears that, in some instances, the objective of the club to honor a deceased member is secondary to obtaining his prestigous 1X2 callsign for club use. We will therefore issue no such callsigns henceforth, but will continue to renew those now outstanding.

10. In view of the foregoing considerations, we find that the amendments to Part 97, set forth in the attached Appendix, are in the public interest, convenience, and necessity. The authority for such amendments is contained in Sections 4(i) and 302 and 303 of the Communications Act of 1934, as amended.

11. Accordingly, IT IS ORDERED, that effective July 1, 1976, Part 97 of the Commission's Rules and Regulations IS AMENDED as set forth in the attached Appendix.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

APPENDIX

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

1. Rule Section 97.51(a) is amended to read as follows:

§97.51 Assignment of callsigns.

(a) * * *

(1) A specific unassigned callsign may be reassigned to a previous holder thereof.

(2) A specific unassigned callsign may be temporarily assigned to a special event station.

(3) One unassigned 1X2 callsign (a callsign having one letter, then the numeral, followed by two letters), may be assigned to the station of a previous holder of a 1X2 callsign.

(4) One specific unassigned 1X2 callsign may be assigned to the station of an Amateur Extra Class licensee who previously held or presently holds a 1X2 callsign.

(5) One specific unassigned 1X2 callsign may be assigned to the station of an Amateur Extra Class licensee who submits evidence that he held any amateur radio operator or station license, issued by any agency of the U.S. Government or by any foreign government, 25 or more years prior to the receipt date of an application for such assignment.

(6) Effective October 1, 1976, one specific unassigned 1X2 callsign may be assigned to the station of an Amateur Extra Class licensee who submits evidence that he first held that class of license prior to November 22, 1967.

(7) Effective January 1, 1977, one specific unassigned 1X2 callsign may be assigned to the station of an Amateur Extra Class licensee who submits evidence that he first held that class of license prior to July 2, 1974.

(8) Effective April 1, 1977, one specific unassigned 1X2 callsign may be assigned to the station of an Amateur Extra Class licensee who submits evidence that he first held that class of license prior to July 1, 1976.

(9) Effective July 1, 1977, one specific unassigned 1X2 callsign may be assigned to the station of any Amateur Extra Class licensee.

(10) The provisions of paragraphs (3) through (9) of this Section shall also apply to the issuance of 2X2 callsigns in Alaska, Hawaii, and U.S. possessions.

(b) * * *

2. Rule Section 97.53 is amended to read as follows:

§97.53 Policies and procedures applicable to assignment of callsigns.

(a) * * *

(1) 1X2 callsigns — callsigns with a single letter prefix and two letter suffix, e.g., W6AB, and 2X2 callsigns in Alaska, Hawaii, and U.S. possessions.

(2) 1X3 callsigns — callsigns with a single letter prefix and a three letter suffix, e.g., W6ABC.

(b) An eligible licensee will be permitted to hold only one 1X2 callsign. However, a licensee who, by reason of former rule provisions, presently holds more than one such callsign, may continue to hold those same callsigns in the same callsign areas.

(c) In those instances where an applicant is not eligible for a specific callsign, a 1X2 callsign beginning with the letter "W" will, subject to availability, normally be assigned to an eligible licensee.

* * * * *

(g) Subject to availability, a primary station will be issued the same type of callsign as the one relinquished upon modification of license to show a station location in a different callsign area.

(h) Except as provided in Section 97.51(a), licensees will not be assigned specific callsigns or counterpart callsigns (callsigns with identical suffix letters).

(i) Those Amateur Extra Class licensees eligible under the provisions of Section 97.51(a) for a specific unassigned 1X2 callsign may specify in their applications more than one callsign in order of preference. In those instances where none of the listed callsigns are available, the application will be returned without action unless the licensee has stated that he will accept, as a last choice, any unassigned 1X2 callsign.

(j) Callsigns which have been unassigned for more than one year are normally available for reassignment.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

WAYNE AT ATLANTA

About 15 minutes before the time scheduled for my talk, the small room was packed and the hall outside jammed in both directions. The talk was moved to the banquet room. It was estimated that about 350-400 sat in on it. I talked for over an hour and never once at any time mentioned the ARRL! That's not a new record . . . it's just that the League knows some of the things I *could* say and they are willing to suffer a lot of abuse from members to try to prevent that. I say bravo to the Atlanta HamFestival committee for getting me on the program. I think most everyone present had a good time during my talk.

The hamfest came off very well . . . quite an improvement from my last visit there a couple of years ago. I say three cheers for Chaz Cone and the committee for a splendid job. I didn't hear a single beef from anyone about their management.

Atlanta is well worth a visit, even from afar. It is a spectacle . . . and their amusement center, Underground Atlanta, is a lot of fun, too. The big ham dealers came in from all over . . . including a trailerload of ham gear brought down by Chuck Martin of Tufts Radio. The only sour note there was the theft of a Standard HT from the Tufts booth.

Watch out, Dayton!

FAST SHUFFLE FROM THE FCC

It's odd how long it takes the FCC to get around to acting on our petitions and how fast they seem to go on their own . . . weird. Like the recent 20777 bandwidth deal where the deadline for comments to be filed was way before there was any way for me to get the docket printed in *73* and out where you could read about it.

SOME THOUGHTS ON BANDWIDTH

Perhaps it was not by design that the FCC set its deadline for comments on the bandwidth docket at such an early date that little amateur dialogue was possible . . . and thus little opportunity for amateurs to help each other understand the ramifications of this docket . . . or to react intelligently to it. Though all of us are at times frustrated by the incredible amounts of time it takes for the FCC to react to our needs, it does seem as if certain functions, such as the time really needed for amateurs to develop a good reasoned response to a docket, are set too tightly. If the FCC wants to cut us out of the picture as far as our own rules are concerned, this is the way to do it.

I snapped in a petition to extend the deadlines so amateurs would at least have a chance to get their opinions in if they wanted to. They stretched out the comment period a couple of months, so you can put in your say. Read the thing over (see *73*, August, 1976, page 160), think about it a lot, and talk it over with your friends on the air . . . and then be sure you drop Uncle Charlie a note.

A few readers have asked me what I think about the docket and, though it may surprise you, I am not wholly without any opinions on the matter.

Now, to get down to some brass tacks on the bandwidth thing. The hot and heavy breath of the old-time CW operator seems to be at work here. I wonder what would have happened to CW if the Novice Class license hadn't been thought up? I also wonder if there is any real justification for the Novice ticket. I wrote a bit about that recently . . . expressing my idea that the Novice license is a cul-de-sac . . . and that it has effectively discouraged more people from continuing as radio amateurs than it has helped.

To repeat briefly . . . a Novice license encourages amateurs to try to learn Morse Code by the worst possible way . . . by gradually speeding up copy. This is fiendish . . . it drags out the learning process by many hours and makes it pathetically difficult to master . . . particularly that 10 wpm hump, which kills off so many who come up against it.

If you start right out learning the sound of each character at 13 wpm, then you never go through that misery of first *translating* each letter . . . then learning to translate them faster and faster . . . until you reach the operating speed of the brain . . . the 10 wpm hump . . . at which time you finally have to do what you should have in the beginning, learn automatic copy of the characters. Well, enough of that . . . it is the basis of the *73* code cassette course and why people using it are able to learn code so quickly. The ARRL code tapes use the time-dishonored slow method and drive people crazy.

If we didn't have the Novice license how much CW would we have in our ham bands? Once you remove the Novices and traffic nets, how much CW do you have? Not a lot . . . and this is why some of the phone ops have for some time been trying to get across the idea of re-allocating the phone/CW bands a bit.

With the rapid development of television typewriters, I shall be surprised if we don't begin to find RTTY growing substantially on our bands. And with microcomputers to help the RTTY systems, they should get to be very flexible. Since we expect this growth, we should give some thought now to what bandwidths are needed and how much of the band these systems will use.

The old standard of 850 Hz frequency shift, 60 wpm, Baudot (7-level) is on its way out. 170 Hz shift and 100 wpm at 7-level is more popular. And what is the bandwidth of a signal shifting 170 Hz and modulated by a 70 baud signal? (590 Hz, minimum.) Remember that you have to allow for at least third order harmonics if the square waves are to be received . . . possibly 5th order. Or should we go right away to ASCII (11-level) code? Since this is the way most modern equipment works, and we will need clumsy converters to use Baudot, ASCII is difficult to fight. ASCII at 100 wpm is 110 baud (830 Hz).

But why should we stay with 100 words per minute? Most information transfer is now happening at 300 baud or better. I suggest that the practical limit for information exchange is the reading speed of the receiving operator. There will be little use in transferring information at a much faster speed than it can be read for normal radio contacts. Perhaps we should consider this speed as our desired rate of information exchange.

Of course, there might be cases where you would want to send the information at a much higher speed . . . with a wider bandwidth . . . and then leave the transmitter off the air while the material is being read. In this way info could be sent in brief bursts. What we would lose in wider bandwidths, we would gain in time available for transmission.

I view the docket as a transparent device for banning AM from the low bands and ATV from 420 MHz, neither of which seems like a good move to me. If you've read my editorials for very long, you know that there are few amateurs who are less in favor of AM on the low bands. I've been the enemy of the AM kilowatt since sideband appeared in the early 50s. But I don't like to kill off

everything that would get the axe along with AM by making the rules to kill AM. I firmly believe that amateurs should have the freedom to experiment and pioneer new modes and techniques, so if there is not an awfully good reason for setting limits on experimentation, I think they should be left open.

Just to perhaps enter a slight doubt in the minds of those who are so emotionally upset by AM that they are quite willing to throw out the baby with the bath water (to coin a phrase), let's suppose that some group started working again with double sideband suppressed carrier systems, complete with a relatively simple IC synchronized receiver detector. Suppose this system was demonstrated to enable amateurs to operate on phone with very little interference as close as 500 Hz, thus permitting about seven times as many contacts to take place in a given band as with SSB? Would you want to throw this out just to get rid of a tiny handful of old buzzards who are making trouble on 75m with bad language and arrogant behavior? This is one of the biggest problems with the proposed bandwidth docket.

Do we want to force most RTTY and SSTV to occupy the crowded phone bands while much of the CW channels are going begging? In view of the coming interest in microcomputer-assisted RTTY and SSTV, which could be the biggest interest ever in amateur radio ... even bigger than FM and repeaters ... we might be painting ourselves into a corner (to coin another phrase).

Any precipitous rush into a bandwidth plan for the amateur bands will only give us that much more that we have to undo later on. It seems to me that before we can make any intelligent decisions on such matters we need to open up amateur dialogue about how much of the sub bands we want for CW, how much for phone, how much for other modes such as RTTY, SSTV, FAX, and the coming things which amateurs are pioneering these days.

It has been suggested that perhaps a bandwidth ruling would not be the best solution to the need for room for more modes ... that perhaps it is getting time to pay more than lip service to de-regulation and consider taking off the restrictions to pioneering. We could just open the ham bands in the U.S. as they are in many other countries ... any mode, anywhere. Then we could set up agreements among ourselves if we want to reserve some frequencies for CW DXing ... CW rag chewing ... CW traffic nets. We were able to do this with FM and repeaters on two meters ... without any help from the ARRL or FCC. (The recent attempts by the League to take over FM and repeaters have been rejected by a great many regional repeater groups.)

SELF-POLICING?

One of the aspects of amateur radio which has gotten a lot of lip service from the FCC — and little recognition other than that — has been the self-policing function.

You want proof? Amateurs with any memories at all will recall that much of the activity of the FCC with regard to amateur radio has been in issuing pink slips. If the FCC had contacted the ham magazines and asked them to pass along the word that they would prefer that amateurs do thus and so, amateurs would have gladly done what was expected. But instead, suddenly there is a rash of pink slips for not announcing the call area when mobile. That's how we found out about the FCC wanting that. Phooey.

If you want a child to act like a child, treat him like a child. If you want him to accept responsibility and act more grown up, just treat him accordingly. The same thing holds for amateur radio. I think we can, for the most part, be reasonably adult if we are given the opportunity. If the FCC will give us responsibility, I think we can handle it.

We don't need to go crying to the FCC every time we have a problem. When over-enthusiastic CBers take a turn at trying to use the 10m spot on their dial, we need to let them know immediately that this is a great big no-no. It won't hurt to get the name, address, and as much other data on the offender as possible, complete with some tapes in case you and your fellow local amateurs fail ... but you should exhaust every avenue of approach to the problem before crying to the FCC.

CAN AMATEURS ACCEPT RESPONSIBILITY?

We have a lot of nerds in our ranks, I agree. But thank heavens the percentage is miniscule. It is just possible, if you and I assert ourselves, that we can keep things running smoothly.

As proof that we can, we only have to look back at the development of FM repeaters less than 10 years ago. The early days of repeaters were rife with repeater wars and a lot of very bad things that most of the pioneers would prefer to forget. There was little standardization of repeater channels. It was a mess. With the help of a lot of articles in *73*, the *Repeater Bulletin*, and a series of Repeater Symposiums, the field was brought together and repeater groups formed into repeater councils, committees set up to coordinate frequencies and a national agreement made on channels and standards.

By the time the FCC came out with repeater regulations, amateurs had already solved their problems and two meter FM was virtually troublefree. The repeater rules were so far out of line with what was needed that amateurs reacted strongly. The January, 1974, hearing before the FCC, the first of its kind in history, allowed amateurs from all over the country to speak directly to the FCC Commissioners and tell them that we were being over-regulated. This hearing had a tremendous impact on the FCC and particularly on John Wiley, who was soon to become the Chairman of the Commission.

Wiley felt that the FCC would rule better by ruling less, but he needed a group to use as a demonstration of what could be done. When amateurs went to the trouble to come in and tell the FCC they wanted less regulation, it was at a very fortunate time ... here was just what the FCC needed to show what could be done.

If I may put in a bad word here about the ARRL ... they opposed the hearing and refused to participate in it. I moderated the hearing. After the hearing a League lawyer took us out to lunch and explained that we were naive about how things are done in Washington. Maybe.

Okay, so we did a good job of getting FM organized and working, all without any help from the FCC at all. Does this mean that we can handle our low bands? Frankly, I don't know. FM, by virtue of its short distances, perhaps put more peer pressure on big egos and tantrum throwers than might be possible on 40m. We could be getting into a lot of trouble ... but I think it is worth the gamble. With the support of the ham magazines I think amateurs can go from the small amount of self-policing they have today to almost total self-policing.

Try this on for size ... suppose we throw out docket 20777 entirely and all mode restrictions. This would mean that legally we would no longer have CW bands or phone bands, just ham bands. It would be up to us to set "gentlemen's agreements" on frequency use. I think we could do it. Before you disagree with me, and I know you will, remember back to the beginnings of SSB. There we had an agreement which put SSB stations on the top end of the 20m phone band. Sure, we had a few bad guys who broke the agreement, but 99% of the operators lived by it and it worked. Only the demise of AM ended the agreement.

And don't forget the monumental set of agreements which were put together to allow FM and repeaters to work!

CONSTITUTIONAL CONVENTION

We need cooperation between ham magazines ... something that has been sadly missing in the past. I've tried many times to get something going, but the fear of Wayne Green is so strong at ARRL that I sometimes think they would sacrifice the whole hobby rather than cooperate. I shall keep trying. I shan't try to be Mr. Nice Guy with them ... I couldn't be that deceitful. But hopefully our goals are similar ... the betterment of amateur radio. I get a bit depressed when I see what the League has brought about, such as Incentive Licensing, the greatest fiasco in the history of the hobby ... their refusal to accept transistors for years, their refusal to accept FM and repeaters until recently ... etc.

Hopefully the past is the past and all that bad stuff that has been done can be put aside and we can all work toward a better tomorrow. I'd like to see a national convention of amateurs about every two years where delegates from ham clubs can get together for about a week and change our self-made rules. Committees could be set up as at the ITU in Geneva. The committees would then report their recommendations to the whole convention and a vote would be taken on all rule changes. Amateurs would then live by the new rules until the next convention.

I'd like to see ARRL get into something like this. I sure don't want to have to splinter myself further by trying to organize it or trying to start a new club which could do something like this. I have my hands full trying to run *73*, fighting my little battles with government agencies and phone companies, messing with computers, putting out books, and even getting on the air now and then! I also get out to conventions and hamfests ... a little DXpeditioning ... visits to advertisers ... it keeps me busy, if not out of trouble.

Let's see ... I was writing about bandwidth ... frankly, I'd like to see the lid taken off for a year for a test of our maturity. If we could hack it, I think it would allow the widest possible latitude for pioneering ... and, like it or not, that is one of the ways we pay the freight.

Speaking of pioneering ... every time I've devoted an inordinate part of the magazine to something new as a way of encouraging pioneering in that field, I've had flack from reactionaries. Yes, I know that most hams just sit there and rag chew and don't want to know nothin' about computers. Well, you tell them that it is pioneers and emergency operations that keep them in rag chewing frequencies and that not only shouldn't they sit there and bitch about it, they should darned well see that any magazine which is in there helping them hold onto their hobby is supported to the fullest ... even if they are too lazy to sit down and educate themselves on new techniques. Okay?

Actually, I've had very little griping about I/O ... but I know darned well that a lot of old curmudgeons are out there grumbling ... they think it is clever to try to tear things down and be destructive. They're too dumb to make any creative contributions to amateur radio ... etc.

Every time I get on the air I thank heaven for the amateurs who get out there and do things ... the ones who are the spark plugs for field day outings ... for contests ... who run ham clubs ... who set up training classes for new hams ... who set up and run repeaters ... who build new circuits and then write 'em up for one of the ham magazines ... who see to it that nets meet and work ... who handle traffic ... who are there when an emergency comes and keep at it until all is clear ... who try new

Thoughts from the Bull-etin Board

Every school age kid is well aware of the industrial revolution and how it affected our country's growth in the late 1800's. The microprocessor revolution seems to be upon us and it looks like it might last for a while. Motorola believes that the microprocessor revolution has only started. They predict that the total effect will continue to be felt for 200 years. Microprocessors reduce costs to a level which allows them to be used in applications never before considered economically practical.

A quartz crystal watch with LED or liquid crystal display (LCD) is a small version of the microcomputer. They are programmed at the integrated circuit (IC chip) manufacturer's plant rather than being programmed by a person sitting at a keyboard with a CRT display. Some of the more expensive quartz watches are programmed to fit a four year cycle. That is, they are aware of the day of the month, including February, but they automatically take care of leap year when February has 29 days. Then the watch resets itself and it is good for another four years. During that time, the watch has kept track of the fact that it has counted 4 times 10 to the 12th cycles of the quartz crystal. But just once every four years the circuit is activated so that it counts and displays the time for 29 February! A quartz watch on the wrist is actually more accurate and stable than the broadcast band AM transmitters, a BC transmitter being allowed 20 hertz drift (2 parts in 10 to minus 5th) while the quartz watch has an accuracy of 2 parts in 10 to minus 6th. An added benefit of the LED display is that it can be used to locate keyholes in the dark!

As research continues in the area of the light emitting diode (a truly solid state lamp or light source), they shed more light. I recently received a green LED from Siemens (type LC-57-D) which is able to put out 30 millicandelas at a current of ten milliamperes. When they first came out a few years ago, they put out about .5 millicandelas at 20 mils of current. At a rated 60 mils of current, the green LED is bright enough to cast a cone of light like a prefocussed flashlight bulb. And green is at the maximum of the human eye so it appears much brighter. The red LED has maximum output at a frequency where the response of the eye is only 10% of that at green.

Have you thought about what effects a local lightning storm might have on your solid state electronic devices? Consider this. During a lightning storm, voltages in excess of ten million volts and currents of thousands of Amperes are generated and discharged from cloud to cloud and from cloud to ground. It is at these times that diodes, transistors, and triacs may fail even though the electronic device may not even be turned on. There is not yet much in the technical literature on the subject of lightning-induced electronic failures, but it may well be a design consideration of the future. There has been some data however, in the current issue of *The Electronic Technician* and the *RCA Transistor Manual*. It seems that power line-induced voltage transients may cause transients in the solid state power supply and take out the diodes associated with the power supply. Several instances reported to me concern a sewing machine and a tape recorder. After the last lightning storm (of which there were many in San Antonio in April '76), the sewing machine would operate only at full speed and not operate at variable speeds as before. Either a diode or triac in the speed control circuits has had its operating voltage exceeded. And thinking back, I noticed that my Radio Shack Timekube (5, 10, 15 MHz) receiver would no longer function. And it is battery operated (9 volts) but I was using an outdoor antenna lying on the ground (an exhausted beverage longwire). I noticed later that if I turned the audio way up and listened closely, I could still hear WWV very weakly. That meant that the transistor in the front end had gone out during one of the recent storms. So go back in your memory to see if your electronic device didn't fail after a lightning storm (even though you may not have noticed it till many days later). Seems like a good article for some electronic magazine!

Touching Minds

Peculiar to amateur radio is its concern with direct and instant communication among people, near and far, of whatever nationality and race. Flying, diving, philately, mountain-climbing and many other hobbies are essentially adventures of private experience, but ours turns on mutual disclosure.

What we have achieved in this free commerce of ideas has not brought peace to the world, but remember that for perhaps only one tenth of one per cent of the time passed since man was a rootless nomad have we known the miracle of wireless contact — international exchange without intermediaries. We have just begun. It was only minutes ago that fires along the hilltops served to signal the approach of an armed host, and that was a top priority message.

Today our technology is a fascinating maze, continually branching in new directions, but still the ultimate goal is to touch another mind, and it always will be. CW or phone, teletype or ATV, even computers — these are but means and the end is communication for the progress of human affairs.

Belt Tightening

The FCC has just released Docket No. 20777, the latest step in the "deregulation" program. Let us examine the immediate effects the proposal would have on amateur operation in the lower frequency bands.

1. Conventional AM, double sideband (reduced or suppressed carrier), and narrow band FM would be prohibited.
2. SSB and SSTV signals would be much more severely restricted in terms of permissible bandwidth than at present. Independent sideband simultaneous transmission of SSTV and voice signals would apparently be precluded.
3. Wide shift RTTY would be forbidden in the present CW bands, but wide and narrow shift forms of FSK would be allowed in the "phone" bands.
4. MCW (A2 emission) would be legal on all frequencies in the HF bands.

The style of reasoning that must have gone into this proposal reminds me of the "doublethink" which George Orwell describes in *1984*, in which the government insists that "War is Peace; Ignorance is Strength; Freedom is Slavery." Now, outlawing AM, DSB and NBFM and applying strict bandwidth limits to SSB and other modes is deregulation.

Our bands are not critically overloaded by present amateur usage. With the increase in popularity of VHF FM, the HF phone bands have become significantly less crowded in recent years. Of course, we do not know what we will have as frequency allocations after 1979. But today, specified bandwidth limits are neither necessary nor desirable. It would work undue hardships on many amateurs to be forced to abandon their present rigs. We should wait until after the WARC to decide if we need rigid belt tightening.

LETTERS

OWING

Here's some dough for yet another of your code tapes.

I bought the 5 and 6 wpm tapes when I joined the Novice class being conducted by the 2 meter repeater club here in Beaumont. The 5 wpm tape was being used to drum the blasted code into us.

After missing one of the weekly classes, I arrived at the next class to find a stranger tuning up his beeper and saying something about a test.

I'd gotten pretty much through the 5 wpm tape, but hadn't even tried the 6 wpm and figured there'd be no way I'd pass the test. I took it just for laughs and turned it in on the theory that I might just pass.

Damned if I didn't.

So now I have this mainly unused 6 wpm tape. I'm waiting for the Friendly Candy Company to send my written test now, and I plan to work with that 6 wpm tape while waiting for the ticket so I won't sound like a dummy on the air. I've come by a Heath SB-101 and have put up a 40 meter dipole and am having fun listening.

One thing the other people in my class and I have noticed — these hams helping us get our Novice tickets sure are going to a lot of trouble just to help other people out. They're not getting anything out of it except satisfaction.

"Somebody helped me when I got into it," one of the instructors said. "This is the only way I can pay it back."

It's that attitude that I like the best about ham radio. Already I owe so much to so many people I can't even remember it all.

Richard Stewart

GETTING THE CALL

The Sterling-Rock Falls (Illinois) Amateur Radio Society was once again called upon by the local United Cerebral Palsy officials to provide communications for their annual WALKATHON EVENT. This event took place on May 15th.

The 20 mile march by grade school and some high school students got off to a start at 9:00 am and finished at 3:30 pm. The following volunteers in mobile units operated in 2 shifts and also helped to supervise the march: Paul Johnson K9BEF, Olli Ikonen WB9DNA, Bill Peters WB9MCZ, Dick Little K9EEH, Ed Fisher K9APD, and John Ordean WA9BSO. Other members assisting these units were Warren McMurry WB9DNR, Tom Carney WN9RXJ, Ken Weissenburger WN9RVY, and Dan Gryder WN9PSQ.

Several members of the Sterling-Rock Falls Amateur Radio Society and members of the Rock River Amateur Radio Club (Dixon) participated in the Sauk Valley Canoe Association race held May 16th, by providing communications from both land and boats along Rock River. This was a 14 mile stretch starting from Dixon, where the Dixon hams started and took over for a 7 mile stretch and then the Sterling-Rock Falls boys took over for the remaining 7 miles to the finish at the East End of Sterling at the boat marina. The Sterling-Rock Falls members were: Paul Johnson K9BEF and Jim Zeigler WA9NXE. The Dixon members participating were: Chuck Randall W9LDU, Phil Ogan WA9VCN, Darrell Webb K9JBX, Claude Ensinger WB9EBS, Neil Howell WA9OPS, Walter Martin WB4VWH, Sam Berard K9KNV, and Mike Heughes WB9GWU.

HOOKED

Keep up the I/O section. I'm hooked for sure. Since I wrote last, Dave K5WNV has his floppy disk and high speed printer up and flying. With the 24K memory and the disk we are really getting with it. Even running a fairly sophisticated Startrek. We're building both a RTTY and a video link from his shack to mine (25 miles). The video (439.25 MHz) works at short range, but we need more power to clear the hills between us. These hills are over 6000 feet high so you might call them mountains back there. We are running the VHF Engineering rig and modulator on page 28 of the June issue (beat you to it). Need a linear. Again keep it up.

WONDERFUL

I recently took advantage of your $17.76 subscription special, and I am including an order for 250 QSL cards. I first started reading *73* at the local library, and after I got my Novice ticket I decided to get a subscription to your wonderful magazine (even with the new format). I enjoy your magazine tremendously and get more good out of it than the other ham magazines. Keep up the FB on the articles and editorials.

SAVING THE SORCERY

I believe you have heard, or soon will, of the sailing sloop *Sorcery* emergency starting Saturday morning, May 8th. The 62 foot sailing vessel *Sorcery* took a 360 degree roll during a storm 1200 miles north of the Hawaiian Islands (42 degrees north, 162 degrees west). She was en route to California from Japan. Mabel W6YLT was aboard. Because of her roll over, she lost all power, masts, commercial radio gear, and life rafts. One crewman was swept overboard and was recovered, but was suffering from shock. Mabel's daughter suffered a compound fracture of the leg, and another crew member had a badly lacerated face. Below decks was a shambles. Mabel rigged an antenna and got a ham radio on 20 meters with battery power.

I thought I would fill you in on the first hour of the emergency:

I was operating on 14.323 in contact with WB9PRZ in Indiana, with my beam pointing east. KL7HAY, Harold (Hal) Berry in Homer, Alaska, heard us and broke in. Hal is a personal friend who winters in Sequim, Washington, and summers in Alaska. He had just moved up there a few weeks ago. His call in Sequim during the winter is WA7SQZ. During the 3 way contact, Hal (I believe his antenna was facing south) heard the distress call from W6YLT/mm region 2. He informed me and the other station. The Indiana station cleared and signed out. I turned my beam west and also picked her up. She was very weak, but between us we were able to get her location and condition. Hal said he would inform the Coast Guard. It turned out that he did not have a phone yet and had to go about a half mile away to reach one. While he was gone for about 20 minutes, I thought my correct job was to maintain communication with Mabel and keep the channel clear, which I did. I told Mabel that I knew KL7HAY had himself spent many years at sea and that I had complete confidence in him to notify the Coast Guard. WA6EAZ, Bill in San Francisco, heard me broadcasting the alert and broke in. He could not hear Mabel, so I asked him, because of his strong signal, to help keep the channel clear. He did a good job of this, moving above and below the frequency to keep other stations from QRMing. Then he got San Francisco Coast Guard on his phone patch. Hal got back to his rig by this time, and Bill patched both Hal and me into the San Francisco C.G. We filled them in and they notified Juneau, Alaska C.G., which would handle the search. Because Hal did not have a phone in his shack, Juneau Coast Guard called me long distance to confirm that it was no hoax and get further information.

At about the end of the first hour, Kodiak, Ketchikan and Widbey Island, Washington ham stations came on. They were all hearing Mabel somewhat better than we were, so we three, W7SRU, KL7HAY, and WA6EAZ, confined ourselves to a monitoring role and channel guard for the next 25 to 30 hours of the emergency.

I am happy to say that all through the emergency QRM was never a serious problem. All stations were cooperative, and stations whose services were needed at some times bowed out to monitor when they were not needed and remained quiet.

I think Hal KL7HAY should be commended for hearing that first Mayday. Mabel was very weak. We lost her for about 15 or 20 minutes, the boat was taking on water and I thought sure it had sunk. Then Hal's sharp ears heard her again.

Mabel should be commended for her calmness and proficiency during a difficult situation.

Bill WA6EAZ's phone patch for us into San Francisco Coast Guard really helped to get the ball rolling during the first half hour.

Fred A. Boggs W7SRU

WILSON GOOD GUYS

Better put the Wilson gang in Las Vegas on your "good guys" list! Perhaps on the top. Ordered a 5 Watt hand-held by phone on Monday, and it was here in Anchorage on Friday, all crystalled up and working "five by."

Air Mail of course! How's that for service!!!

Lt. Col. Herb Rosenthal KL7AE
Anchorage AK

MASTERPIECE

Received my July, 1976, *73 Magazine* today (May 29). Some service for sure.

Your editorial, "The Good, The Bad, The Ugly," was very interesting. Enjoyed every word. In my opinion, it is a masterpiece. Keep up the good work. I have been a ham 54 years this April and I am proud of it.

W. J. Gentry W5GF
Amarillo TX

BOTHERING THE DIEHARDS

I was interested in your I/O Editorial for July 1976 – particularly where you intend to set up cassette computer programs. Whenever you get set up to where you can show some typical simple computer setups where all you have to do is to plug in a TV monitor for readout, or cheap surplus teletype, and a cassette recorder, thousands of guys like me who are not computer hobbyists will buy them – or make them from kits. For what they do, not for what they are – what they do for us.

This will come about only if you get the programs wanted on cassettes. For the home trade, I think games are kid stuff. I'm busy enough – so are you – not to waste time with games. And not many of us run small businesses! Our major bookkeeping is balancing the bank account, and $5 calculators do that OK.

Program books – take a bunch of books on antennas and program them into an antenna cassette. With graphics if you can, even if the graphics have to be fed into an SSTV monitor.

A cassette on recipes – one for cooking fish, another for vegetarian vegetables, herbs and spices, etc. Microwave ovens – complementary vegs.

One on nutrition – vitamins, minerals, essential amino acids and enzymes – take the McGraw-Hill Nutrition Almanac for a starter. I know of a doctor who updates his computer with nutrition items twice a week from all known sources – and his is a pretty fee, around $300, to outline your initial program.

Cassettes on hints and kinks – there are so many books that this is endless. Get the writers of technical books together with programmers and you will come out with lots of cassettes – and buyers for lots of minicomputers!

We have a computer at our ATV repeater and any user can feed ASCII into his FM audio input and trigger it. You can get it to give you S-meter readings every few seconds with around 12 readings to a page, and updated as long as you run it – unattended. You can rotate your antenna, change antennas, change powers, and see the results from the computer. There is nothing like it – though the FCC would like to take it away from us. And it bothers no one – but a few diehards in the FCC.

Arlington VA

BRAVE "BRONKO"

I almost applied for a position on your "way out" *73* staff, but decided to have a brain operation instead. (I have Dystonia Musculorum Deforman, a rare disease, and have an appointment at St. Barnabas Hospital, Bronx NY, for brain surgery. So wish me luck and I'll be looking forward to each and every issue with the same excitement as always.)

I have had the opportunity to get to meet and speak with W2NSD/1 at the 1974 and 1975 Dayton Hamventions. At present, however, I speak and walk like a drunk because of my disability. Since it is progressive at this stage, I'm sure he was only showing his PR side and was certainly not impressed – although I was. Very much so. I certainly wish he knew the tremendous amount of energy it took for me to elbow my way through the crowd from the parking lot to the booth to have the honor to meet and shake hands with such a brave "bronko," although I'm sure he did not understand a third of what I was trying to say. My energy level has gotten so low that I could not make it to this year's Dayton Hamfest. If I could have, Wayne would have had to put up with my persistent effort to be friendly and be understood. MAYBE IF AND WHEN I HAVE BRAIN SURGERY I'LL BE ABLE TO WALK, TALK AND BE MORE NORMAL, AS OTHER PEOPLE. Then look out, sir, for I shall be able to be understood and I'll verbally twist your ear off. Thank you for reading this (if you got this far).

Jack E. Foster W8JYE

READY

It was a typical heading-home-from-work crowd on WR4ACN, the Chesapeake-Norfolk, Va. repeater, on the afternoon of May 20. Suddenly, at 1645, K4IIV broke in with an emergency request for amateur portable units to coordinate a foot search for two runaway teenage girls who were feared lost in a highly woody and swampy quicksandish area just south of the Norfolk Naval Shipyard in Portsmouth, Va.

WA4MMP mobile, who was about 5 miles from the scene, immediately took charge, and rapidly established an emergency net soliciting operators with 19/79 hand-held equipment. Within 15 minutes, 5 mobile units with hand-held capability were on their way. These included WA4PRU, WB4MBS, WB4AXY, WB2KEA and WB2KLL. Shortly thereafter, WB4OHZ was on his way and W4THN and WB4WSU were en route to the South Norfolk Airport to take up a light plane with a handie-talkie to assist the foot units. Five other volunteer stations were on the air and waiting at home should they be needed in the field.

By 1815 all units including the aircraft were on the scene, and the search began through the half mile by half mile wooded swamp area. The ground and air units were coordinated by WA4MMP mobile, who had positioned himself with the search organizers midway along the search area frontier. For the next hour and a half an extensive foot/air search was conducted without results, and the operation was secured at 2000 (dusk). The two girls were spotted by police the next day in Hampton, Va., and safely returned to their homes.

Although the operation was unsuccessful in locating the girls (they were not in the searched area), it was an excellent example of how amateur radio operators and their VHF repeater systems can respond quickly and efficiently to their communities in times of need. We know that next time we're called, we're ready!

William R. Shaw WA4MMP
Chesapeake VA

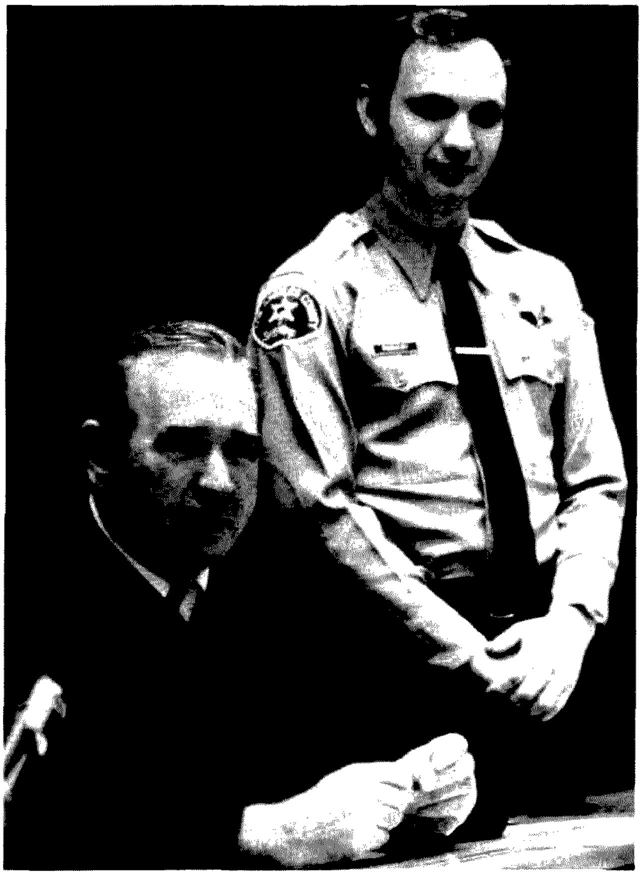
SHOCKED

I just received my July issue of *73*, and I was shocked when looking through it. On page 46 there was an advertisement for a citizens band radio, which is deplorable to put in a magazine whose readers are hams and expect to find information on amateur matters. This includes both articles and advertisements.

I first subscribed to *73* because of the number and quality (both are high) of your articles, but the reason you guys would stoop so low as to CB ads in a ham magazine is beyond me. Wayne, I hope your desk has been flooded with letters like this, and I think you have some explaining to do.

John Pilson AA1UZK
Box 27
Saunderstown RI 02874

Nope, John . . . it's a flood of just a few letters. I've tried several CB rigs in my car and the Standard Horizon 29 is fantastic . . . substantially better than the others, so I was



SMALL WORLD

After months of QSOing each other on 2 meter mobile en route to downtown Los Angeles, Bill W6ONC (left) and Andy WA6WXD (right) discovered, to their amazement, that they were Judge Ritzi and Bailiff Romanisky in the very same Superior courtroom each day! Prior to that, they were unaware that they even worked in the same building.

Lenore Jensen W6NAZ
Sherman Oaks CA

happy to see it advertised. Apparently you are not one of the first to get the word on how CB has changed in the last couple of years . . . hopefully a reader or two will drop you a letter and bring you up to date. I just wouldn't drive without CB these days, as it is very valuable. I use it to get road directions, say hello to people along the road (including the fuzz), keep track of traffic problems, etc. Further, most of the new hams these days are coming from CB, so a bigoted attitude toward this group is odd, at best. FCC estimates are that we might well hope for over a million CBers to join amateur radio in the next couple of years. I think we need all the hams we can get on the CB bands. That way we can keep bugging them with the "next step" of hamming — Wayne.

BYE-BYE TVI

I own a three decker three family house and I had TVI with one of my tenants, and a neighbor, who also lives in a three tenement house, one block away. I thought it very peculiar that one tenant should get it, and others not, but subscribed to the popular thinking of insufficient shielding in the i-f of the TV sets. As it happens, in these three decker houses the 220 V ac is brought in to a main box, then is taken to serve three 110 V ac lines. The only way to do that is 2 on one side and one on the other side. After a lot of fuses renewed at the main box, I investigated the cause, and came to the conclusion that I needed a heavier service line in, plus heavier fuses. Being a cheap guy, I sought another way, and that way was to have my tenant taken off my side of the line, and put with the other tenant. Even then, I did not realize that I had done anything remarkable until my tenant said to me, "I cannot listen to talk any more. I liked to hear gossip over the radio. I could tune you in anytime I wanted — now I can get no more news." I am slow on the uptake, so it took two days for it to sink in that the greatest interference is by the power lines. Anyone using the service from the same side of the power line that you are on is 90% liable for TVI. If the amateur is giving trouble to his neighbors (who are surely using the same pole transformer and the same side of the line as the amateur), then all he has to do is *change over to the other side of the 220 V ac line.*

Of course one would say then that he would get another crop of TVI neighbors, but it is hardly ever so. The contractors who put up houses, and the electricians, use the same rule of thumb: The front part of the house goes on one side of the line, the back part on the other. I have passed on this information to the local hams, and it works. So now I am sending it to you to pass over to *hamdom* in your magazine.

MAKING PLANE'S

I've been lookin tru Ben Franklin's May issue & as per usual it's jus loaded with lot's a info. However, last night arnd 9 I was talkin 2 an HRO dn in the Santa Cruz Mtns on 2 M with my Clegg an my 270 Vertical antenna & a HRO broke in saying that when I was tru he'd like a word with K6OPG . . . it turned out that he'd jus flu in fom SINGAPORE 2 days before, & Doc Charan 9V1NR, my ol friend had tol Ed, this HRO, that if he'd ever hrd Kenny K6OPG 2 please say hello 4 him & 2 tell me that it was abt time 4 me 2 come out & pay him a visit 4 a few weeks, as it hasn't been since 1972 since I've visited him & SINGAPORE (the best Country in the World) . . . Well, I haven't hrd Charan 9V1NR on the Ham bands lately, but then I'm jus Not on the air all of the time. Nevertheless, I'm making plane's 4 my visit (& it won't be via a 747 like the last time that I flu into SINGAPORE complements of my MARS ID card in my wallet, but that another story. This time I'll probley take a few years in getting there, as I jus bought a 32' diesel powered sailboat & I'm sholy learning how 2 navagate fr Leanard Davis W6LZA who's a marine engr that jus happens 2 be on the beach at the presant time & over the week-end wer installing some bronz plate's 4 my radio grounding system I'll need 4 my VHF & low-band ATLAS that I plan 2 use aboard. But, I'm out of paper, but will keep U informed.

Kenny Mahoney K6OPG
San Francisco CA

ON TOP

I'd like to bring your attention to the American military amateurs in D-land. You've heard the DA calls on the bands. Through the attentions of DA2BA/WA5LVT, I took my Tech exam and now am waiting for the results to filter back through the federal maze. Activities of this sort, coupled with clubs like the Wiesbaden Amateur Radio Club, with its multinational membership, make amateur radio in Germany an exciting deal.

In reference to *73 Magazine*, it was the first I read, and none can top it.

Dale LeDoux
Mainz, Germany

LIMARC ATV

LIMARC will shortly put on the air an experimental amateur radio television repeater from the top of the Plainview tower at the Long Island Expressway and Sunnyside Blvd. This repeater will have a center of radiation of 550 feet above sea level and an estimated service radius of forty miles. Its input frequency is 439.25 MHz and it will output at 427.25 MHz, with an effective radiated power of 500 Watts.

This ATV program is planned to be a pioneer operation in the metropolitan New York area for sociological electronic uses of interactive audio visual communication (by radio) through simple home terminals and publicly located terminals (such as in schools, library community rooms and the Hall of Science at Flushing Meadow). Conceivably, operations such as this can usher in a completely new dimension in community educational activity and thereby generate a new radio service of undreamed potential and promise.

We in LIMARC are committed to this program and plan to also explore through this repeater operation other experiments utilizing narrow band high definition slow scan frame grabbing techniques and computer access by remote keyboard through radio links.

HURRICANE WATCH

I wish to inform all concerned that the Hurricane Watch Net will be operating on the frequency of 14325 this year. Also, this frequency will be used for emergency traffic (*only*) if and when it is deemed necessary. Other traffic such as health and welfare will be handled on other frequencies as in previous years (the YLISSB, Intercontinental Traffic Net, and IMRA, to mention a few, as well as other bands).

If any other information is needed, write or phone the manager, Phil J. Craig K4CRU, 115 S. Entrada, Hollywood FL 33021, (305)-983-4536, or myself.

LEMME TELL YOU!

Now just who do you think you're calling a "WN"? I got your 14 wpm tape *months* ago. Do you honestly think that I wouldn't have upgraded by now?

Here's how it happened: I got your tape in the mail and dropped everything to get it on the tape recorder. After about 2 minutes I got very angry at you, Wayne. Please, in the future, try to get the labels on the same side as the code. The code was on the opposite side. Hi, hi.

Well, when I finally found *that* out, the fun first began. The first two groups were okay, but after that — down the drain. Well, to make a short story long, I worked with that tape on the average of one half hour per day for about 6 weeks. Then one day I sat down, and, after being content with copying 5 groups in a row perfectly, I proceeded to copy one half of a loose-leaf sheet — without a single mistake!!! Lemme tell you, Wayne, that tape was really something.

For the technical part of the exam I used the General Class Study Guide which I got from a friend. Hey, thank the author for me, huh? I couldn't make head nor tail out of the License Manual at first, but after reading your book, I went back to the License Manual, and I actually understood what was there! Great!

I knew this Wednesday was it. (And boy was it ever; it was the first day of the new term and I got stuck with the worst seats in each class. Grrrrr.) Tuesday night I fell asleep saying, "You will not be nervous, you will do fine," over and over again.

Wayne, I woke up *so* nervous that morning I would have been happy pulling off a Tech. But finally my stomach settled down as I walked into the FCC office in New York. (I still can't figure out if it just settled down or was killed by that subway ride.)

After an incredibly long wait, we were taken in for our code tests. First they send you one minute of 13 wpm as a warm-up. Funny, it sounded more like 10 wpm. Hey, what are they trying to pull here. Ooops, here comes the real thing. Missed one. Missed another one. "Calm down," I tell myself. I reach the end of the page. I go back to fill In. Wayne, I think I filled in 2 letters in over 15 lines. That 13 wpm was nothing. That code tape really did the trick.

The written part of the General was just bordering on difficult, thanks to your book; the Advanced was even easier.

Well that's about it, Wayne. I'll let you (and everybody else, if this ever gets into print, which I seriously doubt) off the hook. Oh, just one more thing, I want to compliment you and your staff on a fine magazine (*73*, remember?). It never fails to mess up my schedule when it comes. I have to read it from cover to cover.

David M. Krumholz WA2YYL
Rosedale NY

P.S. I like your editorials.

A PLEA

This letter is a plea for more peripheral equipment to interface with the new family of microprocessors.

I have been working in data processing for over 20 years and have been following the development of the small processors. I can now pick up *73* or *Popular Electronics* and find pages and pages of advertisements for CPUs and RAMs at reasonable cost. But where is the I/O? I do not consider the TV typewriter display as an I/O device, but simply one for occasional communication by the operator with the processor. Well, what else do we have? Not much. Disk storage units are nice (nice and

CONTESTS

Editor:
Robert Baker WA1SCX
34 White Pine Drive
Littleton MA 01460

NOTE

Just received a note from K5MRU, who says the correct results for the 7th district in the 10-10 Net Winter QSO Party should have been K7PXI 83/207 and WB7AUJ 73/128, and WA7YCQ should have been omitted. Also, please note the date change by ARRL for the VHF QSO Party from the slow weekend of Sept 4th to the following weekend, making 4 contests for the weekend of Sept 11th!

KENTUCKY QSO PARTY

Starts: 000 GMT Aug 28
Ends: 000 GMT Aug 30
(full period)

SPONSOR:

Bluegrass Amateur Radio Club, Lexington, Kentucky.

EXCHANGE:

KY stations send RS(T), county, and consecutive QSO number. Other stations send RS(T), consecutive QSO number, and state, country or province.

SCORING:

One point per QSO. Multipliers for KY stations are total states, countries or provinces worked. Multipliers for other stations are total number of KY counties worked. A bonus multiplier of 1.5 may be taken if power input of 250 Watts or less is used.

ALLOWABLE CONTACTS:

One CW and one other mode per band. 6 and 2 meters to use simplex operation only.

SUGGESTED FREQUENCIES:

Lower edges of General HF CW and phone bands; also Novice frequencies.

LOGS:

Send logs by October 1 to Robert H. van Outer WB4YQY, 285 Hillsboro Ave., Lexington KY 40505. Appropriate awards will be presented.

FOUR LAND QSO PARTY

Starts: 1800 GMT Saturday, Sept 4
Ends: 0200 GMT Monday, Sept 6

This is the 7th annual QSO Party and is sponsored by the Fourth Call District Amateur Radio Assn. of the IARS. The same station may be worked on each band and/or mode fixed, and repeated again if operated portable or mobile from another county. Fourth call district stations may work other stations within the 4th call area.

EXCHANGE:

4th call area stations will send RS(T), state, and county. All others send RS(T) and state, province, or country.

FREQUENCIES:

Phone: 3940, 7260, 14340, 21360, 28600.

CW: 3575, 7060, 14070, 21090, 28090 (+/- 10 kHz).

Novice: 3710, 7110, 28110 (+/- 10 kHz).

SCORING:

4th call area stations score 1 point per W/VE QSO and 3 points per DX QSO (including KH6 and KL7). Final score is total points times total number of states and provinces (regardless of bands). All others score 2 points per QSO times the sum of the number of 4th district states and counties (count each state and county only once). For this bicentennial year, add 2 points for each CHC or FHC member worked. All CHC/FHC members will send their CHC or FHC number along with the report.

AWARDS:

Certificates to top scorers in each state, VE province, and country. Second and third place awards where scores warrant. High Honor Trophy Award (certificate) to high scorer in 4 Land, high W/K outside 4 Land, and to VE and DX country. Also county awards to 4th call area states and special awards to Novice, SWLer and blind-handicapped.

ENTRIES:

Mail logs with score within 30 days of end of party to 4th Call District ARA, Attn: Bob Knapp W4OMW, 105 Dupont Circle, Greenville NC 27834. Include an SASE for results.

ARRL VHF QSO PARTY

Starts: 1900 GMT Sept 11
Ends: 0600 GMT Sept 12

Rules same as June QSO Party; check August issue of QST for any last minute changes!

Entrants may operate no more than 28 of the 35 hours during the contest period. The seven hours off-time must be taken in increments of 30 minutes or more. Listening time counts as operating time. All contacts must be made on amateur bands above 50 MHz using authorized modes. Fixed, portable, or mobile operation under one call, from one location only is permitted. Any transmitter used to contact a station may not be later used to contact another station during the contest period with any other callsign. Contacts made by retransmitting either or both stations (such as repeaters) do not count for contest purposes. Each contact exchange must be acknowledged by both operators before either may claim contact points. A one-way confirmed contact does not count.

EXCHANGE.

Simply exchange your ARRL section.

SCORING:

On 50 or 144 MHz count 1 point per QSO, on 220 or 420 MHz count 2 points per QSO, and on higher UHF bands count 3 points per QSO. Final score is then the total QSO points multiplied by the number of different bands used.

ENTRIES:

Usual awards will be issued and the standard disqualification rules will apply. Logs and entry forms are available from ARRL, 225 Main St., Newington CT 06111. All contest entries should then be returned to this same address.

WASHINGTON STATE QSO PARTY

Starts: 1600 GMT Sept 11
Ends: 2400 GMT Sept 12

Please note the time change from previous years!

The 11th annual WASH State QSO Party is sponsored by the Boeing Employees' Amateur Radio Society (BEARS) and is open to all amateurs. All bands and modes may be used. Stations may be worked once on each band and each mode for contact points and more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number, RS(T), and WASH county or state/province/country.

FREQUENCIES:

Phone: 1815, 3935, 7260, 14310, 21380, 28660.

CW: 1805, 3560, 7060, 14060, 21060, 28160.

Novice: 3735, 7125, 21150, 28160.

SCORING:

WASH stations score 1 point per QSO (including other WASH stations); all others score 2 points for each QSO with a WASH station. WASH stations multiply total contact points by the total of different states, provinces, and countries worked. All others multiply total contact points by the total of different WASH counties worked (39 max). There is an extra multiplier of 1 for each group of eight contacts with the same WASH county for non-WASH stations.

AWARDS:

Certificates will be awarded to the highest scoring stations (both single and multi-op) in each state, province, country, and WASH county. Additional certificates may be issued if warranted.

The Worked Five BEARS Award is also available to anyone working 5 club members before, during, or after

* = described in last issue

the QSO Party. All QSO Party entries will be screened by the Contest Committee for possible Worked 5 BEARS Awards. A Worked 3 BEAR Cubs Award is also available for working 3 Novice members.

ENTRIES:

Logs must show dates, times in GMT, stations worked, exchanges sent and received, bands, and modes used and scores claimed. Include check sheet for entries with more than 100 QSOs. Each entry must include a signed statement that the decision of the Contest Committee will be accepted as final. No logs can be returned. Results of the QSO party will be mailed to all entries and an SASE is NOT required. Logs must be postmarked no later than October 11, 1976 and sent to Boeing Employees' Amateur Radio Society, c/o Contest Committee, Willis D. Propst K7RSB, 18415 38th Ave. S., Seattle WASH 98188.

PENNSYLVANIA QSO PARTY

Operating Periods:
1600-0500 GMT Saturday, Sept 11
1300-2400 GMT Sunday, Sept 12

The 19th annual PA QSO Party is sponsored by the Nittany ARC and all amateurs are invited to participate. PA stations may work both in-state and out-of-state stations.

EXCHANGE:

QSO number, RS(T), and PA county or ARRL section.

FREQUENCIES:

Phone: 1815, 3980, 7280, 14315, 21380, 28560.

CW: 1810, 3550, 7050, 14050, 21050, 28050.

Novice: 3715, 7160, 21115, 281115.

Please note changes from last year's frequencies!

SCORING:

PA stations score 3 points per non-PA QSO and 1 point per PA QSO. Final score is total number of QSO points times number of ARRL sections worked (including EPA and WPA) plus a multiplier of 1 for any DX. Non-PA stations score 1 point per QSO times the number of PA counties worked (67 max). Stations may be worked once per band and mode.

AWARDS:

Certificates to section winners with 10 or more QSOs.

ENTRIES:

Logs must show dates/times in GMT, stations worked, exchanges sent/received, bands, modes, number of new section/county as worked. A summary sheet should be included indicating number of QSOs, total counties/sections, QSO points, claimed score, rig description, operating time, and any other gripes, suggestions, etc. Mail by October 15th to Douglas R. Maddox W3HDH, 1187 S. Garner St., State College PA 16801. Do not include an SASE.

YLRL HOWDY DAYS

Starts: 1800 GMT Thursday, Sept 16
Ends: 1800 GMT Saturday, Sept 18

Scores will be based on contacts with licensed women operators ONLY. All bands and modes may be used but crossband operation and net contacts are not permitted. Only one contact with each station will be counted.

SCORING:

Score 2 points per YLRL member worked and 1 point for each non-YLRL member YL worked. No multipliers!

AWARDS:

Top scoring YLRL member will receive her choice of a YLRL pin, charm, or stationery. Non-YLRL member will receive a one year membership in YLRL.

ENTRIES:

Logs should be sent to Mrs. Myrtle Cunningham WA6ISY, 1105 East Acacia Ave., El Segundo CA 90245.

VE/W CONTEST

CW
Starts: 0001 GMT Saturday, Sept 18
Ends: 0000 GMT Sunday Sept 19
Phone
Starts: 0001 GMT Sunday Sept 19
Ends: 0000 GMT Monday Sept 20

The Montreal Amateur Radio Club Inc. invites all W/K and VE/VO amateurs to participate in the 1976 VE/W contest to be held the weekend of September 18-20.

Rules for the 1976 contest include some changes from last year, and therefore should be read carefully by everyone intending to participate. These changes were incorporated at the request of many amateurs participating in last year's contest.

A 10X multiplier is continued for W/K participants in an attempt to equate U.S. and Canadian scores, thus encouraging more competition between the two areas.

Stations should look for each other in the "General" part of the phone and CW bands, and are reminded to check all bands for openings.

Log sheets, regardless of score, will be of definite interest in preparing the contest summary. It will also be of definite interest in preparing "soapbox" comments, unusual occurrences, etc.

ELIGIBILITY:

The contest is open to all licensed amateurs located in the ARRL sections listed on page 6 of any *QST*.

CLASSES OF ENTRY:

The contest is divided into two classes: CW and phone. CW and phone scores must be logged, tabulated and submitted separately.

TYPES OF ENTRY:

There are two types of entry — single operator and multi-operator. A single operator station is one manned by an individual amateur who receives no assistance from other persons during the contest, such as log keeping or spotting stations.

Stations where two or more amateurs operate a station, or where a single operator receives assistance in operating the station, must be placed in the multi-operator category.

CONTEST PERIOD:

CW Class — All CW contacts must be made during the period 0001 GMT Saturday, September 18 and 0000 Sunday, September 19. Only 18 hours total operating time may be used during this period. Times on and off the air must be shown in the log. Minimum time off period allowed is 15 minutes. Listening time must count as operating time.

Phone Class — All phone contacts must be made during the period 0001 GMT Sunday, September 19, and 0000 GM Monday, September 20. Only 18 hours total operating time may be used during this period. Times on and off the air must be shown in the log. Minimum time off period allowed is 15 minutes. Listening time must count as operating time.

BANDS:

All bands and modes for which the participating entry is licensed may be used. A station may be worked once on each band in each contest classification. The use of repeaters for contest exchanges is not permitted.

EXCHANGE:

W/Ks will work VE/VO stations and vice versa. W/K to W/K and VE/VO to VE/VO QSOs do not apply. Valid points can be scored by contacting stations not in the contest if complete exchanges are made. The exchange consists of RS or RST report, a consecutive number beginning with 100 for the first CW contact made at the beginning of the contest, and the number 200 for the first SSB contact, and the ARRL section for W/Ks and geographical areas listed below for VE/VOs.

Newfoundland	VO1	NFLD
Labrador	VO2	LAB
P.E.I.	VE1	PEI
Nova Scotia	VE1	NS
New Brunswick	VE1	NB
Quebec	VE2	QUE
Ontario	VE3	ONT
Manitoba	VE4	MAN
Saskatchewan	VE5	SASK
Alberta	VE6	ALTA
British Columbia	VE7	BC
Yukon	VE8	YUK
Northwest Territories	VE8	NWT

Example CW exchange might be "W9XXX DE VE4YYY 579-165 MAN K"; an example SSB exchange might be "VE1WWW, this is W7ZZZ. Your report 5 and 9 and 296 Oregon go ahead."

SCORING:

Each completed contact is 2 points times the number of sections worked on each band, plus a 10 times multiplier for U.S. stations participating,

RESULTS

RESULTS OF THE 1976 YLRL, YL-OM CONTEST

Overall winners:

YL – CW		OM – CW	
WA5VJW	21,532.5 points	AC4CHK	1,500 points
YV5CKR	16,669	W5WZQ	1,365
W4VQZ	13,800	W3ARK	1,282.5

YL – Phone		OM – Phone	
W7JYX	52,345	AD4JRB	2,535
W4VQZ	48,240	I0DUD	2,430
I3MWP	40,128	W4CHK	2,040

Other High Scores were:

YL – CW		YL – Phone	
K1NEI	10,295	LU1BAR/W3	21,538
WA2DMK	7,356.25	W4LYC	1,770
WA3SWU	350	WB5LMZ	6,000
WA4EPM	2,945	WA6ISY	2,450
W5QWI	3,135	K8ONV	18,176
WA6TOD	6,500	W9VNG	24
K8ONV	12,400	WA0YNC	11,115
WA0YNC	11,115	VE7DKC	2,626
VE2EDO	2,565		

OM – CW		OM – Phone	
W1PEG	875	W1PEG	80
W2RPZ	672	K2LFG	522.5
AD3RFB	238	WA3KSQ	227.5
K4IEX	800	W4KFB	625
K5RRG	797.5	WB5GRI	175
W6ZT	638	W7AHZ	165
AC7BKK	300	W9LNQ	906.25
W9LNQ	656.25	W0GNX	1,440
WA0FMD	747.5	VE2QO	61.25
VE3EMA	840		

e.g., 25 contacts in 10 sections on 21 MHz, 10 contacts in 10 sections on 14 MHz, and 20 contacts in 10 sections on 3.7 MHz = 25 + 10 + 20 = 55 contacts x 2 = 110 points x (10 + 10 + 10) 30 = 3300 points for Canada, but 3300 x 10 = 33000 for U.S. stations.

CONTEST SUBMISSION:

Log sheets and a summary sheet are required with every submission. The summary page will be submitted as the first page of each entry showing number of contacts, multipliers and total scores. Any 200 plus contact entries are also required to have check sheets (ARRL, op aid #6) for listing or awards. A separate submission for each class (CW and SSB) is mandatory. All entries must be postmarked no later than October 31, 1976, and become the property of the contest committee.

OPERATING AIDS:

Check and summary sheets are available from the VE/W Contest Committee, P.O. Box 2206, Dorval Station 780, Quebec, Canada. Include SASE (legal size), IRCs or *Canadian* stamps with your request. Official sheets are not necessary and reasonable facsimiles are acceptable. No forms will be sent unless sufficient postage accompanies your request.

AWARDS:

Plaques will be awarded to the high scoring Canadian and to the high scoring U.S. entry for both classes, CW and SSB, donated by the Montreal Amateur Radio Club. A minimum of 25 QSOs is required to qualify. Entrants operating under reciprocal licensing agreements are not eligible for plaques.

Certificates will be awarded for the high scoring stations in each section for each class and type of entry providing at least three entries in each class and type are received from each section.

DISQUALIFICATIONS:

If the claimed score of an entry is reduced by 2% or more, logs may be disqualified. Score reductions may be made for taking credit for unconfirmed QSOs and/or multipliers, duplicate contact, or other scoring discrepancies.

The ruling of the VE/W contest committee will be final in all instances of doubt.

SCANDINAVIAN ACTIVITY CONTEST

CW

Starts: 1500 GMT Saturday, Sept 18

Ends: 1800 GMT Sunday, Sept 19

Phone

Starts: 1500 GMT Saturday, Sept 25

Ends: 1800 GMT Sunday, Sept 26

Non-Scandinavian stations will try to work as many Scandinavian stations as possible. The same station may be worked once on each band during the contest. Only CW-CW and phone-phone QSOs are valid. Valid Scandinavian prefixes will be: LA, JW, JX, OH, OHØ, OX, OY, OZ, and SM/SK/SL. Use all amateur bands, 80 to 10 meters. General call will be CQ SAC for non-Scandinavian stations or CQ TEST for Scandinavian stations.

CLASSES:

Single operator, multi-operator/single transmitter, multi-operator/multi-transmitter. Club stations are in multi-operator class even if operated by a single operator. Multi-op/multi-transmitter stations should use separate series of serial numbers for each band.

EXCHANGE:

RS(T) and serial number starting with 001.

SCORING:

Score 1 point per completed QSO. Multiplier is number of Scandinavian countries per band, maximum of 10: LA — Norway, OH — Finland, OHØ — Market Reef, OY — Faroe Islands, SM/SK/SL — Sweden, JW — Swalbard, OHØ — Aland Islands, JX — Mayen Islands, OX — Greenland, OZ — Denmark.

Final score is the sum of complete QSOs multiplied by the sum of multipliers.

AWARDS:

The two highest scoring stations in all operating classes on CW and phone will receive the Contest Award in each participating country as well as in each participating USA call area. Other certificates may be awarded depending on the activity in each country or call area.

LOGS/ENTRIES:

Logs are to be filled in in the following order: date and time in GMT, station worked, sent #, received #, band, note new multiplier. Separate logs for each band are not necessary but a summary sheet showing totals of each band and final score is required. On summary sheet include: callsign, name, full address, and operating class. Separate logs are required for CW and phone. Include any comments on the summary sheet. Also, include a signed statement that you operated according to all rules and regulations and agree to the final decision of the Contest Committee. Logs must be mailed no later than October 15th to SSA Contest Manager SMØDJZ, P.O. Box 3036, S-195 03 Maersta, SWEDEN.

MARYLAND/DC QSO PARTY

Starts: 2300 GMT Saturday, Sept 18

Ends: 0100 GMT Monday, Sept 20

The 10th QSO Party is sponsored again by the Maydale ARS. The same station may be worked on each band and mode for QSO points as well as band multipliers.

EXCHANGE:

QSO number, RS(T) and QTH. MD/DC send county (Baltimore City and Washington separate). Others send ARRL section or country.

FREQUENCIES:

75 kHz from low end of CW bands on even hours, 25 kHz from top of each phone band on odd hours. Try 10 and 15 on half hours.

SCORING:

Score 2 points for each QSO. MD/DC stations multiply QSO points by number of ARRL sections and countries on each band. Others multiply QSO points by number of MD counties and independent cities (24 max) on each band.

AWARDS:

Certificates to top scorers in each ARRL section and country with 100 points minimum on each mode, to top MD scorers in each county with 1000 points minimum on each mode.

ENTRIES:

Use separate logs for each band and mode as well as a check sheet for each band and mode with over 100 contacts. Include a summary sheet showing scoring, name and address, and a signed declaration that all rules and regulations were observed. Send all entries to Maydale ARS, c/o C.E. Anderson K3JYZ, 14601 Claude Lane, Silver Spring MD 20904.

DELTA QSO PARTY

Starts: 2000 GMT Sept 25

Ends: 0200 GMT Sept 27

All amateurs are invited to participate in the 7th annual Delta QSO Party which is sponsored by the Delta Division of the ARRL. Contacts must take place during the contest period with no time or power restrictions. Any station disrupting a working Delta Div traffic net or whose log exhibits obvious irregularities will be disqualified from award consideration. General call will be "CQ DELTA QSO PARTY" on SSB and "CQ DELTA" or "CQ TEST" on CW.

EXCHANGE:

QSO number, RS(T), and QTH: ARRL section for non-Delta, county and state for Delta. Portables and mobiles may be reworked on the same band/mode if changing counties. Stations may be worked once on each band/mode otherwise. Delta Div stations may work other Delta Div stations.

FREQUENCIES:

Novice: 3725, 7125, 21125, 28125.

SSB: 3990, 7290, 14290, 21390, 28590.

CW: 3550, 7050, 14050, 21050, 28050.

SCORING:

Delta stations take number of QSOs times number of ARRL sections (75 max) worked for final score. Outside Delta Div, take number of QSOs times the number of counties worked within the Delta Div (316 max). DX stations may be worked by Delta Div stations but do not count for multipliers.

AWARDS:

Delta Achievement Award — All amateurs contacting 5 hams in each of the 4 states comprising the Division will receive this certificate. Certificates will be awarded to the 3 highest scoring stations in each state within the Delta Div; 4th and 5th will also be given if warranted. Certificates will go to the high scoring station in each ARRL section and country; 2nd and 3rd will be given if warranted. A plaque will be given to the high scoring station both inside and outside of the Division. Plaques will also be awarded to the high scoring portable and mobile stations operating within the Delta Div. A portable or mobile must be operating outside his home county to be eligible. The Lafayette ARC will sponsor the plaques.

ENTRIES:

Logs must include date/time, station worked, exchange, band, mode, and multipliers. Logs must be postmarked no later than October 21, 1976 to be eligible for award consideration. Logs will be returned if requested. Send logs to Malcolm P. Keown K5RUB, 213 Moonmist, Vicksburg MS 39180.

1976 CALIFORNIA QSO PARTY

Sponsored by the Northern California Contest Club

The 1976 California QSO Party will begin at 1800 UTC (11:00 am PDST) on Saturday, October 2, and end at 2400 UTC (5:00 pm PDST) on Sunday, October 3. Of the thirty hour period, the maximum operating time shall not exceed 24 hours. Times on/off must be clearly marked in the log. Each time off shall not be less than 15 minutes.

BANDS:

All amateur bands may be used, and stations may be worked once on phone and once on CW on each band. A California station which changes counties (i.e., a mobile or portable) is considered to be a new station and may be contacted again on each band and mode.

SCORING:

California stations will transmit consecutive QSO numbers and county. Non-California stations will send consecutive QSO numbers and state, Canadian province, or country. California stations may work each other, but contacts between stations outside of California have no contest value. Each complete QSO shall count two points; no credit is allowed for partial contacts. The multiplier for California stations shall be the number of different states plus Canadian call districts (VE/VO 1 — 8, maximum of 8). California stations may count the state of California as one multiplier. Also, DX may be worked for QSO points, but does not count for multipliers. Non-California stations will use as their multiplier the number of different California counties worked (58 maximum). The final score equals total QSO points times the multiplier.

FREQUENCIES:

CW: 1805, 3560, 7060, 14060, 21060, 28060.

SSB: 1815, 3895, 7230, 14280, 21355, 28560.

Novice: 3725, 7125, 21125, 28125.

Try 10 meters on the hour and 15 meters on the half hour between 1800 and 2200 UTC.

LOGS:

Log information should include date, time, band, mode, callsigns

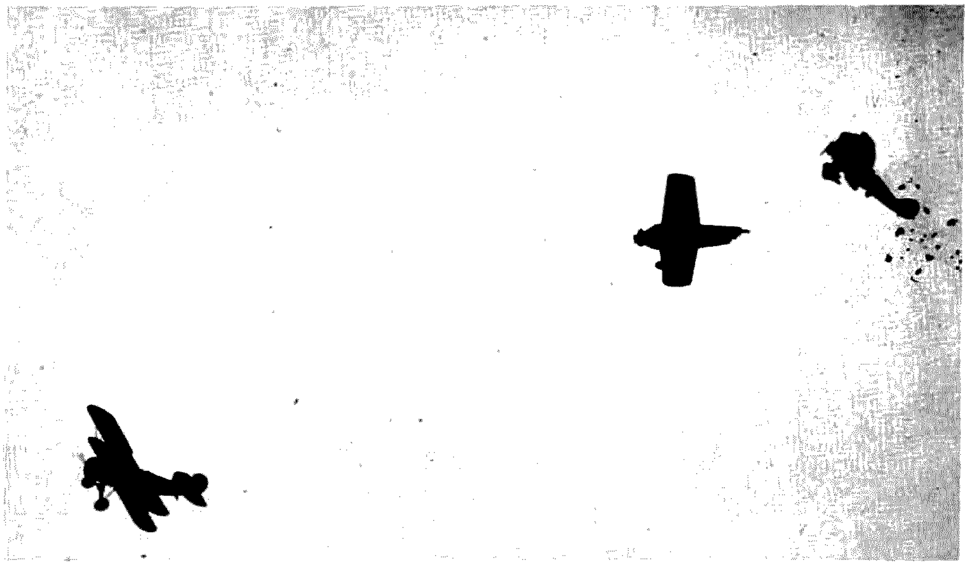
TRAGEDY AT TRENTON

In the early 1930s a popular way for various organizations, such as American Legion posts, service clubs, etc., to raise funds was to sponsor so-called "Air Meets" or "Air Races" at their local airports. One of these was a two day affair at Trenton's Mercer Airport on October 19th and 20th, 1930. It carried the prepossessing title of "All Eastern States Air Meet." I was serving as Judge and Starter in the closing event of the meet, a 25 mile race over a triangular closed course with one pylon on the airport field.

Five planes were lined up ready to start when Mrs. Opal Kunz landed and asked to compete in the race. I asked the pilots of the other five planes if they had any objection to her last minute entry and they all agreed to let her compete.

So I started them off at 50 second intervals and went over to the home pylon to make sure that no one was cutting any corners there. On the last lap three ships were bunched on their approach to my pylon. George Zinn in his Taper Wing Waco was low and on the inside, Mrs. Kunz a little ahead of him and on the outside, and Dick Mackie in his Cessna flying a high, safe race about 150 feet above Mrs. Kunz. Just as they got to the pylon, Mrs. Kunz suddenly cut around directly in front of George, which forced him to pull up sharply to avoid hitting the Kunz machine. Just at that moment, however, Mackie was just above. Zinn's Waco collided with the Cessna and cut its whole tail off. Zinn's Waco lost its flying speed and dove in about 100 feet from where I was standing. Mackie's Cessna seemed to fly along straight and level for a few seconds, but when he throttled back it went straight in. Both were killed instantly. From left to right in the photo are the Kunz plane that cut in front of Zinn, the Cessna with its tail cut off, and Zinn's Waco, with pieces of the Cessna's tail over Zinn's engine and, in pieces, behind (photo by S. Dennis Welsh). Pieces were also falling all around me. I'll never forget it.



LUDINGTON LINE, ETC.

In early 1931, the New Jersey legislature passed a bill setting up a State Aviation Commission consisting of a Director and five Commissioners. I was one of the five. This Commission had jurisdiction over all aviation activities in the State. Meetings were twice a month. You got a nice commission signed by the Governor, a gold badge of authority, and special auto license plates. Actually there wasn't much for a State Aviation Commission to do, since the Aeronautics Branch of the U.S. Department of Commerce already had jurisdiction over most aviation activities. I resigned my commission in December, 1933, when I changed my official residence to New York State. Just wanted to let you know that I carried a badge for a while.

During the spring and summer of 1931, Gene Vidal, Paul Collins and Amelia Earhart were quite busy getting the Ludington Line ready to start operations. The idea was to furnish a frequent, low fare service between cities on a highly traveled route — in this case, between New York, Philadelphia and Washington. The Ludington brothers furnished the bucks and the "know who," Vidal and Collins, the "know how," and Amelia, the visibility. The original officer lineup was as follows: Chairman of the Board — Townsend Ludington; President — Nicholas Ludington; Executive V.P. — Gene Vidal; V.P. Operations — Paul Collins; V.P. Public Relations — Amelia Earhart; Equipment — 12 Stinson 10 passenger trimotors.

Their "Every Hour on the Hour" service from 7 am to 5 pm, to and from New York and Washington, started Sept. 1, 1930. In the first 14 months of its operations, Ludington Lines carried some 85,000 passengers; in 1931, it carried one fourth of the total passengers of all other airlines in the United States.

In the spring of 1931, Nicholas Ludington developed a case of tuberculosis and had to retire to his house in Santa Barbara, California, for a year in bed. That left his brother, Townsend, who was in very poor health, to direct their investment in the airline. So they hired Jim Eaton from Pan American and installed him as President in the fall of 1931. Eaton then tapped me for Assistant to the President and General Traffic Manager of the line. I was glad to shift from the airport to the airline.

The Stinsons had seats for ten passengers and a crew of one — the pilot. The only radio aboard was an airway radio beacon receiver. As an economy measure, the Stinson's center section 20 gallon tank was filled with aviation gasoline, which was used for take-offs. After climbing to about 1000 feet, the pilot switched to the cheaper automobile fuel in the other tanks. This worked very nicely during the winter of 1930-31, but along in April we had a day of unseasonably hot and humid weather. That day Ludington had five forced landings before they knew what had happend. No damage except for some "seized up" engines and a few scared passengers. It seems that they were a bit late in changing from winter auto gas to the summer type.

A more serious thing happened in November, 1931. In the middle of September, the line introduced a new high speed nonstop service of two round trips a day between Washington and Newark Airport, using a new Lockheed Orion. One of these schedules departed Newark at 4:40 pm, and by the time it reached Central Airport (in mid-November) it was dark. On this flight, Capt. Floyd Cox was on his final approach over a golf course when he "ran out of air" and the unforgiving Orion did half a turn of a spin before hitting the ground. Four passengers, the pilot and the Orion became statistics. Townsend Ludington wanted to shut the airline down the next morning. It was the only accident the line had in its two and a half years of operation.

In March, 1932, our airline headquarters was moved from Philadelphia to the Washington-Hoover Airport, so we rented an apartment out on Conn. Ave. By midsummer, 1932, the "Depression" was being felt by everyone. More and more people were finding air travel, or for that matter, travel of any kind, more than they could afford. So our passenger revenue declined somewhat in spite of the many remedies we tried. Then came the Presidential election of 1932 when FDR swept the country except for Vermont and Maine. As a sort of last resort we made a good try at selling the Post Office Department on putting mail on our frequent service. All to no avail. So Nick Ludington

Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

Where were we in the July issue, you ask? Actually, with the July column usually being written in late April and our having to be out of town at the same time, we decided that it would be better to take a vacation for a month than to just write a piece to fill space. Between New York and Dayton we now have a lot to report, and so, on to that wonderful world we love and call amateur radio.

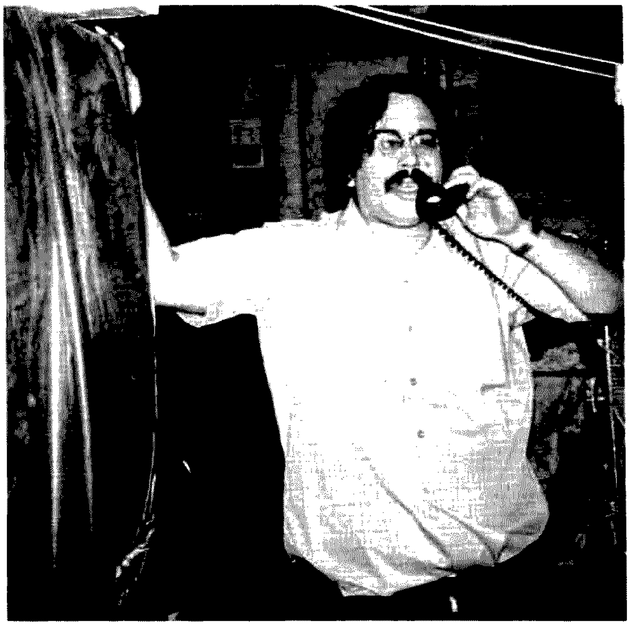
I am beginning to get the impression that I may have opened another can of worms; at least that's the way the mail is running that I am getting about my June "special" on total voluntary coordination (see June 1976 p. 8) and the idea of both offering and/or involving all VHF/UHF oriented amateurs in such a program. There were two specific reasons for my writing that article, plus a third which while left basically unstated is no less important.

First, I, along with many other concerned amateurs, feel that while it would be very nice for the ARRL to officially recognize the work *now being done* by those involved in repeater coordination, it is not for that organization to now, after the majority of the work has already been accomplished, come in and tell the amateur community that they will appoint someone in each area to do this work either in concert with already existing efforts, or by replacing same. In my opinion, the reason that the majority of coordination efforts have been so successful has been that in most cases the people doing the coordinating work have been asked to take on this job by their peers, their fellow amateurs. To carry this one step further, if the League must get itself involved in this work, then it has a sincere obligation to all amateurs, *both League members and non-members alike*, to elect such people in a like manner to the way that League Directors are elected, since any persons elected to this type of position will hold a heck of a lot of power in their hands. I for one would want to be in a position to cast my ballot and help elect such a person based upon what I know about such a person's qualifications, rather than having such "rammed down my throat." Based upon this, I must for now continue to oppose the concept of a League appointed coordinator until such time as the ARRL publically clarifies exactly how such a person will be chosen and by whom, as well as specifically spelling out what his duties will be in relation to already existing coordinating bodies. How will such a person relate to already operational coordinating efforts and, most important, should a disagreement arise between an existing coordinating body and a League coordinator, whose word will be final? At this moment, June 1, 1976, these are questions yet unanswered. I sincerely hope that before you read this, the answers will be in all our hands.

Secondly, today's existing coordinating efforts grew up as a need for "government by crisis." FM and repeaters grew up fast, almost too fast in some places. In a matter of but a year or so, some cities found repeaters sitting on repeaters, repeaters encroaching on area simplex channels, and tempers rising. Order was needed from the chaos and out of this need was born the repeater coordinating council. Now while councils are not perfect entities, at least they are representative of the views and voices of the majority of the FMers in any given administration area. Sure, they make mistakes, but because of the very nature that they are entities of more than one individual, they are less likely to repeat such mistakes. By and large you have to admit that most have done a pretty good job in making things work well. Now with the advent of the multi-mode VHF transceiver — you know, that cute package that lets you run CW, AM, FM, SSB plus other various types of emissions from but one radio — there is a growing trend toward operation on these other modes, especially SSB for "DXing." One of the things that I learned I was right about is that in some areas, two meter SSB is growing so fast that local amateurs are making efforts to set aside specific frequencies for such things as DX calling, local rag-chew calling, tune-up, etc. Sound familiar? Even more interesting, the term being given to these frequencies is "channels." If this is then to be a sign of things to come, do we wait once more until we again need "government by crisis," or do we act now and offer the experience we have garnered from repeater coordination to those expanding into new facets of VHF communication to help them avoid any future crisis? At the moment, one might rightly state that, due to the limited amount of activity coupled with the current high price of such equipment, no such need exists. But, many new amateurs are coming soon into our ranks as a result of the new ARRL training program (many I suspect with eventual VHF interest), and as technology progresses and the market increases, prices may come down on equipment such as this (may I cite the electronic calculator, the digital watch and the under $100 CB radio as examples of what advanced technology coupled with good marketing practice have done for consumer prices) and bring more amateurs to this and other modes. I for one do not believe in forcing any amateur to do something contrary to his or her belief. However, by the same token, I do feel that if the interest is there, then these and all people have a right to have their views aired. Therefore, if amateurs involved in other modes are interested in involving themselves in some form of coordinated band plan, to formulate among themselves a plan for the future that will insure the sanctity of all amateurs, I for one do not feel that they should be relegated to the sidelines just because they do not own a repeater (as you know, "repeaters are the in thing these days"). Yes, repeaters are "in" right now, but in 10 years, what will be "in" then? I for one am glad to see the advent of the multi-mode transceiver for VHF. Slowly but surely it is taking a bit of the pressure off many very crowded VHF repeaters and at the same time adding diversity to the operating habits of many amateurs. Repeaters are great fun, true, but many VHFers fail to realize that there is a whole world below 146 MHz, and that world is an entity unto itself.

As I said, there are three reasons, and the third is possibly the most important of all. If we are to grow, we must develop lines of communication

All it takes to work EME is a station like that of Bruce Sternstein K2RTH and a little patience.



Remember Larry WA2INM who used to write for 73? He is alive, well, on 2 FM, and a champion Siamese cat breeder these days.

that extend far beyond the coverage area of our favorite repeater. We must learn to interact with people whose interests are different than ours and realize that while FM and repeaters are nice, they are but one facet of the overall VHF/UHF picture. If you have never tried working a distant station on 6 meter E or F2, you are missing something. If you have never sat in a round table on two meter AM and been able to talk for 5 or 10 minutes without worrying about timers cutting you off, then you have bypassed a good part of the show. There are people out there, potential friends if you want them. It only takes tuning below 146 MHz to find them.

Now to Southern California and back to that wonderful world of amateur radio. Have you listened to six meters down at the low end lately? Around this part of the country, the DX seems to have started rolling in like in the old days. Most of it is single or double hop E, but as the season progresses there should be some F2 and that will really make it wild. Most of the activity centers around the area of 50.1 to 50.2 SSB, but there is some good stuff on AM as well from around 50.25 up to about .5 or .6. However, the analogy of it being like the "old days" is really not that correct. First, the old days for me were the late 50's and early 60's, but 3000 miles to the east. Therefore, comparisons are a bit hard to make and/or justify. I can tell you that with a ¼ wave ground plane atop the building I am working a bit of the current DX. Since I no longer have my old Swan 250 nor the funds to replace it, I am stuck on medium power AM and CW. For those interested, the six meter station here is nothing more than a Hammarlund HQ110A with an Ameco Nuvistor preamp ahead of it and a choice between an AMECO TX-62 or Knight T-150 transmitter, dependent upon whether I am working the station AM or CW. General band monitoring is done with an old Gonset Comm II. Of note is the fact that most AM users here in Southern California are omnidirectional and vertically polarized, while SSB and CW are horizontal. FM is vertical, with the output of the WA6UJS repeater, 52.525, being the local FM calling channel. Activity here on 6 seems to be on the rise on all modes other than CW, with the majority of CW that I hear being of the MCW variety for code practice.

When you reach a point of "repeater media overload" or more plainly said, the sound of another squelch tale or reset beep will drive you up a wall, six is a real nice place to escape to and lately it seems that more and more people are dusting off their old communicators and 99ers to join the fun. The local people I run into on six are just great, and the best part is that you cannot time out a simplex QSO. After having been wrapped up in repeaters and FM only for a good number of years, getting back on six and back to basics is a real treat. Don't believe me; try it yourself and see.

Last month we mentioned that we would be heading to New York and then on to Dayton for the Hamvention and the festivities there. Next month we will tell you about our impression of the Hamvention, but for now let's all get on board that red and white TWA 707 and go east to the megalopolis of New York. The flight itself must have been good. I am assuming this since I literally slept from Los Angeles to NYC. Sharon told me that around 3 am (we flew the red-eye) we hit a bit of turbulence, but I managed to sleep right through it. I awoke to the sight of the sun coming up over the Atlantic and quickly recorded this event on super 8 movie film. We ate a quick breakfast and then landed at good old JFK International. Right on the numbers for you fellow pilot types.

Sharon's mom and dad were there to meet us and after the customary welcomes and obtaining our baggage (very quickly — one of the advantages of night flying on a medium-sized aircraft), we exited the terminal to be greeted by a blast of 78 degree hot sticky air and the sound of two taxi drivers arguing about who was first in line to pick up a fare. Ah . . . yes, we were in New York! 6:30 am.

The thing that I wondered about most was how well was the right side up split-split repeater plan that they follow working in comparison to the inverted plan that we here in Southern California use. I unpacked my stock FMH that I had equipped with crystals for .25/.85 (WR2ADM) and .13/.73 (WR2AAA) to see what I could hear and to see who was around. It was now about 11 am Sunday morning. There was a QSO on ADM and I recognized the voices and callsigns, so I tried to break. No luck. I figured that the transmit rock was probably off frequency since I did not have the time to net any crystals before the trip. I flipped over to AAA, but heard nothing. Oh well, will have to run into Brooklyn and use INM's counter later. On .52 simplex (in NYC simplex is called "direct") I managed to get a QSO going with one of the locals; we compared notes about two meter activity for about an hour with a number of other stations breaking in and out of the QSO during that time. Soon the friends and relatives started to arrive, including our 6 month old new nephew, Scott, along with his parents (Sharon's sister and brother-in-law), and this signaled an end to my hamming for the day. It was party time and besides, meeting little Scott was the prime reason for the trip. Away with the HT and out with the cameras.

Around four the next afternoon, after visiting my dad and making his Zenith color TV have color again, I stopped over to see Larry Levy WA2INM. You may remember Larry as he was one of *73*'s first technical writers in the 60's. After a cold one to wash away the New York City air pollution, which in my mind is far worse smelling than what LA is famed for, we adjourned to his basement

A sign of things to come? ICOM West representative shows new IC-202 2m SSB portable at SAROC '76. Is it the thing that may replace today's FM hand-held? Who knows?

workshop to count Hz's. Hmmmmm . . . what's this? Seems as if both my .13 and .25 transmit crystals were stone dead. A few more tests showed that my .73 receive had met the same premature fate. Since FMH rocks are a scarce commodity in NYC, Larry graciously offered to loan me his TR-22. Again, this was a stock unmodified TR-22 purchased in 1971. I stress the point unmodified since such a radio will perform without any problem in and around LA under the inverted split plan. To say that the early TR-22s were somewhat broad in the selectivity department, especially by today's standards, would be a fair assumption. This radio was equipped with four repeater pairs plus .52 and .94 simplex and was set up in my father-in-law's Chrysler using a borrowed ¼ wave gutter clip supplied by "Uncle Lou" K2VMR.

No problem on .25/.85. We were staying with Sharon's mom and dad in Valley Stream and were but a stone's throw from the location of WR6ADM. The welcome we were given on that repeater was the warmest we found anywhere on our trip. ADM is sponsored by LIMARC, the Long Island Mobile Amateur Radio Club, and being with LIMARC people is to me very much like being home on WR6ABB with PARC people. In fact, while it has received no publicity to date, last January LIMARC and PARC became sister clubs on an informal basis as a gesture of goodwill between amateurs separated by the miles as part of our nation's bicentennial celebration. In fact, I believe this is probably the first formal public announcement of this happening. The two clubs call it "Hands Across A Nation in '76"; however, I was asked while in NYC to bring word back to PARC that LIMARC would like to make this informal tie permanent. I suspect it will be.

Slipping over to .28/.88, I accessed the Staten Island repeater and ran smack dab into a long time friend of mine Andy Feldman WB2FXN. My, how time flies; the last time I had spoken with Andy was just after he and Eileen had gotten married. Now they have a kid of their own and have moved to a new QTH over in Jersey. I listened for a while after signing with Andy and noted that something on an adjacent channel was being heard by the TR-22. Never did identify it though. On .13/.73 I found the worst adjacent channel problem noted. A repeater in Selden, Long Island 15 kHz away was giving AAA a good run for its capture money. AAA, the old WA2SUR system, is located in lower Manhattan and previously I had never heard any problem using my own TR-22, which had come from the same lot number as Larry's. The people on that Selden repeater seemed to be such a nice bunch that I really wished I had some rocks or a synthesized radio with me so that I could have met them. Think I really missed something good. I was not able to either access or hear the Greenbrook, New Jersey repeater on .34/.94, though in the past I had been able to at least hear it in Valley Stream. Later I was told that it had gone "PL" and activity on it was low. This report was never confirmed. I did, however, hear

some .94 simplex activity both on Long Island and while mobile in Brooklyn; I had a number of good QSOs with some old friends. I do think in retrospect that the WA6 callsign and the 10 codes that I have become used to using out here did shake up a number of people.

Anyhow, if I were to judge solely by what I heard on .73 with a five year old radio, I would not be making a really fair analysis. I can tell you that the stock TR-22 that I have here now (that was also purchased in or around 1971) works flawlessly in LA using the inverted split-split plan. However, I would really like someday to see someone take a good synthesized "amateur type" popular radio such as the Icom 230, or the KDK, or a Clegg FM-DX, and channel by channel evaluate both the right side up and the inverted split-split plans. It would require an amateur who happens to own such a radio with both a fat wallet to cover expenses and about a three week vacation. If I had the bread, I probably would make the time, but alas, in my present financial situation that cannot be. In reality though, such a comparison done in the major high activity areas such as NYC and LA where split-split systems exist is the only way we will ever know which method is best. I can tell you what I found, and I can tell you of the success we have had out here with the inverted splits, but until the time that such a channel by channel comparison is actually made, and made from a user standpoint with a fairly modern day user type radio, it is unfair to make any final decisions or recommendations. Any takers out there for such a project? I guarantee to publish the results. Perhaps this is another good reason for the establishment of a national coordinating council that is technologically and financially able to undertake such a research project.

Two of the people that we were happiest to see were Lou Belsky K2VMR and his lovely wife Linda. It was Lou's guidance as trustee of my old WA2ZWP, now WR2ACV, repeater that brought it back to life and built it into one of the most popular and populous open systems in New York. I discussed doing an article with him about our cross country trip in 1970 just at the time that repeaters were starting to take hold but six meter SSB was still king. From that discussion came the idea for a two or three part article you will be seeing in the near future titled "Lou, Bugsy and Me" or "Can a VW Bug Really Go 3000 Miles Between Gas Stops?" Anyhow, being able to spend time with Lou and Lin were very happy moments for Sharon and myself. Currently, Lou's big amateur radio project is putting together the Amateur Radio Communication Effort for the annual NYC Salute to Israel Parade up Fifth Avenue in June — quite a monumental task in itself.

We also got our first exposure to the art of EME or moonbounce communication thanks to Bruce Sternstein K2RTH. Bruce just happens to live directly across the street from Lou and Lin in Franklin Square, LI, and his antenna array is a bit hard to miss. We meandered across the street to Bruce's place and found out first hand what EME is all about and were thoroughly impressed. As soon as I have my own home, that's an art form I personally want to involve myself in. EME is not just another way to use amateur radio; the skill required to be really successful at it places EME in the art form class.

We had a chance to talk with Abe Schwartz WB2PQR about a project that he is working toward: a user programmable repeater using a microprocessor. The idea is to program specific needs of a given user into the microprocessor, assign each user a specific identity code and have the user punch up his code to have his specific needs performed automatically. With the amount of information that can be stored and recalled at will, it would be possible to perform tasks such as transferring the system to a directional antenna that would automatically adjust to a predetermined direction, store telephone numbers for autopatch service, and a myriad of other things. While strictly in the planning stage right now, Abe hopes to make the thing a reality in the not too distant future, and I got him to agree to drop me a line from time to time and keep me informed of his progress. The concept, if feasible, really interests me and I suspect it might interest you as well.

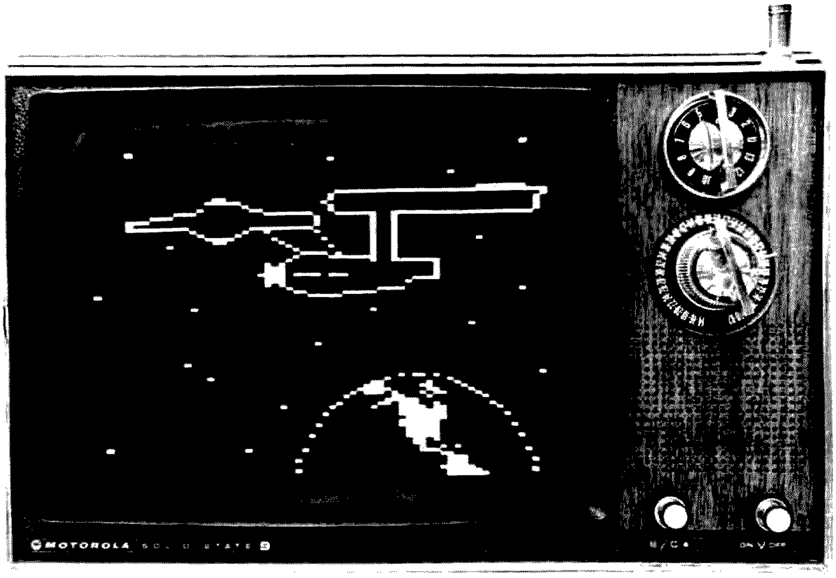
Southland Hams Win One: California Decides Not To Raise Cost of Ham Plates

Sometimes a letter writing campaign coupled with the proper form of education can win out, as was shown recently in the state of California. For many years only a nominal $3 fee was necessary in addition to the normal license plate fee to obtain amateur radio callsign plates. Then recently a re-evaluation was undertaken by the state that would have meant a reclassification of amateur callsign plates to the status of what is termed "vanity plates," i.e., personalized license plates of one form or another. This would have meant a significant increase in both the cost of initially obtaining such plates and in the cost of yearly renewal.

Rather than "flying off the handle," amateurs in California initiated a letter writing campaign specifically aimed at educating the state legislature as to the important part that the state's amateur radio community plays in regard to both public service and as a ready source of trained volunteer communications personnel in case of disaster. It was pointed out that rather than being simply a sign of one's vanity, the amateur callsign appearing on a license plate is an easily identifiable method of determining who the aforementioned emergency communicators are should ever the need arise.

As a result of this effort, the Honorable Michael Wornum, Assemblyman from the Ninth Assembly District and Chairman of the Committee reviewing the standards for issuance of automobile license plates, has amended this bill (California Assembly Bill 4271) so as to exclude amateur radio callsign plates from any increased fees. We at *73* feel that he deserves a thank you for his action on behalf of the California amateur radio community. It is apparent that Assemblyman Wornum is a public servant who listens to his constituency.

New Products



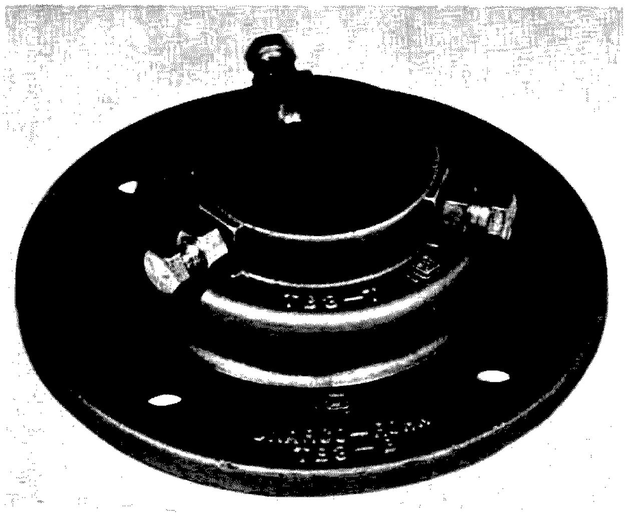
LOW COST GRAPHICS TERMINAL KIT

Southwest Technical's GT-61 Graphics Terminal kit is a low cost graphics unit designed for hobbyists or budget-minded commercial applications. The 9½" x 13" PC board contains all the electronics necessary to display an array of cells 64 wide by 96 high on a standard video monitor or modified television set. The graphics terminal contains its own 6144 bit static memory and thus may be driven by any computer system having a TTL compatible 8 bit parallel interface. The unit is available in kit form only and is sold less power supply, chassis, and monitor for $98.50 postpaid in the US. Delivery is 30 days. Southwest Technical Products Corporation, 219 W. Rhapsody, San Antonio TX 78216, (512) 344-0241.

B&K-PRECISION INTRODUCES NEW LOW COST 3½ DIGIT MULTIMETER

The Model 283, a new 3½ digit multimeter priced at $170, has been announced by B&K-PRECISION, Dynascan Corporation.

The Model 283 uses high intensity, high reliability LED displays, 0.41" high, that can be easily read in brightly lit rooms at a distance of at least six feet, according to the manufacturers. It measures dc volts, ac volts, dc current, ac current and resistance. A special low voltage circuit permits measuring resistance of tran-



sistor-shunted resistors.

The Model 283 has 100% overrange capability on four ranges, so that one can read to 199.9 on a scale that is normally set for 100.0 maximum. Out-of-range is indicated by a flashing digit and three zeros. All readings have an automatically positioned decimal point.

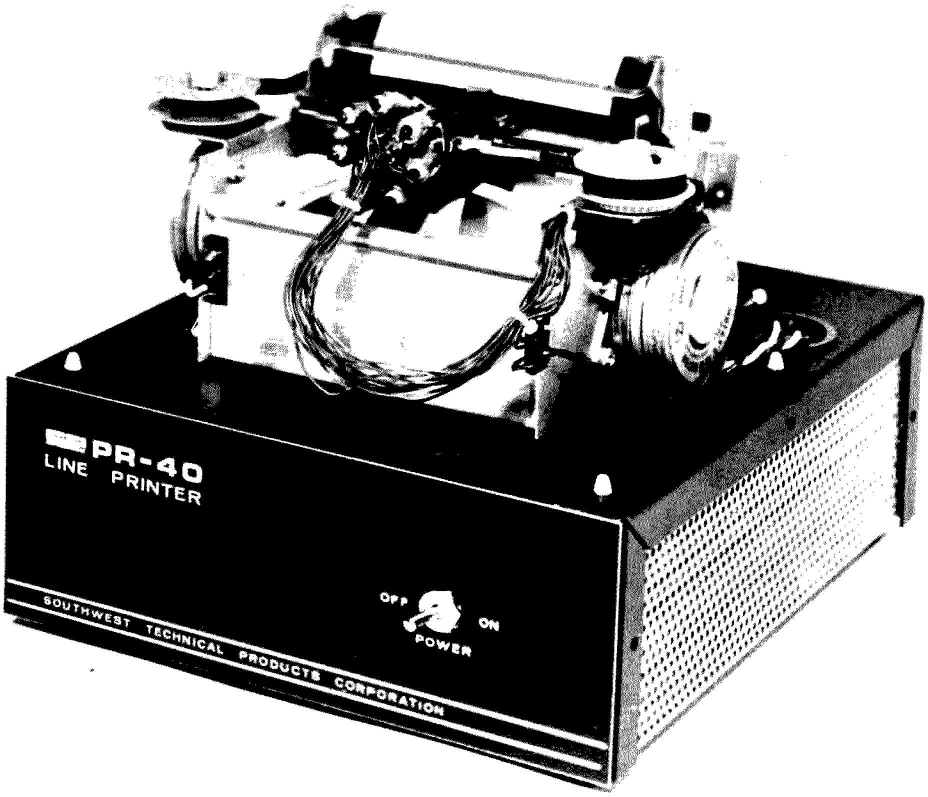
There are 4 dc voltage ranges, with ±0.5% accuracy on the 1.000, 10.00 and 100.0 ranges and ±1.0% on the 1000 V range. Polarity change is automatic. Four ac voltage ranges have ±1.0% accuracy on 1.000, 10.00 and 1000.0 ranges and 1.5% accuracy on the 1000 V range. There are four ac current and four dc current ranges (±0.1000, 10.00, 100.0 mA) with the similar accuracies. The six resistance ranges, 100 Ohms, 1k, 10k, 100k, 1000k, and 10 megohms, have ±1% accuracy, except top range, which is ±2%. Input impedance is 10 megohms on all voltage ranges.

Overload protection is provided, up to 1000 V on the Ohms, 1500 V on the voltage ranges, and 3 A on current shunts.

An optional battery pack provides 8 hours operation on an overnight charging. Batteries also charge when the Model 283 is used on a 110 V ac line.

The B&K-PRECISION multimeter weighs 3 pounds and measures only 9 x 7 x 3.6 inches. With battery pack, its weight is 6 pounds. The Model 283 and accessories are available from B&K-PRECISION distributors.

For additional information, contact Myron Bond, B&K-PRECISION, Dynascan Corporation, 6460 W. Cortland, Chicago IL 60625, (312)-889-9087.



NEW THRUST BEARING

Unarco-Rohn, Division of Unarco Industries, Inc., Peoria, Illinois, has just introduced a new thrust bearing (TB-3) for mounting antennas that is superior to anything on the market today. It is of heat-treated cast aluminum, for extra strength. The bearing incorporates 30 stainless steel ball bearings in a race that is protected from the elements, permitting freer movement at all times. Three lock nuts fasten the antenna mast securely in position. This relieves the weight of the antenna on the rotor, and at the same time allows an exceptionally free turning movement.

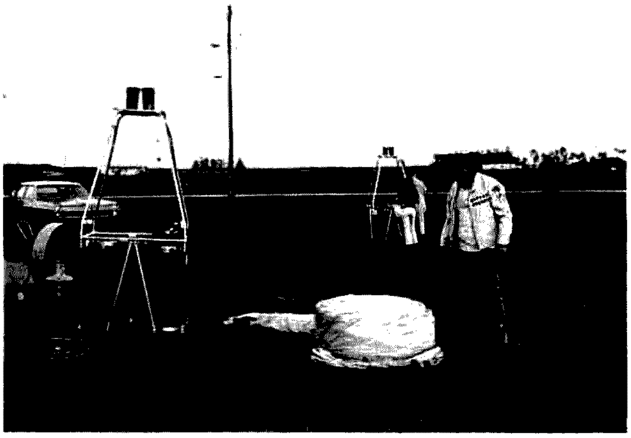
Unarco-Rohn is one of the country's leading integrated tower manufacturers. Services include tower manufacturing, engineering, fabrication, in-house galvanizing, site construction and supervision.

LOW COST ALPHANUMERIC PRINTER KIT

Southwest Technical's PR-40 Alphanumeric Printer Kit is a 5X7 dot matrix impact printer similar in operation to the well known Centronics printers. It prints the 64 character upper case ASCII set with 40 characters/line at a print rate of 75 lines/minute on standard 3-7/8" wide rolls of adding machine paper. One complete line is printed at a time from an internal forty character line buffer memory. Printing takes place either on the receipt of a carriage return or automatically whenever the line buffer memory is filled.

The printer is available in kit form only and includes the assembled print mechanism, chassis, circuit boards, components, 120/240 V ac – 50/60 Hz power supply, assembly instructions, one ribbon and one roll of paper. It sells for $250.00 ppd. in the US and delivery is 30 days.

Wayne Green W2NSD/1



Captain Crunch gets ready to unwrap his balloon. It's in a long thin bag for protection. At the left is the gondola, which breaks down to two parts for hauling around ... the gasoline-powered fan for starting the balloon ... and a spare propane tank. In the background, the second balloon for the First Ham Radio Two Meter FM Two-Way Balloon Contact is being assembled. This is the balloon in which Wayne will go up, manned by John Mickel.

Balloon to Balloon!

--another 73 first

Ed Doll W4KLM helps Will Thrasher W4SAC (Captain Crunch) with the balloon, while Bill Otting and Walt Farley K4QE pull the sleeve off the balloon.

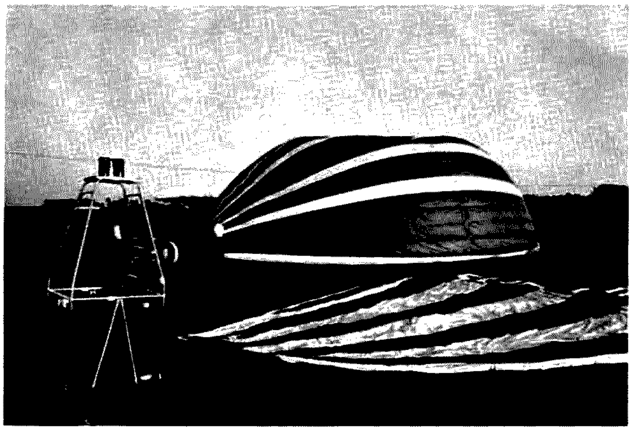
Laura Thrasher (ex-KN3DHI) fastens wires from balloon to gondola while K4QE holds balloon.

Early on the morning of May 18th, two giant balloons rose from the outskirts of Homestead, Florida, lifting two radio amateurs into the skies so that they could establish a new first ... aerostat mobile amateur to aerostat mobile amateur two-way communication.

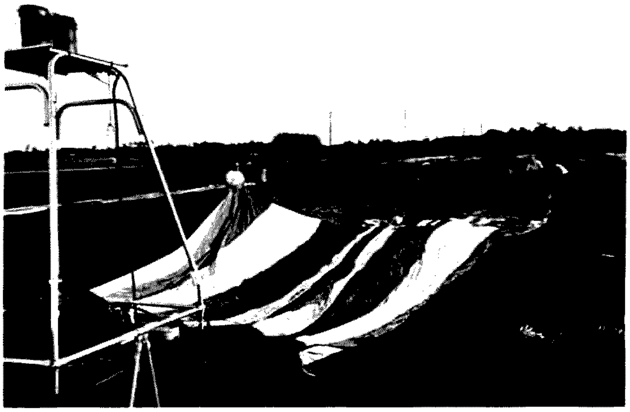
It all started a few weeks earlier when a letter from Will Thrasher W4SAC (Captain Crunch) arrived at the *73* HQ in Peterborough suggesting the possibility of a new first for amateur radio ... communications between balloons. Why not! I called Crunch and asked when I should be down for the event ... cameras and courage in hand.

On the evening of the 17th Sherry Smythe and I headed for Miami, armed with cameras, lenses, HTs, and a CB rig for the rented car. The CB rig helped us to keep track of traffic on the hour

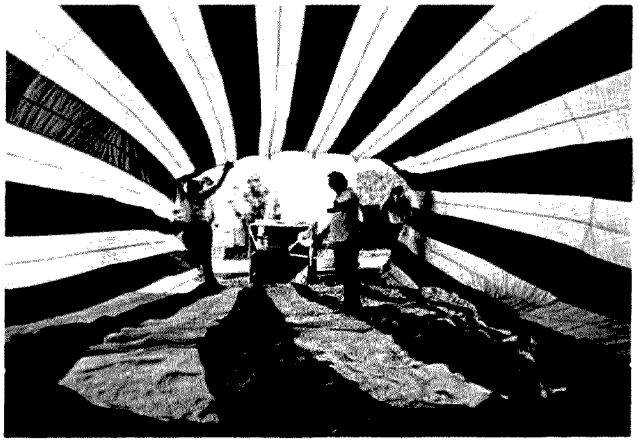
Wayne holds balloon envelope while Will pulls off the sleeve.



A small gasoline engine-powered fan is used to start inflation of the balloon.



Balloon envelope is spread out and ready to be inflated.



How the balloon looks from inside . . . W4SAC on the right, K4QE on the left.

drive to Homestead . . . and to find the motel when we got there.

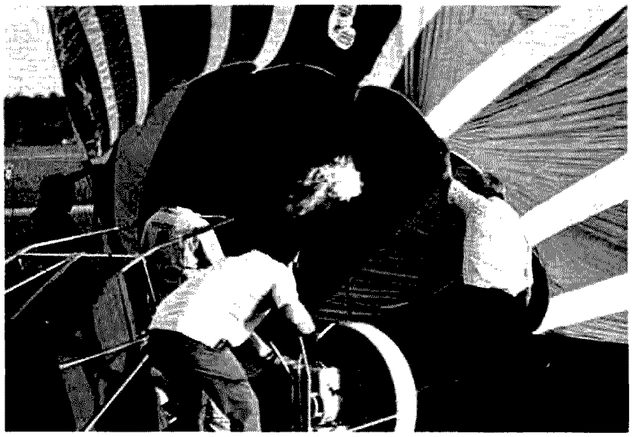
We all assembled at Captain Crunch's home the next morning a little after 6:00 am. Present were Will's wife Laura (KN3DHI), the first licensed lady balloonist in Florida . . . Walt Farley K4QE . . . Ed Doll W4KLM (retired from AT&T) . . . Captain Crunch (the second licensed balloonist in Florida) . . . John Mickel, a Florida smokey with a CB handle of Officer Friendly and a car license of FUZZ. John was taught ballooning by Will . . . and he, in turn, taught Laura. John's chase car driver was Nancy Fortier, a Delta Airlines stewardess, who is working on her balloon license. Bill Otting, Will's maintenance man, also helped get the balloons ready.

The balloons were packed in very large hassock-type bags. Once out of the bag and stretched out on the grass, they were amazingly big . . . about 70 feet long. It took three people to pull the protective sheath off the multicolored nylon material. The gondolas were quickly assembled, despite the multitudes of gnats, which were almost thick enough to drive off the mosquitos . . . but not quite. The two propane tanks were put into each gondola and strapped into place, with a pipe going to the burner located just below the open bottom of the envelope.

A gasoline-powered fan was set up to blow air into the envelopes and they quickly billowed out . . . with the help of my running around inside one pushing the material out to catch the air. Once the envelope was fairly full of air from the fan, the propane flames were turned on and shot into the envelope. With this the balloon soon righted itself and had to be held down, while we waited for the second balloon to be blown up and heated.

Soon we were ready to go. I stopped taking pictures of the preparations, gave one HT to Sherry for Will to use . . . she was going up with him . . . gave one to W4KLM to coordinate the ground support (they had to follow us as we floated along so they could bring the balloon back after it landed). Sherry also had a camera. John had his balloon about ready to take off so I hopped aboard, camera in one hand, lenses in my pockets, HT in the other hand, and trying to hold onto the gondola with an elbow as John turned on the propane. The air in the balloon has to be about 100° hotter than outside to get enough lift. It's a little scary with the flames shooting five or six feet up into the nylon balloon, roaring so you can't talk.

We lifted off at 7:22 am, just as smooth as you could ask. John said not to worry about the trees we were dragging through . . . so I didn't . . . it was just the top branches anyway. Soon we were several hundred feet up, with Crunch's balloon just a short way behind us. We'd go up and up . . . then start to settle back down again. As we came down John would give a blast of the propane and we'd slow down . . . then go back



Once the envelope is inflated, the air has to be heated. On the left is Nancy Fortier, who did the chase car routine for Wayne's balloon.

up again . . . bobbing across the landscape.

We soon had our two-way amateur radio contact in the bag . . . 146.52 MHz FM . . . and two-way with the ground to boot. Once that was done, I switched to some of the nearby repeaters and made a few contacts via them as a bonus.

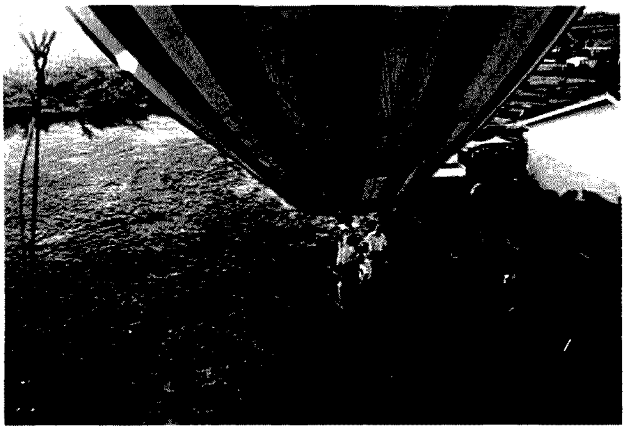
On one of the descents we came down toward a field where a bunch of women were picking okra. We yelled hello to them and arranged to come down close enough so that they could throw up an okra to us. It was a fairly open field with a road leading into it, so Crunch decided to end his flight there. He touched down gently and that was that. John and I went on a few miles further, with Nancy following in the FUZZ car. We eventually spotted a nice clear field ahead and plopped quietly into the middle of an exercise ring for horses.

Once down you have to collapse the envelope as quickly as you can so it won't be caught in a sudden breeze and drag you. We took our time . . . gave the balloon a little blast to make it lighter and walked it a couple hundred feet over to the road to deflate it there. You pull a ring and that opens up the whole top of the balloon, letting the hot air out.

The only damage done was when a propane bottle was dropped on the instrument panel as the gondola was being packed for return home. The instruments are an altimeter, a rate of climb indicator, a temperature gauge, and a watch. The thermometer got it good from the propane tank and needed at least a new cover.

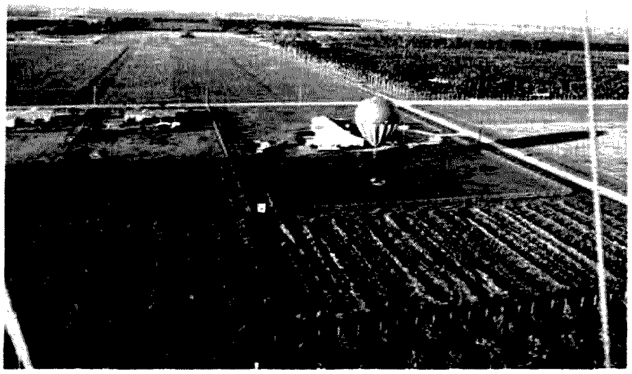
Back at Crunch's home we played a tape of the morning's events and ate doughnuts. Laura has a fan-

As the air heats up, the balloon rises . . . here is John Mickel (Officer Friendly on CB) getting just the right amount of hot air into the balloon to keep it upright yet not have it take off before everyone is ready.

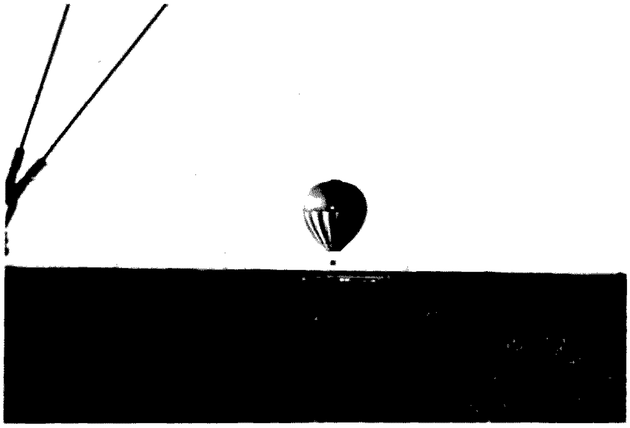


The W4SAC balloon about ready to take off, with 73 staffer and Marketing Manager Sherry Smythe just getting into the gondola.

Here's the W4SAC home and the second balloon about to take off for the historic ham QSO.



We're both airborne and the contact is made . . . W4SAC aerostat mobile four with W2NSD aerostat mobile four . . . roger over and out.



The two balloons rise and fall with the air currents and propane heating flames, making their way across southern Florida. Will Wayne be blown out to sea and never heard from again? No . . . Wayne is busy making contacts via local repeaters with his HT . . . keeping in touch with the ground crew . . . and talking with the W4SAC/4 balloon. Maybe next time.

73 staffer Sherry Smythe helped take the pictures for the article, including the beautiful cover shot. Working at 73 is not all on the level . . . sometimes it means odd things like ballooning.

Crunch lives up to his name by coming down solidly in an okra field a few miles from his home. By using just enough flames to keep the hot air right, it is possible to come down very gently.

tastic organ setup and she played some music for us . . . in all, it was a most successful day.

Balloons are fun . . . no question about that at all. They run from $5000 on up, and can stay in the air three to four hours on the two propane tanks. The balloon

Here's Will with his trailer . . . it carries the balloon and gondola for return to home. Will is the chap to see if you are interested in getting into the ballooning hobby . . . or maybe in renting a balloon for a hamfest.

W4SAC and 73's Marketing Manager Smythe wave as the first balloon-to-balloon ham contact is completed.

has a diameter of about 50 feet and goes up about 70 feet. It has a ceiling of about 20,000 feet . . . but this is higher than you want to go without oxygen. They'll lift about 400 pounds.

While you don't have a lot of control over which direction you are going to go . . . you go with the wind . . . you can control your speed quite a bit by picking an elevation which has the winds you want. We were able to slow down and wait for Captain Crunch and Sherry to catch up with us by staying low and waiting for the higher winds to bring them up to us.

I sure want to thank Will for setting up the event. He even brought in a second balloon from Atlanta for it. And I want to thank Laura, Walt, Ed, Nancy and Bill for helping out. Both Sherry and I had a wonderful time. Sherry had the same problems I did . . . she had binoculars around her neck, an HT in one hand, a camera in the other . . . and then she was told to hold on to the gondola!

What with trying to keep in touch with Captain Crunch in the other balloon, Ed on the ground, hold onto the gondola, and take pictures with various long lenses, I had my hands and knees full . . . and pockets. When you're about 500 feet up in the air you have a sort of automatic need to hold onto something. Tight. ■

The Surprising DDRR Low Noise Antenna

--part II

The intent of this two part article is to describe certain modern transmitting antennas of small electrical size useful to the radio amateur who has limited outdoor space available in which to erect radiators of conventional design. All the antennas discussed, such as the DDRR, LPT, and magnetic transmitting doublet, are forms of radiating rf transmission lines. Each is capable of rapid frequency tuning using very low loss variable condensers. Most are narrowly banded in frequency response due to small electrical size and low radiation resistance; this seeming limitation, however, turns out to afford a substantial improvement in signal-to-noise ratio during the receiving phase of the two way communications process.

By the end of Part I the reader had been provided with the relations needed to design a DDRR antenna for optimum tuning across any amateur band (or a bit more), and to match it directly to standard fifty Ohm coaxial feed transmission line to obtain low vswr across an entire ham band. Here the DDRR design will be completed and, in the process, any need for use of space-consuming radial wire ground plane systems will be removed.

Radiation Resistance of Small Antennas

Radiation resistance R_r can be defined in terms of the amount of energy an antenna loses per rf cycle to a distant space region occupied by all the other antennas in the universe (as compared to that supplied to its input terminals). The radiation energy loss must be related to a "distant space" region because in its "near space" an antenna also *stores* input power within a field surrounding its conductors. Such stored field power exists in the form of a standing wave,

the energy merely flowing back and forth between the antenna and near space during each rf cycle; this space standing wave antenna field is very much like that found very close to *open wire*, rf *transmission lines.*

As the size of an antenna shrinks in comparison to the wavelength λ at which it is operated, less and less of its supplied power is lost as radiation per rf cycle into the far space, and more and more is stored in its near zone standing wave field. By the definition given here, then, the radiation resistance R_r of electrically short antennas is small in value. Although the exact EM field process which creates antenna radiation is a complex subject, it is possible to give the radiation resistance of monopole antennas whose length h° is equal to or less than thirty-six electrical degrees quite simply. We will start off by giving two *engineering*-type axioms:

1.0. When an electrically short monopole antenna operating either over ground or its electrical image is brought to electrical resonance *solely* by placing a reactance jX_1 in series between its base and ground to cancel out the antenna's self-reactance, such an antenna possesses a current distribution yielding *minimum* radiation resistance in relation to its conductor length h in degrees.

2.0. When an electrically short monopole antenna operating either over ground or its electrical image is brought to electrical resonance *solely* by placing a reactance jX_2 in parallel with its top end and ground to cancel out the antenna's self-reactance, such an antenna possesses a current distribution yielding *maximum* radiation resistance in relation to its conductor length h in degrees.

The term "engineering" is used here in giving the two axioms because they are limited by the following premise: The loading reactances jX_1 or jX_2 are not themselves sources of wave radiation which is in phase opposition to the radiation produced by the short antenna. With such a restriction understood, the current distributions for these two types of reactance loading limits of the small antenna are given in Fig. 1 (a, b). Each antenna's current distribution is assumed to be in the form of a sine wave. However, the shape of the current distribution in each antenna is straight-sided because a plot of the function sine h° over a distance less than thirty-six degrees produces a graph which "looks" like a straight line.

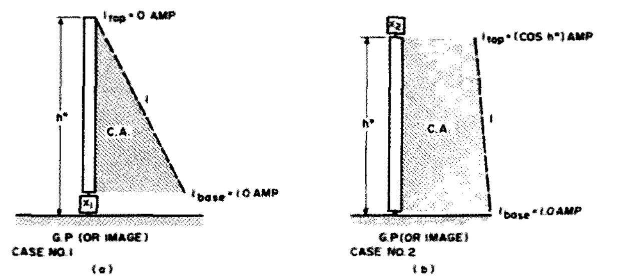

Fig. 1. Limiting cases of current distribution along electrically short, cylindrical monopole antennas resonated solely with (a) base reactance and (b) top reactance. Height h° is equal to or less than thirty-six electrical degrees.

In Fig. 1(a) for the short monopole solely base-loaded, the antenna current goes to zero magnitude at its conductor top end because at this point it is "open circuited" into free space. At the base of this monopole the *relative* resonant current amplitude there is assumed to be equal to 1.0 Amperes. Inside the straight-sided current distribution shapes of both antennas, the shaded region is labeled CA. This means current area or, more specifically: *relative current distribution area.* With the antenna height h° given in degree units and the current relative amplitude given in Amperes, these relative areas CA have the dimensions of *degree-Amperes.* For the solely base-loaded monopole of Fig. 1(a) (case 1.0), the triangularly shaped current distribution area CA is found from plane geometry as

$$CA_{(\text{base loaded})} = \tfrac{1}{2}\left[h^\circ\ (1.0\ \text{Amps})\right]\ \text{degree-Amperes} \qquad (2\text{-}1.0)$$

For the solely top-loaded monopole of Fig. 1(b) (case 2.0), the trapezoid-shaped current distribution area CA is

$$CA_{(\text{top loaded})} = \tfrac{1}{2}\left[h^\circ\ (1.0\ \text{Amps} + \cos h^\circ\ \text{Amps})\right]\ \text{degree-Amperes} \qquad (2\text{-}2.0)$$

In this case the current amplitude at the antenna conductor top is no longer zero Amperes; with resonance produced solely by the top reactance jX_2, the current I_{top} now equals (cosine h°) Amperes in relative value. The current I_{base} is still assumed to be equal to 1.0 relative Amperes. In terms of such *relative*[1] current distribution area CA, the radiation resistance R_r of short monopole antennas of height h° equal to or less than thirty-six electrical degrees is just

$$R_r = 0.01215\ (CA\ \text{degree-Amperes})^2\ \text{Ohms} \qquad (2\text{-}3.0)$$

Electrically short doublets in free space, of total length 2h°, have a radiation resistance R_r twice as large as that given by (2-3.0) when each "monopole" half of such doublet is loaded as stated here. Equation (2-3.0) is important in the design of electrically small antennas because it emphasizes that radiation resistance R_r is *not a constant* for a given monopole height h°, but may be increased by *control* of the current distribution along the short antenna.

Radiation Resistance of the DDRR Antenna

The reader may recall from Part I that the electrical height h° of the six foot vertical post conductor in the 75 meter band DDRR antenna was 8.78 degrees at 4.0 MHz. Viewed as a monopole antenna, Schelkunoff's equation (1-2.0) gave the average characteristic impedance of the four inch diameter conductor transmission line as K_m = 197.57 Ohms. It is noted that K_m does not enter into the expression for radiation resistance. If we wished, however, to use just such a post itself as a simple cylindrical monopole over ground, K_m would come in handy in determining the value of the reactance jX_1 needed to solely bring it to resonance at 4.0 MHz by *base loading:*

$$jX_1 = jX_{coil} = jK_m \cot h^\circ = j197.57 \cot 8.78^\circ = +j\,1{,}279.18\ \text{Ohms}$$

For the vertical post, used as a simple monopole antenna, (2-1.0) gives us the CA for this case as

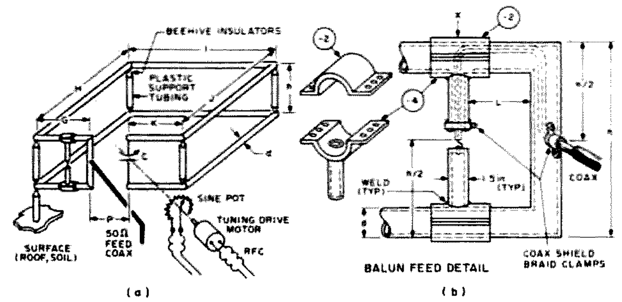
$$CA_{(\text{base loaded})} = \tfrac{1}{2}\left[8.78^\circ\ (1.0\ \text{Amps})\right] = 4.390\ \text{degree-Amperes}$$

The radiation resistance for this case would then be

$$R_{r(\text{base loaded})} = 0.01215\ (4.390\ \text{degree-Amperes})^2 = 0.234\ \text{Ohms}$$

Now, if the missing elements of the DDRR antenna system consisting of the horizontal ring transmission line section of S° and the tuning condenser C were restored and adjusted to resonate the DDRR at 4.0 MHz, we would have case 2.0. As cosine 8.78 degrees equals 0.988, this becomes the relative magnitude of I_{top} in Amperes, giving for CA:

$$CA_{(\text{DDRR})} = 8.729\ \text{degree-Amperes} \qquad (4.0\ \text{MHz})$$
$$R_{r(\text{DDRR})} = 0.926\ \text{Ohms} \qquad (4.0\ \text{MHz})$$



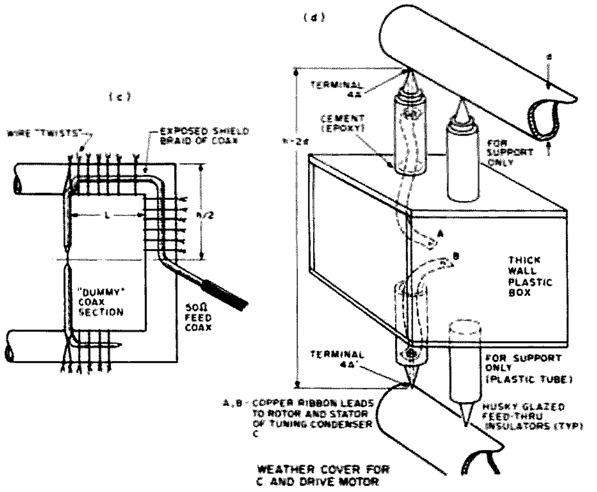


Fig. 2. (a) Construction suggestions for a ham band, "doublet" DDRR antenna. (b) Permanent unbalanced-to-balanced feed. (c) "Jury rigged" coax feed to find fifty Ohm input point X. (d) Suggested heavy plastic weather housing for tuning condenser, motor drive, and sine potentiometer; control wires to shack are brought out of box at right angles to DDRR conductors.

Needless three decimal place accuracy was used here because the current ratio I_{top}/I_{base} of the DDRR at 4.0 MHz closely approaches unity, giving almost a four-to-one increase in radiation resistance over the same monopole antenna solely base-loaded to resonance. A four-to-one increase in radiation resistance R_r represents the theoretical upper limit attainable for a short monopole antenna as compared to its R_r when solely base-loaded. Does that mean that the DDRR antenna actually reaches the theoretical limit of loading for short antennas? Not quite! This is where the limitation placed on the axioms comes in; because the DDRR tuning condenser C has displacement current I_{cap} flowing through it in proportion to its capacity setting, it represents a concentrated radiation source itself. As the current flow I_{cap} is in the *opposite* direction to the conduction current I_{base} in the vertical post monopole, the total effect is to "drive down" the effective radiation resistance R_e of the DDRR as a system. This effect is represented by the equation

$$R_e = R_{r(DDRR)} \left[1 - \frac{I_{cap}}{I_{base}} \right]^2 \text{ Ohms} \quad (2\text{-}4.0)$$

The detrimental effect on R_e of the DDRR represented by (2-4.0) is negligible at 4.0 MHz due to the high reactance $-jX_c$ of the tuning condenser set to minimum capacity. Although not serious, it becomes worthy of notice at 3.5 MHz. Hence the warning in Part I related to attempting to make one ring element cover two hf bands.

Frequency Bandwidth of Antennas

A practical way to describe the concept of antenna frequency bandwidth is as follows: Assume that at the resonant frequency f_o of the DDRR the correct feed point X (discussed in Part I) and ground produces an input impedance $Z_{in} = 50 + j0$ Ohms; a fifty Ohm coaxial line connected to the DDRR there would display a vswr of 1.0:1 at f_o. Now, *without retuning* the DDRR capacitor C, assume that the transmitter frequency only is increased to some higher frequency f_{high} where $Z_{in} = 50 + j50$ Ohms; then assume that the transmitter frequency only is reduced below f_o to some frequency f_{low} where $Z_{in} = 50 - j50$ Ohms. At frequencies f_{high} and f_{low} the feed coax vswr would increase to 2.6:1. The total frequency span $f_{high} - f_{low}$ is the *half power* width of the antenna. In the DDRR antenna case it is the *fixed-tune* half power frequency bandwidth. In the case of non-tunable antennas such as a half wave doublet, quarter wave vertical, yagi, etc., it is the antenna half power frequency bandwidth, period! Another way to describe this term is that at f_{high} and f_{low} the reactive part of antenna input impedance jX_{in} becomes equal to the resistive part R_{in}.

In Part I we mentioned that a transmission line antenna could be regarded as a highly *mismatched*, open wire transmission line "stub" section and that, due to such mismatch, the line stub possessed high amplitude standing waves along its length (*on* the antenna itself; *not* in the feedline to it). All hf antennas are forms of relatively mismatched rf transmission line stubs. The term "mismatched" is used in relation to a mismatch between the antenna wave impedance and the distant space wave impedance Z_o equals 377 Ohms. The lower the antenna radiation resistance value R_r is, (for a fixed value of ohmic environmental loss R_Ω), the higher the vswr on the antenna itself. The vswr on small antennas does not go to infinity to one, however, because a small amount of input power energy is (a) lost in the small but finite R_r and (b) lost into R_Ω in heating the antenna's near zone EM environment.

This vswr on the antenna itself can be related to the antenna half power frequency width or antenna Q. To get the right answers using conventional methods is very difficult and requires use of higher mathematics. Fortunately, Schelkunoff comes to the rescue in making things easy for us with his very useful expression for the characteristic impedance of an antenna as an rf transmission line. When you know K_m – and can calculate R_r from the simple equations (2-1.0), (2-2.0), and (2-3.0) – difficulties evaporate. All you need then are the following relations:[2]

$$m = \frac{K_m - R_r}{K_m + R_r} \quad (2\text{-}5.0)$$

$$Q = \frac{1 + m}{1 - m} \quad (2\text{-}6.0)$$

$$f_{high} - f_{low} = \frac{f_o}{Q} \quad (2\text{-}7.0)$$

As an example, let us take the calculations we just made for the case of the vertical post monopole element of the 75 meter band DDRR. Our K_m (regardless of loading) was 197.57 Ohms. When solely base-loaded, the DDRR monopole post alone gave us an R_r equal to 0.234 Ohms at 4.0 MHz. For this case,

$$m = \frac{197.57 - 0.234}{197.57 + 0.234} = 0.9976 \qquad Q = \frac{1 + 0.9976}{1 - 0.9976} = 832.33$$

$$f_{high} - f_{low} = \frac{4.0 \times 10^6 \text{ Hz}}{832.33} = 4.80 \times 10^3 \text{ Hz} = 4.80 \text{ kHz}$$

The same height post monopole of K_m = 197.57 Ohms, when solely top-loaded as an element of the DDRR antenna, produced an initial value of R_r equal to 0.93 Ohms. As C is set to minimum capacity at 4.0 MHz, its reactance is high and can be calcuated. Therefore, let us set $R_{e(DDRR)}$ equal to 0.850 Ohms at 4.0 MHz. Then again,

$$m = \frac{197.57 - 0.850}{197.57 + 0.850} = 0.9914 \qquad Q = \frac{1 + 0.9914}{1 - 0.9914} = 231.56$$

$$f_{high} - f_{low} = \frac{4 \times 10^6 \text{ Hz}}{231.56} = 17.27 \times 10^3 \text{ Hz} = 17.27 \text{ kHz}$$

Again here, we have employed needless decimal point accuracy to illustrate the method, using relations which are approximations. Nevertheless, the answers secured are useful. It is seen that using the monopole base-resonated with a *lossless* loading coil, the half power frequency bandwidth obtained is just barely wide enough to pass a 3 kHz SSB signal or CW-type transmission. Conversely, the same monopole — as part of the DDRR — would easily pass "high fidelity" double sideband AM; however, we based our calculations on R_r alone. As R_Ω adds to R_r in terms of the "dampening" of the vswr on the antenna system, both antennas would actually display a wider bandwidth found by substituting R_t equals $R_r + R_\Omega$ in (2-5.0). We don't know what R_Ω is in value as yet, but we certainly wish in some way to keep it to a minimum. Securing antenna bandwidth increase due to the "swamping" influence of R_Ω is a poor way to go, as it will drop antenna efficiency N as

$$N = \frac{R_r}{R_r + R_\Omega} \times 100\%$$

We will include the environmental ohmic loss resistance R_Ω in our discussion a bit later. Here is a critical point, however: In two-way hf communications, employing a *single antenna*, we wish to secure a total half power antenna bandwidth just wide enough to pass the data information rate to be communicated (CW speed, FM, SSB spectral content) while avoiding excess or redundant antenna bandwidth. During the transmission phase of our communications, an increase in antenna bandwidth of fifty octaves or more greater than we need doesn't count one way or the other. In the reception mode of our two-way communications, however, excess antenna bandwidth permits more random noise to pass and load the front end of the receiver to effectively decrease signal-to-noise ratio. Too wide an antenna bandwidth also increases the QRM we experience on the desired signal we are trying to copy in the presence of strong, just-off channel carriers. Modern communications receivers rely heavily on i-f selectivity. Here, we wish to assist the front end stages of the receiver by placing a narrow, tunable, "bandpass filter" between them and the rf universe — in the form of the antenna.

I said "tunable!" That is a key factor here. When we use antennas which exhibit a narrow but just "wide enough" bandwidth, we must be able to move this filter "slot" quickly in frequency to carry on practical hf communications. If we secured such a narrow frequency width "slot" from an electrically small antenna resonated solely by the lowest possible loss, extremely high Q loading coil placed very high up in the monopole (to increase CA), the instant we tried to vary the coil inductance (by coil taps, turn sliders, etc.) and change the frequency of resonance, effects from eddy currents and consequent departure from optimum coil shape factor would immediately run up coil loss — and the antenna radiation efficiency would plunge downward. An air or vacuum condenser is of exceedingly high Q at a given capacity setting; varying capacity over wide limits to change antenna frequency hardly affects condenser Q at all.

An Image for the DDRR (and Other Transmission Line Antennas)

Those among the ham brotherhood who hold calls with only two letters after the area prefix may still remember a device now relegated to moth balls together with the spark gap, galena detector, and super-sensitive regenerative receiver: the *counterpoise* (especially the *tuned* counterpoise). The counterpoise was placed under your linear monopole, "T", or "L" antenna when there was less than $\lambda/2$ horizontal space area diameter available in which to lay out a radial wire ground system on the soil. You found it very curious: If you did go ahead and lay out n number of electrically short radial wires on the soil and operated the antenna, you got some value of radiation efficiency N_1 from the total antenna/ground system. But if you (a) lifted the same n number of short radial wires a bit above the soil, (b) insulated the whole system of n wires from soil ground, and (c) then tuned *each* short radial wire in the system to resonance at f_0 using individual series *loading coils* — if you did that, you obtained a substantial improvement[2] in total antenna system efficiency.

The old-time professional antenna men who first observed this phenomenon said to themselves, "Wow, this is really weird! For some reason my insulated, tuned wire ground system collects more electric E lines of the antenna near zone field and returns this energy back to the antenna input terminals with less total ohmic loss R_Ω than the same number of short wires just laid on the soil surface!" Unfortunately, space does not permit our having a QSO at this point about the beautiful phenomenon of rf soil and space current (displacement) diffraction which relates to this very effective but now almost forgotten low frequency antenna technique. It can only be noted that such electrically small, insulated and tuned counterpoise systems even permitted erection of monopole antennas on the roofs of tall municipal buildings in the early days of BC radio where the small roof space there didn't offer a prayer's hope for use of a conventional wire "ground" system. The *tuned* radial wire counterpoise worked well. A de-tuned radial wire system, however, was inefficient by comparison. Therefore, the tuned radial wire counterpoise was just fine for use in *one way: fixed frequency* broadcast type transmission. For use in two-way hf communications where frequent and rapid frequency changes are necessary, it is an impractical nightmare! You have to retune *each* of those series loading coils — n of them! An automated system to do this would not only be a Rube Goldberg mechanical mess, but run into the same efficiency problem in varying coil inductance mentioned a ways back. Now, we said *radial* wire ground system!

In Fig. 3(a) of Part I, you will notice that the image currents flowing in a continuous surface, electrical "mirror" ground plane beneath a DDRR antenna are *not radial* in geometry. Instead, the image currents of the DDRR flow around in circles, going in the opposite direction to the currents flowing in the ring conductor just above them. Very careful

laboratory measurements carried out on a 5λ by 5λ sheet copper ground plane beneath a DDRR show that these image currents do not begin to turn outward radially until you get at least λ/8 distance away from the ring conductor. At such a distance, these image currents are very weak in magnitude; they do not decay by the 1/r rule at all. It was found that DDRR antennas of the purely monopole form did not operate efficiently when placed over a true radial wire ground plane — only over sheet metal mirrors. Of course, in the case of the *U.S.S. Wheeling* DDRR, we had a pretty good approximation to such a sheet metal mirror in the form of the hangar roof, welded ship's structure nearby, and that immense surrounding sea plane, so we used it effectively. But what if the Navy had asked us to errect that 2-30 MHz DDRR on *Old Ironsides* (all wood in spite of her heroic name)? Well, we would have just said, "Aye, aye, Sir. You can have it on the teakwood deck or at the peak of the foremast."

This is the way we would have handled the job on the double:

Under each of those overhead, separate frequency band DDRR ring elements we would have placed a "mirror" image ring conductor — an exact duplicate ring, using the same tubing conductor diameter d, same circumferential length S°, and so forth. Instead of each of those tuning condensers C being connected to the metal roof of the helicopter hangar at terminals 4G, each would have been returned to a duplicate terminal 4A' on the image ring conductor below. In such a conversion to a mirror image DDRR, we would not have increased the vertical height h at all. Instead of the view of each of those fiberglass posts which we see in Fig. 1, Part I, supporting the DDRR ring elements in parallel alignment above the hanger roof, we would now see another beehive insulator at each's base end, used to hold the two ring conductors in parallel alignment. Unlike that system of radial wire, tuned images in the old counterpoise system, however, there would be no need for a bull gang of sailors to rush out on deck each time a QSY was needed to start madly grid dipping all those series loading coils to the new operating frequency. Instead the operator, in the comfort of the shack, would merely push the DDRR tuning control button. Because the two ring elements are mirror images of each other, tuning condenser C would now move the entire DDRR system to the new operating frequency f_o as before. Of course, the converted Navy DDRR now sitting on the mizzen forepeak of *Old Ironsides* would no longer be a monopole: It would be a DDRR *doublet* antenna: still vertically polarized, still a low angle, omnipattern antenna. Its radiation resistance R_r(doublet) would remain unchanged. This is because, although you would use now ½h (instead of h) to get CA from equation (2-2.0), you would multiply the answer you get from the monopole radiation resistance equation (2-3.0) by two for the doublet case. Finally, although this is not a "construction" article, Fig. 2 is included to guide the amateur experimenter who desires to complete a compact size DDRR and put it on the air.

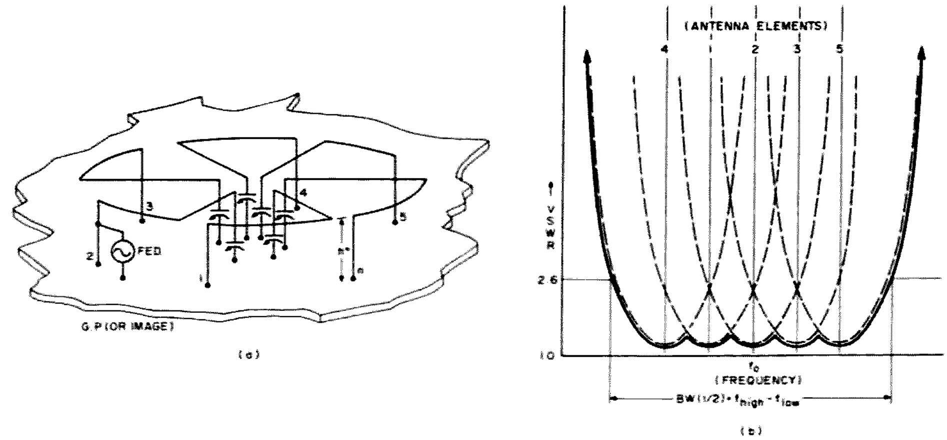
From Fig. 2 you see that the minimum size ham band DDRR is a single post model. Also, because it is costly and difficult to form large diameter tubing into circular shape, the ham band model has a square shape: *square*, not rectangular. The total path length G + H + I + J + K should be equal to the length S° you obtain from the relations in Part 1, with H = I = J = G + P + K. In an hf band DDRR, the gap P between the tuning condenser end and the monopole post should be about 1.5 degrees at the high frequency end of frequency coverage. *All* ring conductor joints *must be welded.* This means heliarc welding, when high conductivity aluminum tubing is used. Please don't use automobile exhaust tubing or cad-plated conductors. Contact resistance and conductor loss spells disaster in electrically small antennas, due to the high magnitude currents in such radiators. Oh yes — use an absolute minimum diameter of 3 inches for the conductor diameter in antenna elements operating lower than 7.3 MHz. The smaller K_m (equation 1-2.0) gets, the higher both efficiency and bandwidth (fixed tune) becomes. As the image doublet DDRR requires no other ground plane, most users will probably mount it on a roof of some kind (garage, house, pole). When the height above ground is at least equal to h, use the formula

$$K_c = 276 \log_{10} \frac{2h}{d} \text{ Ohms}$$

instead of equation (1-1.0) for the characteristic impedance of the horizontal transmission line section (in getting the needed capacity values for tuning). The change in K_c of the image DDRR does not impair performance of the antenna when in operation.

Finally, it is seen that if we are dealing with a "doublet" DDRR, the "base" terminals 1A,1G of the "monopole" are now located at the *center* of the vertical post. The doublet requires a balanced rather than unbalanced feed, yet we still want to feed it with a coax line to the shack. OK — as seen, the coax line from the shack now *enters* the vertical

Fig. 3. (a) Low Profile Tunable (LPT) antenna operated in parasitically-coupled, wide passband, single channel mode using n elements. (b) Typical vswr versus frequency curve; solid line indicates half power frequency bandwidth of total array; broken lines indicate individual vswr response of each coupled element.



post via a hole through the conductor wall at ½h, then is pushed around inside the top horizontal element conductor, passes down through a hole in its *bottom side*, and continues on down the inside of a .5 inch o.d. thin wall tubing section to the ½h point.

At this point, the shield of the coax is folded back over the outside of the feed tube and clamped in contact with the metal. The coax inner conductor spans about a one inch gap to connect to the upper end of another 1.5 inch feed tube extending down to the lower "ring" conductor. You need first to determine the location of X for this balanced feed arrangement.

In Fig. 2(c), a suggestion is given for a *temporary* arrangement of coax to locate X and spacing L from the vertical post. The black vinyl coax jacket is stripped back to expose the shield braid over a sufficient length section of coax end. An additional "dummy" length is cut off and the inner conductor and shield shorted together to make a bottom feed section conductor. The aluminum tubing is polished with sandpaper to permit *good* electrical contact, and the coax line section temporarily "jury rigged," as shown, at a trial spacing L. Loops of wire "twists" are used to hold the coax shield in contact with the aluminum ring conductor and post. With the rig tuned to the *center* of the band, vary dimension L carefully until a vswr of close to 1.0:1 can be secured in the feed coax when tuning condenser C is "tweaked" to bring the DDRR to resonance at the transmitter frequency. With the temporary feed tightened down at this X location, now tune the rig up to the desired top frequency of tuning for that band element. If, without relocating the feedpoint X, a vswr of at least 2:1 cannot be attained at the f_{high} with tuning condenser C close to its minimum capacity, a bit of "pruning" is needed. Small, equal length conductor sections must then be removed from the conductor ends 4A, 4A' until a clear minimum vswr dip is observed at the high frequency end of coverage with C close to minimum capacity. The exact minimum vswr is not important, but the "dip" in vswr should be clearly seen. The location procedure for X at the *center of the band* must then be repeated until a 1.0:1 vswr is secured with the DDRR resonated by tuning C. It will then be found that the vswr will be less than 2:1 at both the high and low band limits for a fixed feedpoint X. The "jury rigged" coax feed is then removed and the permanent feed conductor system substituted. When cutting the hole to pass the coaxial line on the underside of the top horizontal tubing conductor, the hole should be elongated about one inch on either side of the X location to permit "inching" the permanent feed in final tests for vswr. An old-fashioned tube "socket" die cutter is handy for this purpose. Warning: *Do not* attempt to make the above described matching rests until (a) the DDRR is mounted at its permanent site and (b) the tuning condenser C is mounted inside its plastic weather housing and connected across the points 4A,4A', as shown, using beehive or cone feedthrough insulators.

An idea is suggested for cementing up a plastic weatherproof housing for both the high voltage tuning condenser, motor drive, and simple tuning frequency indicator. See Fig. 2(d). Note that although the plastic box is in the intense electric field at the tuning position, the actual leads (copper shim stock ribbons about 1.5 inches wide) to the tuning condenser rotor and stator terminals are insulated solely by the glazed ceramic insulators on the box. The leads should not be permitted to touch the plastic walls anywhere. Small ceramic button insulators space the condenser off the internal plastic mounting shelf inside the box. The *shaft* of the tuning condenser is also *isolated* from the motor and tuning indicator by means of a high quality rf shaft coupling insulator.

The condenser should be remotely controlled from the shack by a reversible, voltage speed controlled motor. Its shaft speed should be such as to permit "high speed" tuning across the entire band in about one half minute, yet slow enough to "tweak" the DDRR right onto channel center at f_0. An efficient DDRR is quite sharp in tuning. Once X is set correctly, you will find yourself tuning by means of the sharp receiving "noise peak." Hunting around the band, you will "tweak" this receiving gain point of the DDRR along the dial with the tuning control, as if the antenna were a dog on a long leash. A simple frequency setting indicator is suggested in the form of a sine potentiometer geared 1:1 to the motor shaft. At the shack end a dc meter calibrated in frequency for the current in the sine pot is a help in operating the DDRR. Otherwise, spin the receiver dial until you spot the noise peak – that's where the DDRR is. Small rf chokes should be placed in series with both the motor and sine pot leads at *both* the remote antenna weather box and shack end terminals. In multiband DDRR models, elements for the other bands are mounted concentrically to one another and operated as separate systems, each being designed according to the relations given in Part I. When in the process of finding the feedpoint X for these other band elements, make sure all other band rings are tuned off from harmonic relationship with the tested ring element. Oh yes, a final word: In a multiband model DDRR, the field coupling isolation between ring elements is very large in value so that even simultaneous working can be carried on in two bands. If, however, you suddenly find it strangely impossible to get low vswr tuning at some spot frequency in a given band, this means the ring element in the *next lower* band is tuned inadvertently to a "subharmonic" relationship. No problem: A touch of the tuning button to the offending band element easily cures this.

We have devoted considerable space here to the DDRR antenna. Fortunately, this detail is not for naught; understanding the DDRR not only permits us to grasp quickly the function of other transmission line antennas, but gives us a deeper appreciation for the small antenna problem in general: both the good and the bad of it.

The Low Profile, Tunable (LPT) Antenna

The narrow frequency bandpass nature of electrically small antennas of high efficiency has been noted. There are certain modes of transmission, even in amateur service (double sideband AM, FSK teletype), and in commercial and military practice (Loran, hf radar, "data burst"), where a wider fixed frequency bandwidth is desired. If it is also necessary, for various installation or tactical reasons, that an electrically small antenna be employed, a serious problem results. Conventional antenna practice would indicate sacrificing antenna radiation efficiency by letting R_Ω in the system increase to obtain the necessary bandwidth. Such practice even goes to an extreme called "swamping," where actual ohmic resistors are connected across the

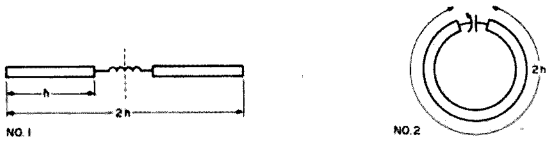


Fig. 4.

small antenna input terminals.

One version of the LPT transmission line antenna[4] answers this need for securing a controllable width frequency bandpass from an electrically small but efficient antenna. Shown in Fig. 3(a), the LPT antenna of this form consists of n number of radially aligned antenna transmission line elements of small size. Each is tuned at one end by a shunt variable tuning condenser. The "post" at the perimeter end of the short length circumferential conductor section is "grounded" to serve as a monopole antenna. Naturally, a "mirror image" doublet scheme can be used here, as in the DDRR, to improve efficiency. Our familiarity with the DDRR antenna principle would allow us to easily design these LPT elements as well.

However, it is noticed that only *one* of the vertical posts in the array of n antenna elements is actually fed rf power, as indicated by the "generator" symbol. In Fig. 3(b), the explanation for this strange configuration is made clear. In a manner analogous to the operation of a "stagger tuned" i-f transformer in a wide band receiver, all the other tuned elements in the LPT array are electromagnetically coupled to the driven element as parasites. Each of the n parasitic elements is tuned to a slightly different frequency above and below the center f_o of the radio channel. The staggered, overlapping frequency responses of the n element array results in a *single* overall frequency passband. The vswr "ripple" across the frequency passband is governed by the number of parasitic elements employed in the same way that the ripple in impedance response of a bandpass filter is governed by the number of network sections used. The analogy is almost exact, except that we deal here with radiators of EM waves. Not shown are small details such as provision for auxiliary reactors to control the coupling coefficient between elements to secure "overcoupling" if desired.

In amateur service where bandwidth increase need is modest, only a few elements would be required, making such an antenna practical, say, for 160 meter application. On the other hand, for such a small antenna to pass the forty microsecond width shaped pulse from a Loran transmitter without distortion, more parasitic elements in the LPT array would be required. There are other forms of the LPT for use in services requiring a large number of n transmission channels over, say, the 15:1 span of the hf spectrum from 2 to 30 MHz. Others can establish the so-called Bessel function circular array to produce directional beams which can be "slewed" rapidly in direction at hf similar to early German WWII radar systems. These do not find application in amateur service, however, and will not be detailed here.

The Loop or Magnetic Transmission Line Antenna

Take two equal length sections of aluminum tubing of conductor radius a. Call their respective equal lengths 2h, where 2h° is only twenty electrical degrees at f_o; calculate the K_m of of a section h° in length. Label one straight section "number 1," and then cut it exactly in half. In a very small gap left at the center of length 2h, connect a *lossless* loading coil whose inductance is

$$\tfrac{1}{2}(X_{coil}) = \tfrac{1}{2}K_m \tan 10°) \text{ Ohms}$$

Bend the other conductor, labeled "number 2," into a circle whose circumference is 2h°, leaving a small gap between the ends of the conductor. In this gap connect a lossless series condenser whose reactance is

$$|X_C| = |X_{loop}| \text{ Ohms}$$

where the reactance X_{loop} is that of the one turn loop inductor. The two electrically small, reactance loaded antennas will then look like Fig. 4.

Excite both the number 1 and number 2 antennas with rf at f_o. Now take measurements of the electric E and magnetic H parts of the fields produced by each of these two antennas, starting out very close to their conductors and then moving away in steps until a very large distance r/λ is reached. Your results will look like Fig. 5.

Very close to the straight, coil-loaded number 1 antenna, it can be seen that the electric E field is extremely large in intensity, while the magnetic H field part is minute in strength; in this near zone region the field ratio E/H is immense in value. At increasing distance from the number 1 antenna, however, this E/H field ratio decreases until at large r/λ distances it approaches a value of 377:1. Over on the right, we see that the result for the case of the loop antenna, however, is just opposite; now it is the magnetic H field which is tremendously strong near the conductor and the electric E part of the field which is very weak in intensity. The E/H ratio, in this case, is close to zero in the near zone. Yet as the distance r/λ from the number 2 loop antenna increases, we see that the E/H ratio value still ends up at the same magnitude of 377:1. Because of the radically different but "dual" nature of the near zone fields of these two *basic* types of antennas, the number 1 antenna is called an *electric* antenna; number 2 is called a *magnetic* antenna. So far this sounds like boring textbook stuff; who cares about this fancy near zone field phenomenon? We're hams – practical radio communicators. It's that far zone DX field we are really interested in, right? No, wrong! – as you will see in a minute!

Saw number 1 doublet antenna in half, cutting right through the *center of the loading coil.* You now have made it into an electrically small, coil-loaded monopole antenna of length h°. But it won't work! You must now stick either a flat metal sheet or a set of resonant radial wires under this number 1 antenna to get it oscillating again at f_o as a resonant monopole over this necessary electrical "mirror": You need a ground plane. However, the little condenser-resonated magnetic loop antenna keeps working nicely with or *without* any ground plane beneath it; it doesn't need one. The

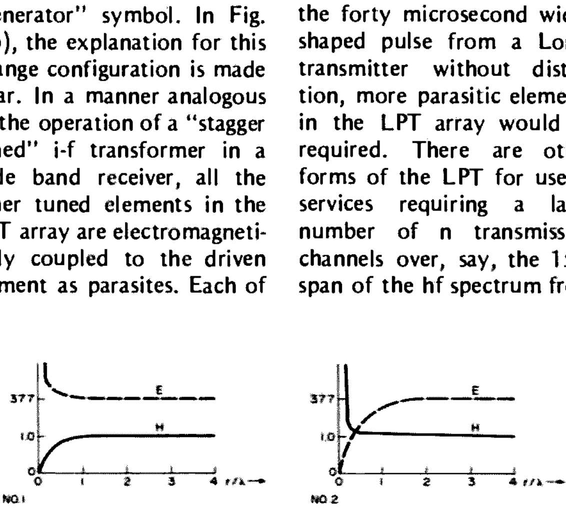

Fig. 5.

loop or magnetic antenna is *always* a doublet. There is also another, very critical, *practical* difference between these two basic kinds of antennas.

Take identical masses of real world dielectric matter such as soil, rock, vegetable tissue, etc., both containing equal amounts of moisture. Set the radial wire "mirror" part of the vertical electric monopole down onto one pile of such matter and the magnetic loop down on the other pile of this real world stuff. Immediately the temperature of the matter beneath the electric antenna will rise; part of the near zone field energy of the electric monopole is being lost into heating the dielectric matter. A check of the same kind of matter beneath the loop, however, shows almost no antenna near zone field energy loss – almost no heating. The tiny amount of heating which *is* taking place is entirely due to the small value of the electric E field in the near zone necessary to make up an *electromagnetic* rf field. The H part of the loop antenna field could care less about the presence of this wet dielectric matter near to it. Theoretically, equal input power fed to ideal electric and magnetic antennas of the same small electrical size in free space, when resonated with reactors of equal ohmic loss, will produce identical amounts of radiated energy at great distance in λ. This is *not the case* when the same electric and magnetic antennas must be erected near to real world, lossy dielectric QTH environments. Under these real world conditions, the electrically small magnetic loop antenna wins the antenna efficiency race over the electrically small electric antenna. By now you are thinking, "Boy, what a neat antenna that loop is!"

You would think, from what has been said up to

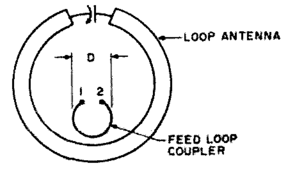

Fig. 6.

here, that communicators would use the magnetic kind of antenna exclusively in at least the hf and lower frequency radio region where antennas must be erected over this lossy, mostly dielectric planet surface of ours. When radio was born in the first spark transmission experiments carried out by Heinrich R. Hertz (1888) in verifying James Clerk Maxwell's prediction of the existence of rf waves, a loop antenna was employed. Since then, however, it is the electric type transmitting antenna which has ruled the ether waves. The loop antenna has been relegated almost completely to receiving service, particularly as a direction finder, where its twin, narrow width pattern nulls give accurate bearings. Why is this? First, the radiation resistance of a small loop is

$$R_{r(loop)} = 31{,}200 \left[n \frac{A}{\lambda^2} \right]^2 \text{ Ohms} \qquad (2.7.0)$$

where A is the årea of space enclosed by the loop conductor in the same units as λ, and n is the number of turns in the loop. This $R_{r(loop)}$ comes out to be a very low number value when the area A of the loop is small in terms of wavelength. As mentioned before in relation to the DDRR antenna's "base" impedance, this makes it very difficult to make an impedance match between the resulting small value of $Z_{in(loop)}$ and the Z_o of a standard feed transmission line. The always necessary complex network or transformer is inconvenient, invariably gives added ohmic loss, and must be "track-tuned" in step with the antenna. Some invention is required in the form of a simple, efficient coupler between the loop itself and the transmission line which does not itself need tuning.

Another problem is that, due to the very small value of $R_{r(loop)}$ – when the loop inductive reactance is canceled out by use of a *series* tuning condenser at f_o – the rf current circulating in the electrically small resonant loop at, say, one kW power input can get up to one hundred Amperes or more. Like the DDRR, therefore, you just don't make *transmitting loops* out of wire conductors; you use large cross-sectional diameter, highly conducting tubing. Finally, because the loop inductive reactance jX_{loop} is quite small in an electrically tiny loop of few turns, the small $-jX_c$ of the condenser spells lots of capacity in Farads. Although $-jX_c$ is not large in Ohms, the appreciable current magnitude in the loop produces a respectable magnitude of $|jX_c$, so the voltage rating of the tuning condenser is in the high hundreds to a few thousand volt range at one kW peak power.

Loop antennas will work well even when buried in the soil. During WWII, German submarines in "wolf packs" used loop antennas to communicate over relatively short distances while submerged.[5] Knowing all these facts, the U.S. military over the last few years has been field testing a loop transmitting antenna in the 2-30 MHz frequency range at power inputs up to one kW. Needing no ground plane and being of conveniently small physical size, it is well suited to "quickly transportable" two-way radio communications (field day?) applications. However, what makes this new loop transmitting antenna practical and efficient at long last is the ingenious patented[6] way it is matched in broadband fashion to the feedline. One form of this feed invention looks like Fig. 6.

A balanced two wire feed transmission line is connected to terminals 1,2 of the small feed loop of diameter D. As in the DDRR, all you do is tune the main loop variable condenser for resonance at f_o, then experimentally change D while "tweaking" the condenser to obtain a minimum vswr reading in the feedline. At the correct diameter D, feedline vswr will fall to 1.0:1. Once D is found, it need not be changed in order to get a good match over a large frequency tuning range. There is no need to actually make electrical contact between the base of the small feed loop and an adjacent point on the main loop conductor; coupling is achieved to the main loop antenna's H field. As expected in a magnetic antenna, even a sheet of varnished plywood can be used to hold the coupling loop in alignment while obtaining negligible dielectric loss. The feed loop can be made of, say, one half inch o.d. copper refrigerator tubing.

For ham band service in the lower hf range, main loops of from eight to sixteen feet in diameter would be practical, made from one or two turns of two inch or larger o.d. thin wall aluminum tubing. Naturally, they can be made square in shape instead of round. All main loop conductor joints must be welded, and husky "ribbon" leads made to the variable tuning condenser. The large total capacity size needed in the condenser for 160/75/40 meter band use could be attained by shunting a smaller size variable air or vacuum condenser with less expensive *fixed* air or vacuum

insulated condenser units. Only the tuning condenser and associated components like a drive motor need be protected by a plastic weather housing.

A little ham ingenuity would result in easy, inexpensive ways to mount and rotate such a transmitting loop antenna and even remotely tune it to resonance from the shack. The very sharp twin nulls in the horizontal pattern plane can be used effectively to slice through QRM by pointing one of the nulls in the direction of the interfering station – sort of like using a 160 meter "beam" antenna. The very broad width maximum lobes of the pattern produce almost omni-response to desired signals. One last but important word: The loop/coupler is a patented concept. No consideration should be given to manufacturing a loop antenna incorporating this excellent idea for sale without legal arrangements being first made with the listed patent holder. ■

Footnotes

[1] Relative amplitude is necessary in such relations because the radiation resistance of an antenna is not dependent upon the actual current magnitude – only its geometric shape of distribution. If this were not so, R_r would vary with changes in the power input to the antenna.

[4] U.S. patent: J. M. Boyer, #3,680,135.

[5] Long range underwater radio communications is inefficient; this is *not* due, however, to any appreciable loss in the submerged loop antenna. It is due to the conductivity of water "shorting" the radio waves' E field at a large distance in λ, where the E/H ratio becomes appreciable.

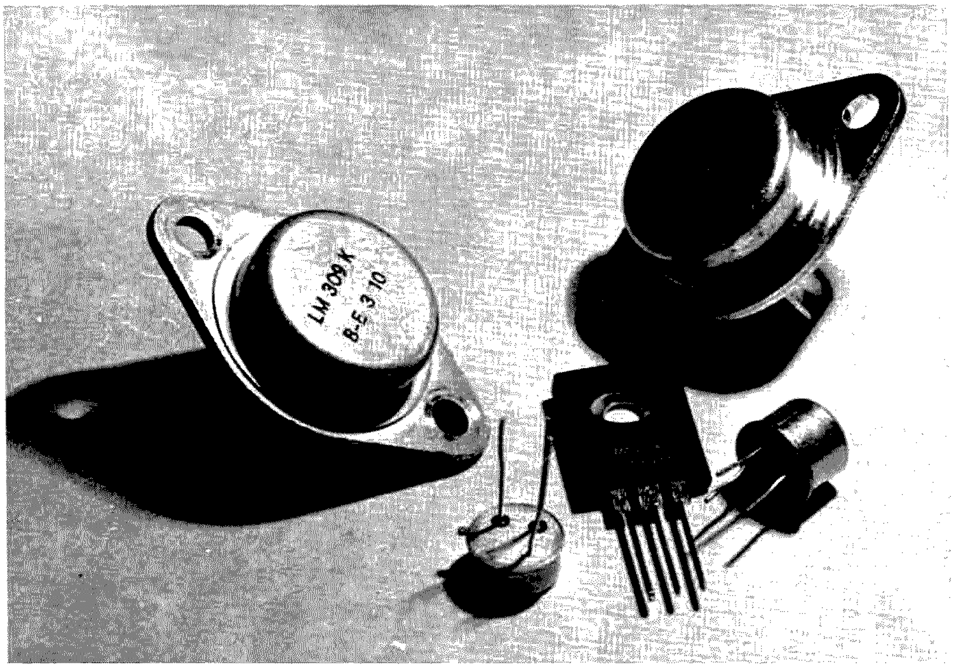
Ultrasimple Regulation with New IC

- - power supply design greatly simplified

James Kucera WB0JLS
1477 Brenner Ave.
St. Paul MN 55113



Three terminal IC regulators, available in a wide variety of voltage ratings, current capacities, and package styles, are easily used to make high quality power supplies.

Some time ago there became available to the electronics experimenter a number of three terminal monolithic integrated circuit voltage regulators. With a minimum of external parts, these ICs can be easily and inexpensively used in the design and construction of high quality, low voltage regulated power supplies.

In this article I am going to explain the basic use of the LM309 and uA7800 series of regulators. They are all fixed voltage units, most exhibiting a continuous duty current capacity of one Ampere. Available through many surplus dealers, they cost under two dollars, and the price is still going down, *in single unit quantities!*

There are many other regulators available on the surplus market, but I have chosen to describe only the LM309 and uA7800. However, if you spend a little time studying the published data sheets on other units, I think you will find that most of the circuit design procedures I have outlined here are directly transferable to use with other three terminal regulators.

Parts Selection

The specifications for the regulators I am describing are shown in Table 1.

Fig. 1 shows a practical power supply circuit, using any one of the regulators in Table 1. It needs no additional parts. It will work with all of these three terminal devices by simply varying a few component values and ratings.

Fig. 2 is also practical: If you cannot locate a center-tapped transformer, replace T1 and D1-D2 from Fig. 1 with the transformer and bridge rectifier circuit shown in Fig. 2. The full wave rectifier is preferred, because of the smaller diode drop of the two diodes in Fig. 1 than of the four in Fig. 2, but the difference is not that crucial.

Now let's assign some values to the components in those circuits. Use Table 1 to determine what regulator to use for IC1. Make your choice on the basis of voltage rating and current capacity.

Refer to the graphs in Fig. 3. There are five graphs for use in determining the T1 transformer voltage and C1 filter capacitance for five separate one Amp regulators. The transformer voltage is for a center-tapped transformer with a full wave rectifier, as in Fig. 1. If you use the bridge rectifier configuration from Fig. 2, halve the transformer voltage but remember to *add one volt* to compensate for the voltage drop of the extra diodes. If you use the schematic from Fig. 1, the current capacity of T1 need only be half an Amp – or half of what you want the completed supply to deliver. The lower voltage transformer needed for the less efficient bridge of Fig. 2, however, must be rated the full Amp.

Filter capacitor C1 should be an aluminum computer-grade electrolytic. If you have any question concerning interpolating a capacitance to use with any given transformer, round *up*. This will help to make up for component tolerances and line voltage fluctuations. Since readings off the graph are minimum allowable capacitances, you might want to use a larger value capacitor anyway.

Since the graphs were calculated using one Ampere of drain, if some fraction of an Amp is to be drawn, the C1 value can be reduced by that fraction. For example, if only 100 mA is needed, then only one tenth the capacitance is necessary, or any other such fraction. It works the other way around, also – if you make a ten Ampere supply (with a pass transistor), you will need ten times the filter size.

Exercise prudence when calculating capacitor voltage ratings. Use at least one and a half times, but preferably twice, the rms transformer voltage across the capacitor.

Do not omit C2. It is an rf bypass capacitor, especially necessary if the power supply is to be used in an area of strong rf such as a ham shack – but still needed even if used elsewhere. C2 helps to absorb the spikes and glitches on the line that are too sharp for C1 to respond to. It can be anywhere from around .10 uF to .33 uF – .22 uF is a happy medium.

Selection of the value of the output capacitor (C3) need not be very exacting. You can use anywhere from around .005 uF to a couple of microfarads. Generally, use larger values for larger currents. A common value for a one Amp supply is about a 1 or 2 uF tantalum. Some of the manufacturers' data sheets insist that it is not needed, but, since the very next phrase in the paragraph is always that its presence "helps to improve transient response," I would not suggest omitting it.

These regulators do not work well at low current drains – around 5 mA and under. Therefore, R1 has been calculated to draw about 5 mA from the supply. A half or quarter watter is sufficient. A pilot light (LED or incandescent) could be wired in to serve the same purpose. If the supply is being built into a project so that the drain is never allowed to go below 5 mA, R1 could be altogether eliminated.

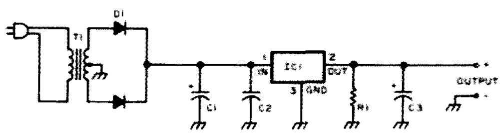


Fig. 1. Here is a practical diagram for a power supply of any voltage, needing no other parts. Use this schematic with center-tapped transformers in a full wave rectifier configuration. Regulator voltage/R1 value: 5/1.0kΩ, 12/2.2k, 15/2.7k, 18/3.3k, 24/4.7k.

Device	Current	Voltage	Package
LM309H	200 mA	+5 volts	T0-5
LM309K	1.0 Amp	+5 volts	T0-3
uA7805	1.0 Amp	+5 volts	T0-220
uA7812	1.0 Amp	+12 volts	T0-220
uA7815	1.0 Amp	+15 volts	T0-220
uA7818	1.0 Amp	+18 volts	T0-220
uA7824	1.0 Amp	+24 volts	T0-220

Table 1.

The choice of rectifiers for D1 through D4 is not at all critical. The graphs were compiled using 1.3 volts as the forward diode drop. This figure is based on the 1N4000 series silicon one Amp rectifiers. It should be close enough for interchanging with any of their surplus equivalents or replacements. 1N4002 or 1N4003 diodes would be a good choice for any of the transformer voltages on the graphs. Some of the lower voltage units can even get by with 1N4001s. Just make sure that you don't exceed the diodes' piv ratings.

Automotive Applications

There are many times when you want to operate a transistorized device in your car that requires a supply voltage different from that of the standard 12 volt automotive electrical system. A higher voltage requirement would take a power convertor exceeding the scope of this article, or a separate battery. But these IC regulators are ideal for obtaining lower voltages from the 12 volt electrical system. Fig. 4 is a supply circuit tailored specifically for use in a car.

An automotive environment is, however, very prone to transience. Special precautions should be exercised to protect the regulator. Positive spikes on the input line can very easily cause that input terminal to go above the maximum allowable input voltage for the IC. Therefore, the zener diode (Z1) has been put into the circuit to help shunt any higher spikes to ground. You can use whatever zener you have in your junk box in the 24 to 30 volt range.

The rectifiers are absent in this version, but note that the filter capacitor is still there. Keep it there – your car's alternator puts out an awful dc waveform. Filtering is still needed.

All of the other parts are the same as the other circuit diagrams.

Construction Considerations

The construction considerations you need concern yourself with when using these IC regulators are not very numerous. But those that do exist should be carefully observed.

There are definite reasons for the endpoints of the graphs in Fig. 3. *Do NOT extrapolate transformer voltages from either end of the graphs.*

These regulators will only work when an input voltage between certain limits is present at the input terminal. The dropout voltage, or level below which the unit will not operate properly, is usually two volts greater than the rated output voltage. Thus the LM309 needs an input of at least 7 volts to work correctly. If the input is too low, it will not regulate at the desired voltage and the ripple will be excessive.

The input level to these regulators cannot be too high,

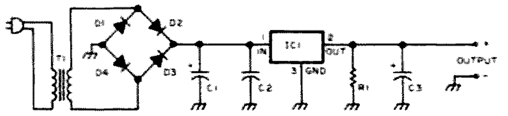

Fig. 2. If you cannot locate a center-tapped transformer, substitute this schematic for that of Fig. 1. Keep in mind the additional design considerations explained in the text necessitated by the extra diodes.

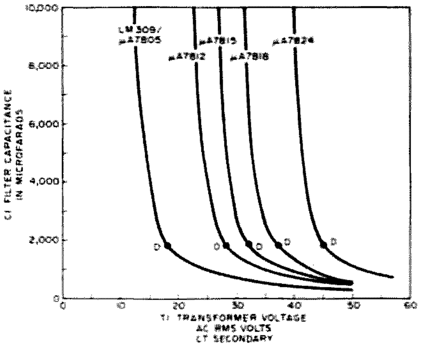

Fig. 3. Use this graph for determining C1 capacitance and T1 voltages. The points labeled "D" are the dissipation limits explained in the text.

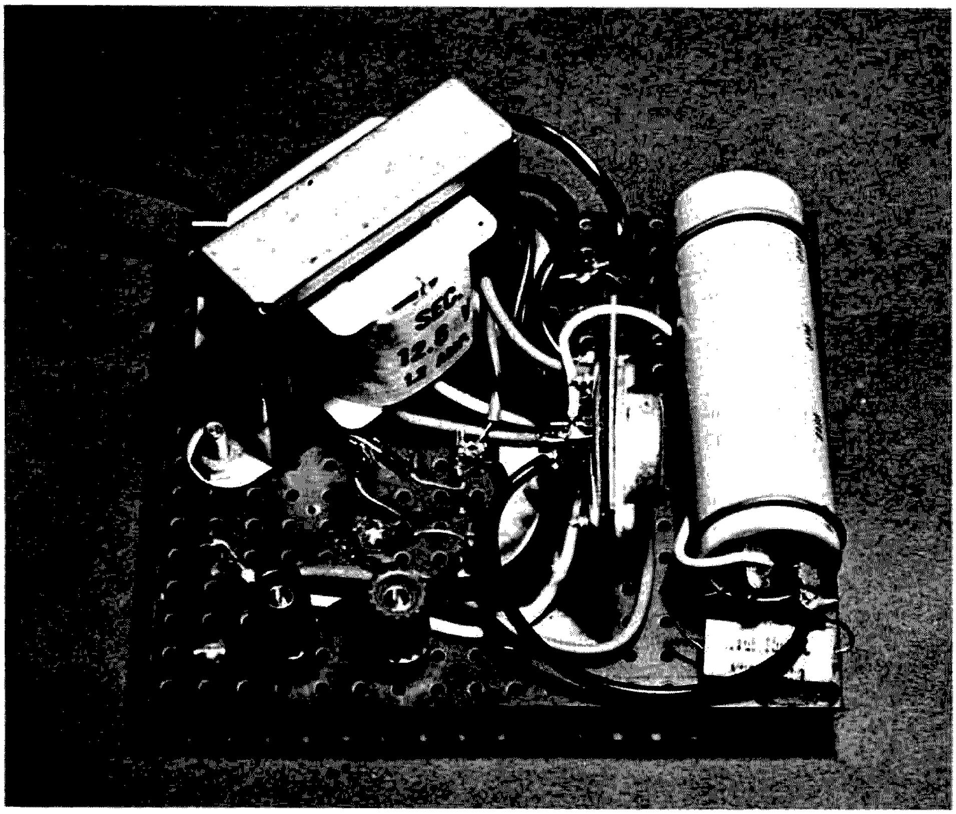
either. The upper limit is almost always 35 volts, except in some of those regulators with a high output voltage. For example, the uA7824 will take an input of up to 40 volts, but the other units in the uA7800 series (and the LM309) are limited to 35 volts. This figure includes *peak* ripple voltage. If the input exceeds the absolute maximum input rating, *permanent damage may result.*

There is another reason for keeping the input voltage as low as possible. The dissipation of the devices in the T0-3 or T0-220 packages must be limited to around 5 to 10 Watts, depending upon heat sink efficiency. (The LM309H, in its T0-5 metal can package, is limited to around 1 or 2 Watts power dissipation.) In this case, exceeding the junction temperature limit, for whatever reason, will only trigger the internal protective features – thermal shutdown and current limiting – causing no permanent damage. This is especially important if you want to draw a full Ampere from the supply. Although the dissipation capacity is still a function of heat sink efficiency, 20 Watts is the absolute maximum dissipation regardless of how much heat you remove from the case.

For these reasons I have included points, labeled D (for dissipation limit), on the graphs in Fig. 3. If you want to draw high currents from the IC, use a transformer voltage to the left of (above) points D and attach the regulator to an adequate heat sink with liberally applied silicone grease. The Signetics LM309 data sheet indicates that a typical commercial heat sink, the Wakefield 680-75, should be sufficient to allow the T0-3 package of the LM309K to dissipate from 5 to 7 Watts at room temperature before thermal shutdown is triggered. Use this as a guideline for determining your own heat sink requirements. Keep in mind that my placement of the dissipation limits in Fig. 3 is in no way absolute. Dissipation capacity is very dependent upon heat sink size and efficiency. Simple experimentation should be used to determine what size is needed for your specific application.

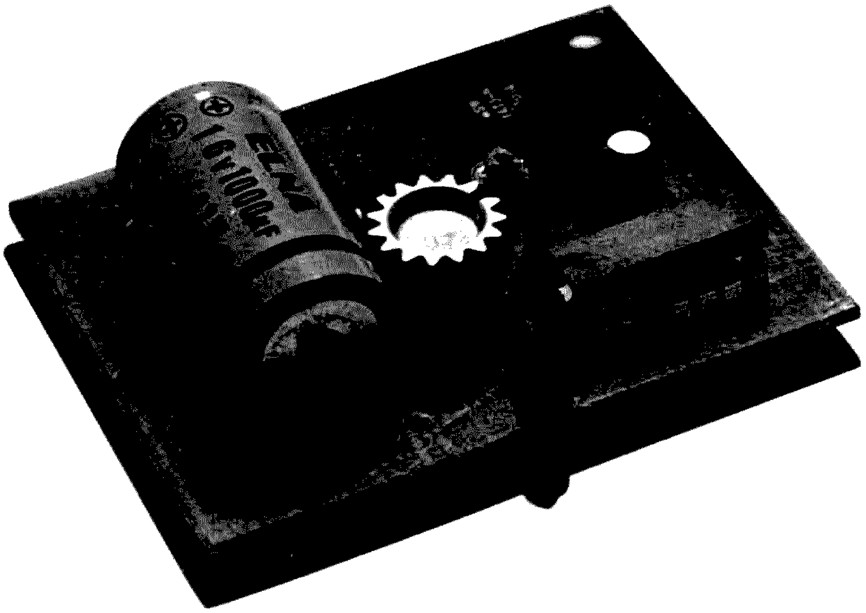
Refer to the base diagrams in Fig. 5 for finding the pin connections of the T0-5 metal can, T0-3 metal power, and the T0-220 plastic power packages. Follow normal wiring procedures, with no other special precautions except to make sure that you use large enough wire for the current you intend to draw.



This breadboarded supply was assembled with an LM309K for use in testing TTL circuits.

Design Calculations

For those of you who want to apply my design procedures to other three terminal regulators, or just simply want to know a little of the theory behind this shortened design method, here are all the necessary



Here is an example of an on-card regulator using the LM309H. The circuit is a T.TL heads-tails game, taking its power from a 9 volt battery.

calculations and a little on why they are used:

You do not get exactly 12.6 volts dc from a 12.6 volt transformer. Nor do you get 6.3; in fact, there is no such easy one-to-one relationship. Rather, you get a fluctuating dc waveform whose amplitude varies all the way from zero to a peak value of $\sqrt{2}$ (or about 1.414) times the transformer voltage.

As you increase the size of the filter capacitor, the ripple stabilizes. The waveform approaches an inverse sawtooth — an almost vertical charge time, followed by a nearly steady linear discharge rate, all repeating every 8.333 milliseconds (cycling at 120 Hertz). The peak value of the waveform remains where it was, but the amount of ripple subtracted from it decreases. Approximating a sawtooth will be close enough for our purposes.

Since specific transformer voltages are a lot easier to come by than are capacitor sizes (especially if you rewind them yourself — but that's another whole story), we will calculate the necessary transformer size needed with a given capacitor. Let's start by taking that capacitor size and calculating its ripple per given current drain:

$$V_r = \frac{8I}{C}$$

where V_r = peak-to-peak ripple voltage, I = current drain in mA, and C = filter capacitance in uF.

We now have the amount of ripple, the diode drop, and the dropout voltage of our IC regulator. The sum of these voltages equals our minimum necessary peak transformer value. The *minimum* rms voltage that we can use therefore is:

$$V_t = (1.414)\,(V_d + V_r + 1.3)$$

where V_t = transformer voltage, volts center-tapped (rms), V_d = regulator dropout voltage (usually 2 + V_{out}), and V_r = the ripple voltage we calculated above.

Since this equation is for use with a center-tapped transformer and a full wave rectifier, here is a modified formula to use for Fig. 2's bridge. It is not simply half of the full wave value, so use this modified formula instead of trying to work it out of the other one:

$$V_t = (.707)\,(V_d + V_r + 2.6)$$

where all variable names are the same as before.

If you are using other rectifiers and have more accurate data on them, you can insert your diodes' forward drop in place of the 1.3 and 2.6 that I use for 1N4000 series rectifiers. Remember that, whatever the *average* current, the peak value is much higher at specific instances. Currents above ten Amperes can be in a one Amp power supply! Keep this in mind if you calculate your own rectifiers' forward drop.

Round up your final answer. This will incorporate a safety margin to allow for component tolerances and line voltage fluctuations. A ten or twenty percent round up margin could safely be used, providing that you do not approach the absolute maximum input ratings of your device. Your final calculation should be a check to make certain that the instantaneous voltage, with the actual component values you have decided to use, never exceeds the capacitor or regulator input ratings. When you round up, all that you in fact are doing is improving the line regulation at only a slight trade-off in size and efficiency.

Device Availability

The LM309 regulator (both the H and K package styles) has been designated to be worst case 7400 TTL compatible. Barring thermal shutdown or current limiting, their output voltage will never deviate outside the 4.75 to 5.25 volt range that 7400 TTL logic requires — even counting line, load, and thermal regulation summed worst case.

The LM309H is therefore a prime candidate for on-card regulators for logic circuits needing less than 200 mA — and it is in fact somewhat unique in this respect. The larger package styles, although still small enough for PC board mounting, are more conducive to chassis mounting.

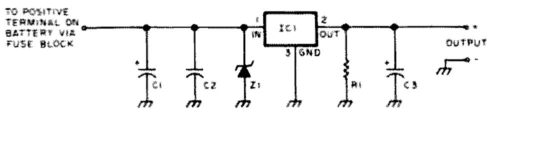


Fig. 4. This is a supply tailored for use in the transient-prone environment of a car. Zener Z1 can be anywhere from around 24 to 30 volts. All other parts are as in Figs. 1 and 2.

The LM309 is by far the most readily available of the many three terminal voltage regulators. For the sake of printing costs, some suppliers have omitted the LM prefix in their magazine advertisements. Others do not make obvious the distinction between the H and K case styles. Nevertheless, a good share of the surplus dealers that advertise in the back of this or any other experimenter-oriented electronics magazine do carry the LM309.

A different story exists concerning the uA7800 series. Even though here again some distributors have dropped the prefix in their advertisements for the sake of brevity, there simply are not as many firms carrying it. Careful reading of advertising, especially the literature sent by suppliers in response to Reader Service inquiries, will show you who sells what. There are some commercial and industrial suppliers who carry the units at prices only slightly higher than mail order surplus dealers. Surplus prices are all about the same, but since slight discrepancies do exist, shop around before you send anyone your money.

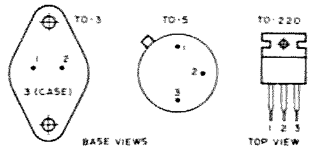

Fig. 5. Here are the pin connections for the TO-5 metal can, TO-3 metal power, and TO-220 plastic power packages.

There are quite a few regulators available that I have not mentioned here. Don't be afraid to try some of them. However, remember to make sure that you are buying a fixed voltage, three terminal voltage regulator integrated circuit. Some chips, such as the 723, are not three terminal devices, and they require a number of external components to adjust the output voltage and set the current limiting point. They have to be used with a much larger number of external components, in circuit whose design is much more involved than this. The giveaway should be that no specific output voltage is mentioned. If the device is advertised simply as a "monolithic voltage regulator," you can be pretty sure that it is a multiterminal unit. Some ads do not give a verbal description of the device, but just its number and price. You can cross-reference to other advertisements to figure out what the product is.

A series of regulators that you might be interested in – especially if you want to build a ±15 volt op amp supply – is the uA7900 series. They are negative voltage complements to the uA7800s. Availability is still somewhat limited, but hopefully it will improve shortly. Both series are produced in a wide range of output voltages, including a couple that I have not mentioned here. Again, check through the ads in the back of this magazine.

Make sure that, for any device you buy, you also obtain a set of the manufacturer's specification sheets and also, if possible, application notes. Originally the LM309 was produced by National Semiconductor and the uA7800 series by Fairchild, but quite a number of other manufacturers have since second-sourced them. So don't be too upset if you receive from a single distributor spec sheets and regulators with different manufacturers' names on them. There is enough industry-wide compatibility so that you need not worry about differences between manufacturers. (Actually, a more likely case would be to find no manufacturer's imprint at all on one or the other.) Hopefully, a little bit of reading through those data sheets and application notes will answer most of your questions.

There are external circuits, available from suppliers' and manufacturers' application notes, that can be used to make these regulators even more versatile. A typical circuit in this category is one enabling the output voltage to be set at different points, or even to be continuously adjustable. But since the main objective of this article is to introduce three terminal regulators in a relatively simple way, I will have to reserve discussion on them for the present time.

Three terminal regulators come into their own for the simple supplies. Usually, by the time you hang on all of the necessary parts to one of these three terminal units to achieve a specialized application, you find that you would have been better off by using a multiterminal device from the start. The 723 that I mentioned before is only one of a large number of these chips available.

I hope, even if you never actually use a three terminal IC regulator, that reading this article has given you a little knowledge about them and their use. If you have any specific questions you would like answered, or would like more explicit information concerning suppliers' names, feel free to write and ask me. (Please include a self-addressed, stamped envelope for my reply.) Maybe I won't know the answers to all of your questions, but hopefully I can at least refer your inquiries to someone who does. ■

Can An Indoor Antenna Work?

--making the best of a bad bargain

Many amateurs are forced to use indoor antennas on the HF bands either from their home QTH or while traveling. No form of indoor antenna is ever going to be as efficient a radiator as an outdoor antenna but there definitely are a few rules to be observed if one is going to achieve reasonable performance from an indoor antenna. In brief, these rules might be stated as:

1. The fact that an antenna is used indoors does not change basic antenna principles.
2. Choose an indoor location which provides minimum coupling loss to the outside.
3. Use an antenna form which is long enough to get power at least efficiently transferred from the transmitter into the antenna.

This article discusses each of the above rules in some detail and gives a number of examples to illustrate various indoor antenna ideas.

Radiation Characteristics

Many amateurs feel that, when an antenna is used indoors, its radiation characteristics can no longer follow the typical patterns shown in the various antenna manuals. It is true that, because of increased capacitive effects and coupling to the building structure, the wavelength formulas given in manuals do not always apply. But, the basic radiation patterns do not change greatly. For instance, a horizontal dipole still has its maximum radiation broadside to the line of the antenna. The same is true for an end feed wire unless it is several wavelengths long at the operating frequency, which normally would not be the case in an indoor location. Fig. 1 shows a bent half-wave antenna, end fed, used in a room. Maximum radiation is broadside to the antenna, or in this case in the direction bisecting the sides of the antenna. Obviously, if one forgets the "basics" and constructs an indoor antenna so it radiates maximum energy in a direction where few stations can be worked, one is wasting power in a situation where every bit of radiated power is precious.

Knowing the directional characteristics of loop antennas is particularly important since they are one of the most useful forms of indoor antenna. A large square loop (¼λ per side), such as the usual quad antenna element, has its maximum radiation perpendicular to the plane of the loop. If constructed as a closed loop, its terminal impedance is relatively low. For the loop described, it is about 80 Ohms. If the loop is fed at the bottom, the radiation is horizontally polarized. If fed at the side, the radiation becomes vertically polarized. Fig. 2(a) shows this type of loop. Many variations can be made on a full size loop by shaping it into different forms such as a triangle, by using loading coils to shorten the physical lengths needed and by more exotic shape deformations. One of the most interesting of the latter is shown in Fig. 3. It appeared in *QST* some time ago and good results were claimed for it. The radiation is vertically polarized and omni-directional. Supposedly, it could be turned around and used horizontally. With dimensions of only 1/10λ per side, it becomes feasible to construct it indoors (even on 40 meters) in large rooms.

Although large loops (even the compact version of Fig. 3) look attractive on paper, they become difficult to construct in reality. This is especially true if one wants to set up an antenna indoors for portable operation. A second

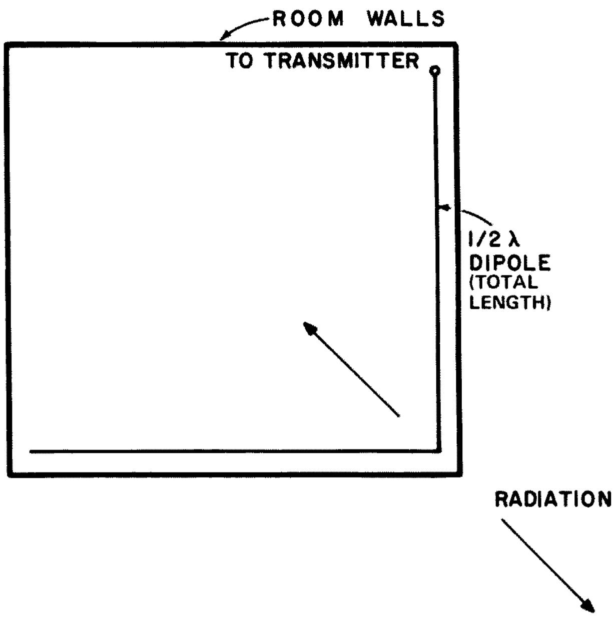

Fig. 1. A dipole antenna (1/2λ) retains its broadside radiation characteristic inside a room, whether center or end fed.

important class of loop antennas and the one most generally useful for indoor work is the $1/2\lambda$ loop ($1/8\lambda$ long per side). Such a loop can be considered as a half wave dipole antenna bent in the form of a loop. An important change in directional characteristics occurs, however. Maximum radiation is now in the plane of the loop *and* in the direction towards which the antenna is fed. This is shown in Fig. 2(b) for a loop which is "open" at its far end. The reason for "opening" the far end is to reduce the input impedance to about 50 Ohms. Otherwise, it would be in the order of several thousand Ohms and difficult to match. If the antenna is constructed vertically (diagonally across a room), its polarization will be vertical. If constructed horizontally (around the corners of a ceiling), its polarization will be horizontal. The direction of maximum radiation can be controlled by choosing at which end to feed the antenna.

The small loop adapts very well to usage in small to medium size rooms. By noting the dimensions of the room involved, one can quickly determine with a pocket calculator the lowest frequency band on which operation is feasible.

Operation on a second harmonic band is possible by shorting the far end of the loop and using it as a full size loop, but note how the directional properties of the antenna change! If the original $1/2\lambda$ loop used horizontally is used on a band where it becomes a 1λ loop, most of the radiation is straight up and down and useful only for extreme short skip contacts.

The next smaller class of loop is one having a total side length of $1/4\lambda$. Such a loop is similar to the loop of Fig. 2(b) except that capacitive loading is required at both the transmitter terminals and at the "open" terminals to bring the loop into resonance at the operating frequency. The capacitances needed depend upon the operating frequency but are 500-1500 uF at the transmitter end and 50-100 uF at the "open end" for 40/80 meter operation. A BC variable will suffice at the transmitter end but a wide-spaced variable is needed at the "open end." The capacitances are adjusted for minimum swr if a coax feedline is used or for best transmitter loading. The $1/4\lambda$ loop is a poor radiator – efficiency is only 8-10%. Yet, it may be the only usable antenna form if operation on a low frequency band such as 40 or 80 meters is necessary in a small room. Unlike the other larger loops, antennas where wire size is not critical, the efficiency of the $1/4\lambda$ loop is very much dependent upon using wire with low ohmic losses.

Indoor Locations

The idea of an outdoor antenna being located "as high as possible and as clear as possible" pretty well applies to the indoor antenna as well. Coaxial transmission line loss, even that of miniature coax such as RG-174, is quite low on the HF bands. It would be better to have an indoor antenna located as high as possible within a building, even with a long transmission line, rather than use an indoor antenna at a building level where it is shielded by other nearby buildings. In a private residence this usually means an attic location. In an apartment location one has to examine all the possibilities available since conditions will obviously vary quite widely. A disguised TV transmission line, for instance, might lead instead to a suitable loop antenna located inside or immediately around a roof level housing.

When choosing a portable indoor location one might

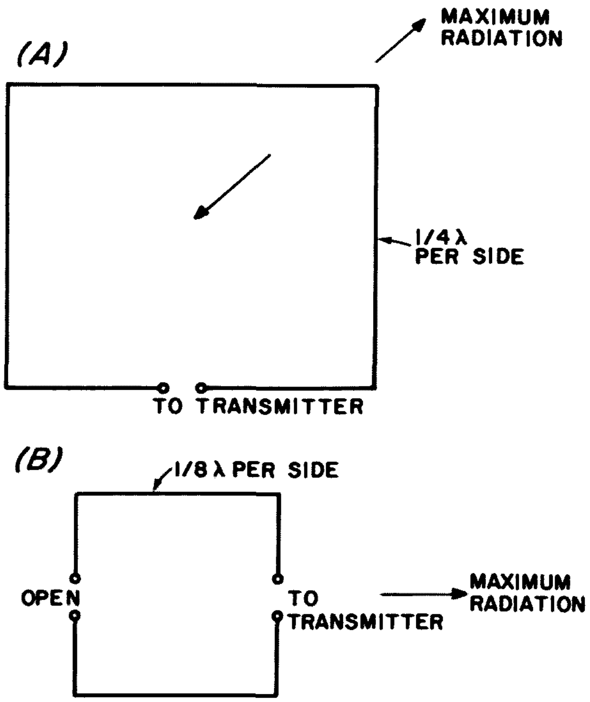

Fig. 2. The 1λ and $1/2\lambda$ loops are the most useful of indoor antenna forms. Both provide a good, direct match to coax line.

have a bit more choice of locations, such as when traveling on vacations. If any choice of building locations is possible, one of the principal rules is to avoid any steel-reinforced building locations. Such buildings will provide the same effect as though one were trying to work out of a screen-shielded room! Buildings can be examined for such construction by a variety of means. For instance, a simple compass can be used to examine walls for metal reinforcements. Sudden deflections at periodic intervals will indicate metal reinforcement as the compass is moved around closely against the wall. Most often, however, the basic nature of the building involved will provide the necessary clues. Any high-rise structure obviously has to be of metal-reinforced construction. Two or three story buildings may or may not be, even those of masonry construction. Wood frame buildings are obviously the most suitable, the only exception being to avoid being immediately under the roof of such a building if the roof is of tin or other metal. If one must work from a metal-reinforced building, one should try to be as high as possible in the building and in rooms with large glass areas.

Whatever indoor location is chosen, the antenna wire should be held a few inches away from the walls or molding if at all possible. The only exception concerns glass areas. If one is fortunate enough to be in a location with large glass areas, a good antenna construction material to consider is stainless steel tape. The tape can be placed directly on the glass and wires soldered to it, to join sections of an antenna and for connection of a transmission line.

Which Antenna Form to Use?

Working from an indoor location is a bad enough handicap, without having to lose transmitter power before it has a chance to be radiated. In other words, an antenna form should be used which will take and radiate as much of the available transmitter

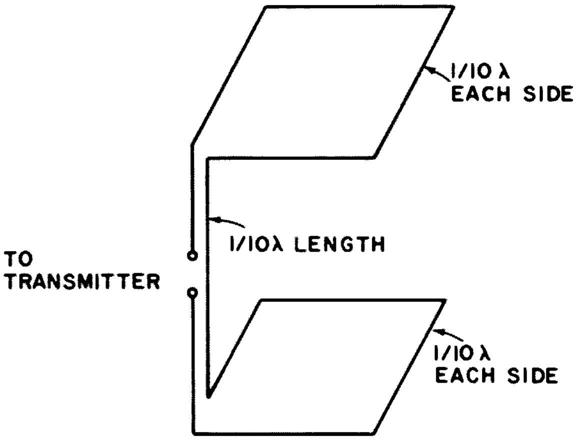

Fig. 3. An unusual method of folding a 1λ loop together.

power as possible without having that power burned up in ohmic losses in the antenna or antenna matching devices. In simple terms, put up as much antenna wire as feasible. A rule of thumb is not to use an antenna shorter than about 1/8λ. This would mean about 32' on 80 meters and would be a piece of wire which was being worked against some ground system such as the water pipes in a building. One can squeeze QSOs out of shorter antennas but it would be better to find some way to lengthen the indoor antenna by going through doorways between rooms or utilizing hallways where possible.

Progressing from the 1/8λ long wire one can go up to a 1/4λ or even 1/2λ long wire, all being worked against some ground connection. However, if at all feasible one should try to use a ground-independent antenna. The simplest is a dipole, either stretched out fully or formed into a "V" shape. Such an antenna can usually be used in attics on the higher frequency bands but the only solution in most cases for the lower frequency bands such as 40 and 80 meters is a loop antenna. The form of loop to aim for is the 1/2λ open-ended loop. Being a full 1/2λ long, its losses are low and it provides a convenient match to a transmission line or directly to a transmitter. Transmitters with adjustable pi-networks or similar networks can usually work into this antenna form without the need of additional antenna tuning devices. Being only about 8 foot on a side for 20 meters, it can be constructed in almost any room on that band or higher frequency bands. Being about 16 foot on a side for 40 meters means it can be accommodated vertically in only unusually nigh rooms. But, the diagonal run of many moderate size rooms will accommodate the horizontal legs of such a loop. In that case the vertical legs should be made as long as possible and the extra length made up by having a "U" fold in each vertical leg. Placed horizontally, such an antenna can be accommodated fully stretched out in larger size rooms. On 80 meters, a room would have to have unusual dimensions to accommodate a 1/2λ loop placed in any orientation and the only choice here would be the 1/4λ, tuned as previously described. Such an antenna has poor efficiency but still it will generally prove to be a better radiator than a 1/8 or even 1/4λ piece of wire worked against a lossy water pipe ground. ■

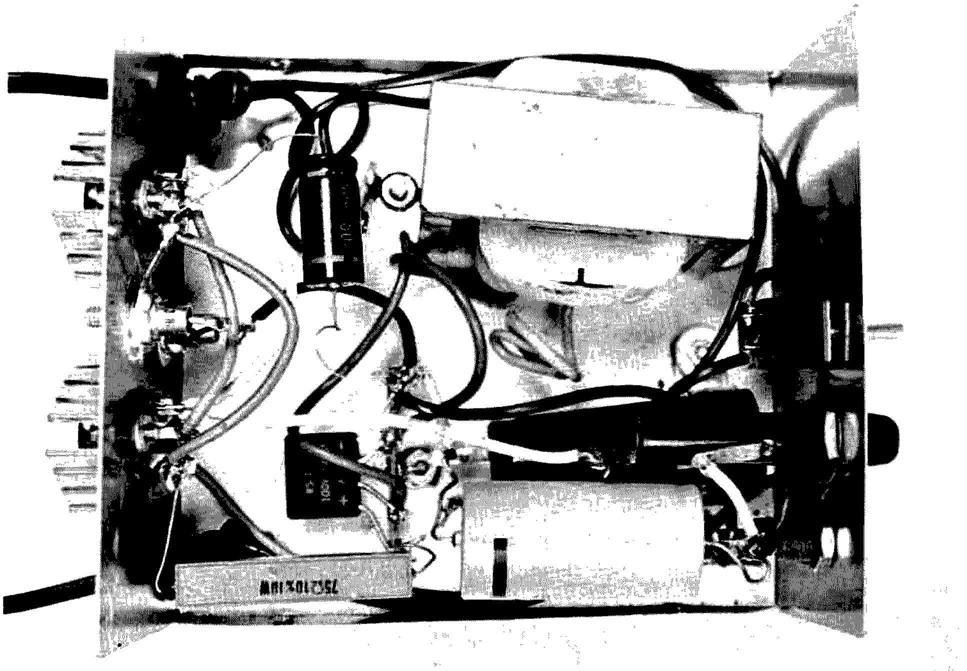
12 Inexpensive Volts for Your Base Station

--parts right out of your local Radio Shack

The two 12 volt power supplies use the same circuit. Meters were added to the version on the right to monitor the voltage and current.



Parts layout is not critical. The cabinet louvers are kept in the rear to aid in cooling Q1 and Q2.

The purchase of a new two meter FM rig a few months ago rekindled my interest in ham radio. My ham activity had fallen to an all-time low, but the FM rig helped me rediscover many of my old ham buddies who had already gone the two meter route. It also helped me discover several other things, among them the rapid advancement the state of the art had taken during my absence from the ham bands.

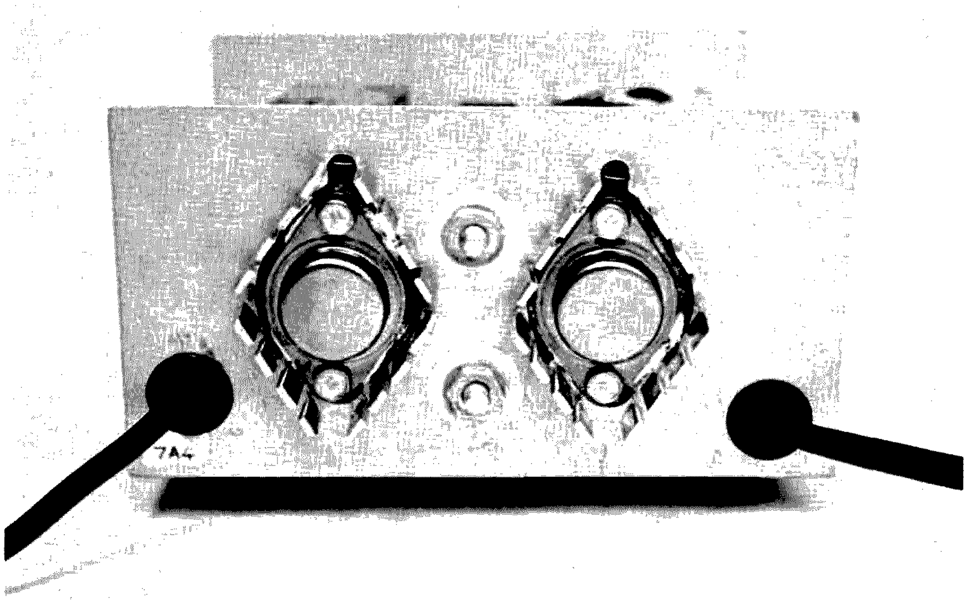
My FM rig worked great mobile; however, base operations were difficult due to the lack of an adequate power supply. The XYL took a dim view of the car battery and charger set up in the living room every time I wanted to monitor the machine from the easy chair. Battery acid and carpet do not a happy home make.

After reading the latest on regulated supplies, I decided to build one. They look simple and are, except for one small item; those nice little IC regulators are about as easy to find in my area as a pocket in a nudist camp. Not wanting a divorce, but desiring to work the rig at home, a solution had to be found. This little power supply was the result.

The circuit is very straightforward and simple. It is by no means original, but is a combination taken from several articles. The great thing about this power supply is that all the parts except the two 10 Watt zener diodes can be obtained from a local Radio Shack store. The entire supply should cost no more than $24.00 if all the parts are purchased new, and a less expensive cabinet or modest junk box will bring this down considerably.

I have built three of these supplies over the past couple of months and all have worked like a charm. The one on the right in the first photo is the main shack supply now in use. I added the meters to monitor voltage and current so the supply could be used for future projects. The small one on top of the Regency is the latest version. I wanted to run the rig at work, so this one was built.

Every part in this one was purchased at Radio Shack, except the 10 Watt zeners. These I bought from a local TV parts store, so they



The 10 Watt zener diodes are mounted with insulating mica washers on rear of chassis along with the power transistors. Ac line is on left, 12 volt output on right.

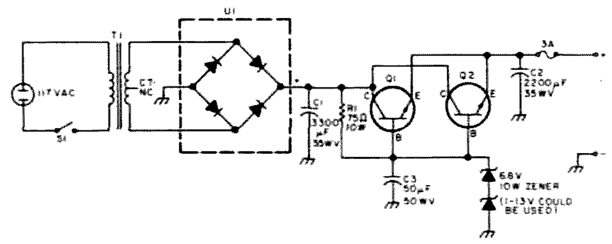


Fig. 1. Super simple 12 volt power supply. Q1, Q2 – 40 Watt power transistors, Radio Shack 276-592; T-1 – 12.6 V, 3 Amps, Radio Shack 273-1510; U1 – full wave bridge rectifier, 100 V, 6 Amps, Radio Shack 276-1171; cabinet – 5¼" x 3" x 5-7/8", Radio Shack 270-253.

should present no problem for anyone wishing to duplicate this supply.

Parts layout is not critical. The only suggestion I would make is to use a bus line for the negative voltage instead of a common chassis ground. This way a stray screwdriver from the case of Q1 or Q2 to the chassis will not short the transistors. The 40 Watt power transistors come 4 to a package. I had to do a bit of experimenting to find a pair that match, but at 30¢ each this is a minor problem. The rear chassis panel works fine as a heat sink; however, for added cooling I added the small heat sinks shown.

All in all, this little supply works great, looks good and is easy and economical to build. The regulation for the HR2B in the 15 Watt mode is less than ½ volt at 2.8 Amps. I have used this supply with other rigs such as the ICOM IC22A and other ten Watt rigs and the voltage drop has been less than ¼ volt. ■

Fig. 1. Typical receiver schematic.

A Test Lab Bonanza -- Free!

--using a transistor radio

Just about everyone needs more test equipment, or easier ways to use the test equipment he already has. Just about everyone has an old radio sitting around and this can provide the needed test equipment. You merely need to make the proper modifications to the radio, then know how to apply the resultant piece of test gear. Here are some modifications which will allow you to add a mess of handy test equipment to your shop, and still leave your old transistor radio in working order. The finished device will be everything from a speaker subber to a transistor checker, and will still provide your favorite news or music while just sitting on the bench.

The first consideration is what to do about packaging the radio. You may decide to leave the radio intact and add plugs and jacks of your choice in the radio cabinet. You could run leads out from the radio cabinet and put the plugs, jacks, and switches on a minibox. Or you could package the radio complete with modifications in the box of your choice. No matter what the package you choose, be sure to decide on plugs and jacks that you already have around so you don't make all your test leads obsolete. The diagrams in this article show the use of phone jacks, but you could just as well use banana jacks or whatever. Fig. 1 shows a typical radio schematic. Some

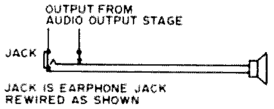

Fig. 2. Using the radio as a substitute speaker. You may wish to add a jack as shown while retaining the original earphone jack on the unit.

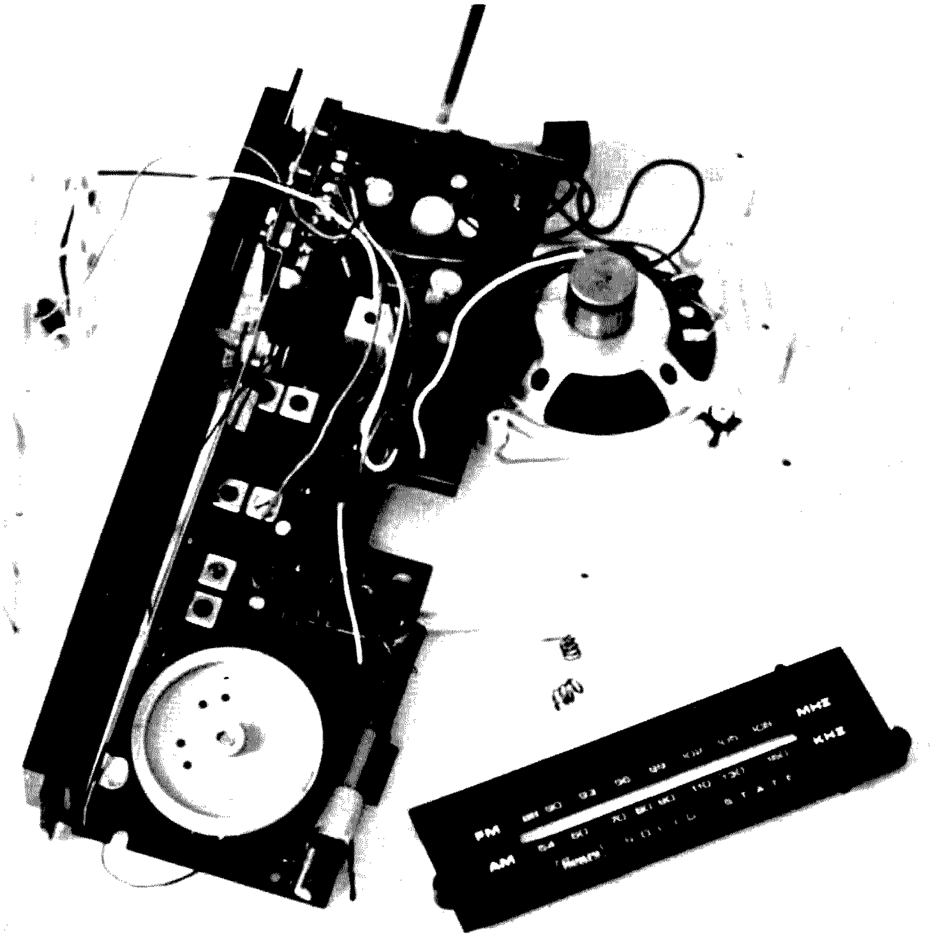
will differ, especially in part values, but the stages are essentially the same as the one shown. At least this diagram is helpful in locating where to put the modifications in your particular radio. You may add any or all the modifications to make a speaker subber, power supply, audio oscillator, signal injector, transistor checker, alignment generator, or weather receiver.

Speaker Subber

This is the simplest modification. You may add a plug as shown in Fig. 2 or you may modify the earphone jack already on many radios. When a phone plug is plugged in, the speaker is automatically disconnected. A pair of alligator clips on the end of the leads will allow you to connect to almost any source.

Power Supply

Whether your radio is battery or ac power, it will give you an easy source of 9-12 volts dc depending on the radio. All this without tying up the main power supply in your shop. When you are using the other radio circuits to check out a radio or experimenting with a circuit on the bench, the radio power supply will run both the test equipment and the radio or circuit under test. Fig. 3 shows some of the suggested modifications for both battery and ac power supplies. In Fig. 3(c) a transistor is used as a voltage source to provide variable voltage outputs from the



Here is a typical small radio undergoing transformation into a VHF receiver, one of the many applications described in the text. Add any or all to make your radio a handy piece of test equipment and still use it for a radio when it is not working for you. Note the coils in photo; these are the original FM coils removed for the frequency conversion described in the text.

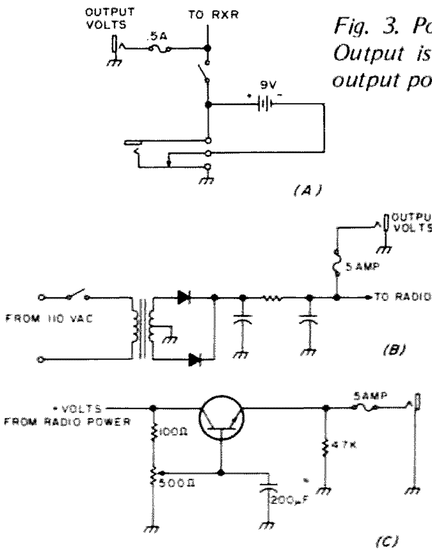


Fig. 3. Power supply circuits. (a) Simple battery supply. (b) Output is taken from an ac supply. (c) Continuously variable output power supply.

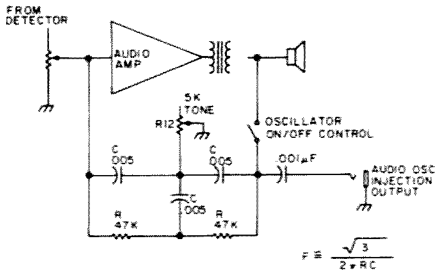

Fig. 4. Audio oscillator. May be used as an audio signal generator, code practice oscillator, etc. Values shown are for approximately 1 kHz; use formula for other frequencies.

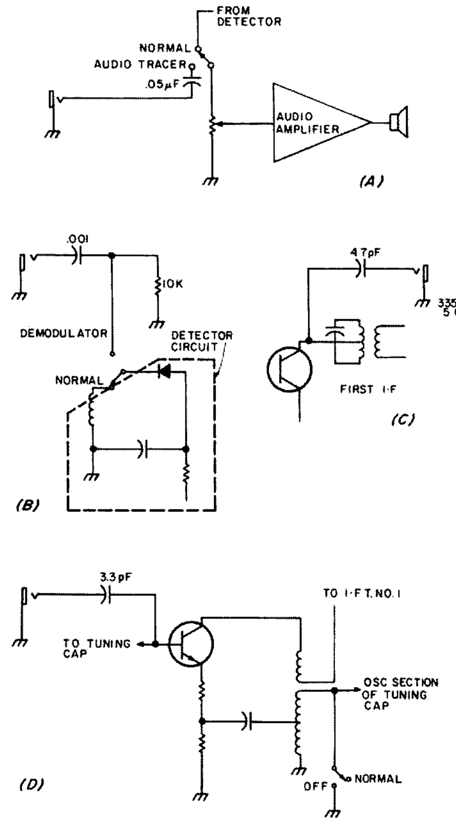

Fig. 5. Signal tracers. (a) Switch permits use as audio signal tracer. (b) The input is applied to the detector for use as a demodulator. (c) I-f injection for 455 kHz. (d) Oscillator is disabled to allow injection of oscillator from another set to test its operation. With switch at normal, radio can be tuned to detect 1600 kHz i-fs.

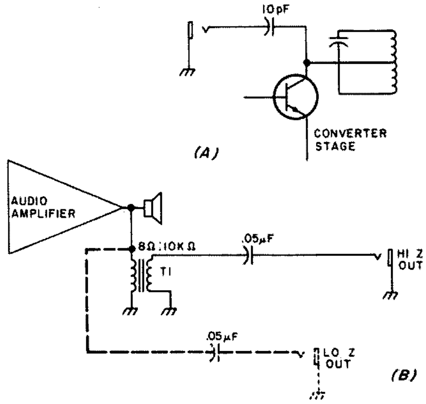

Fig. 6. Signal injectors. (a) The 455 kHz output from the converter can be injected in various i-f stages to check out their operation. (b) Addition of an impedance matching transformer for an audio signal injector with high output impedance. Dotted lines show alternate connection.

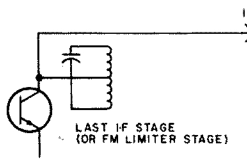

Fig. 7. This configuration will act as a fairly accurate i-f alignment generator. Since the output is from the last stage at the i-f, you have the advantage of the narrowing from all the tuned circuits at the intermediate frequency.

radio supply. You cannot ruin the pass transistor because you cannot short circuit the transistor circuit. If you have a battery level indicator on your radio, it may be calibrated and used as a voltage indicator. By adding a resistor network and range switch in place of the potentiometer, you can have discrete voltage outputs such as 1.5, 5.9, etc.

Audio Oscillator

Fig. 4 gives the modifications which make an audio oscillator. The result can be used as a code practice oscillator, test oscillator, audible continuity checker, or audio signal injector. The tone control provides some measure of control of the basic oscillator frequency.

Signal Tracer

The radio will work as several different tracers. The most obvious use is shown in Fig. 5(a), an audio signal tracer. Injecting a signal at the detector as shown in Fig. 5(b) yields an rf demodulator tracer. If you inject a signal into the i-f as shown in Fig. 5(c), you have a 455 kHz tuned tracer (or 10.7 MHz if the radio has FM) for use with standard i-fs. If you allow disabling the oscillator as in 5(d), you can inject another radio's oscillator signal to test the oscillator section of the other radio. Just inject the local oscillator from the radio being serviced, juggle the dial on both radios, and if you can pick up signals, the oscillator in the other radio is working. The same method could be used for FM systems; in that case, couple the oscillator signal to the FM converter stage through a gimmick of about 7 twists of hookup wire connected in the same place on the FM converter stage. You will have to add a switch to disable the oscillator as shown on the AM converter circuit. For the AM radio, the oscillator injection point also serves as a point to inject rf from a system that uses 1600 kHz i-fs by letting the oscillator run and tuning the radio to 1600 kHz.

Signal Injector

The output of the converter taken from the point shown in Fig. 6(a) provides a 455 kHz signal for checking the i-f of a radio. (An equivalent point on the FM converter provides 10.7 MHz signals.) Tune the radio to a station and the 455 kHz output will be the signal transmitted from that station. Fig. 6(b) shows the connection for injecting audio signals; just tune in a station and use its audio to check out the audio circuits under test.

Alignment Generator

In Fig. 7 the output from the i-f is taken after it has gone through several stages of i-f amplification. Since this signal has the benefit of the several stages of selectivity, the i-f output signal can be used as a source of accurate 455 kHz (or 10.7 MHz) assuming the radio has been accurately aligned. Merely align the radio as one of the steps to making it into a piece of test equipment. Signals tuned in on the radio will be translated to their equivalent

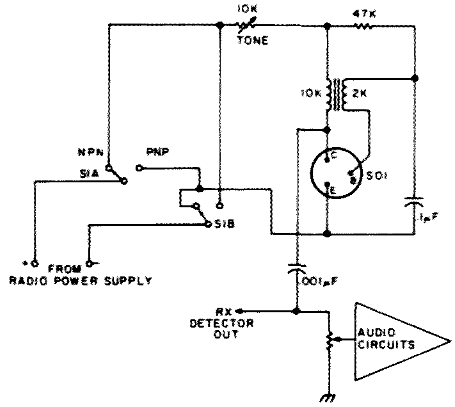

Fig. 8. Go-No Go transistor checker will work with silicon or germanium types with reasonable HFEs. Use a good unit for checkout; if circuit fails to oscillate, reverse either the primary or secondary connections. A good transistor will produce a tone in the speaker. You may wish to use clip leads in place of a socket.

i-f frequency and can be used as alignment signals.

Transistor Checker

Fig. 8 shows an outboard circuit added to the radio to allow in or out of circuit transistor checking. If the transistor under test will oscillate, it is generally good. This is a fairly accurate check in or out of circuit. Another simpler tester can be fabricated by merely replacing one of the transistors in the radio with a socket. When a transistor close to the type you are replacing it with is put in the socket, the radio should work. This test is only accurate for the NPN or PNP transistor type being replaced, and will only work with silicon or germanium types depending on what the radio has originally. This simple tester will not allow in-circuit checks at all, but the radio will operate normally as soon as the original transistor is placed in its socket.

Band Opening Monitor

Fig. 9 shows the schematic of a citizens band converter that works into the 455 kHz i-f of an AM radio. You may shudder at the thought of listening to the citizens band, but it sure is a good band opening monitoring device. Just buy a crystal for channel 10 and you will rejoice when the DX comes rolling in. Crystals are available at your handy Radio Shack store for a few pennies. Just don't let 'em worry you with that stuff about what model transceiver the crystal is for . . . any one will do.

Commercial FM Receiver

If your radio has FM, it can be modified to make a receiver that will pick up commercial business-band FM signals such as police, fire, public service, weather, etc. Some find the idea of listening to these signals more appealing than music when the radio is resting on the bench. Begin the modification by changing the oscillator coil. Reduce the number of turns by 1/3, then bring it on frequency by adjusting the spacing of the turns and the trimmer capacitor on the radio. If you can't measure the oscillator frequency with a grid-dip meter or equivalent, use a TV tuned to channel 7. Watch the TV as you tune the oscillator; when you can see and hear a signal on the TV, the oscillator is set around 175 MHz. The radio will now tune around 185 MHz or 165 MHz, depending on the resonant frequency of the circuits in the rf amp and mixer stages. Reduce the number of turns in the rf stage and the mixer by the same factor as the oscillator coil. Tune them in by adjusting the spacing and by resetting the trimmers on the tuning capacitor. Final tuneup should come while listening to a signal.

Now that the radio is completely modified, it will serve you well as a radio as well as a handy test jig ideal for servicing transistor radios. The unit is also perfect for the experimenter who may need to use one or all its functions in checking out breadboard circuits. Once you master use of all its possibilities, it will prove as handy on your bench as your VOM. ■

Protect Your VHF Converter

--with a novel antenna relay

Today's modern VHF receiving converters are superior in many respects to their older tube conterparts. Their noise figures are lower, gain is usually higher, power consumption is down, and because they are solid state, they lend themselves easily to portable operation.

They have one shortcoming: They must be protected against transients from the transmitter. This is especially true of converters with MOSFET front ends.

The standard antenna changeover relay may not be fast enough. The transmitter should be turned on after the antenna has been switched and should be turned off before the antenna has been switched back for maximum protection. Of course, the changeover relay should provide a high degree of isolation between transmitter and receiver ports.

Fig. 1 illustrates such a system. The theory of operation for the system follows (refer to Fig. 1).

When the push-to-talk switch S1 is closed, relay RY1 is energized. This energizes relay RY2 and partially completes the circuit that will allow relay RY3 to be energized. This allows the antenna to be switched and the receiver muted. Closure of RY2 completes the circuit for RY3, energizing it and allowing the transmitter to be keyed.

When switch S1 is opened, RY1 opens, opening the circuit for RY2 and RY3. Relay RY3 opens, turning off transmitter power, but RY2 is held in by the charged capacitor C1. This keeps the antenna connected to the transmitter until all output from the transmitter has ceased.

The relay RY2 can be a Dow Key 12 V relay with outboard DPDT contacts. If this relay is used, the other relays should be 12 V also. Capacitor C1 should be selected to operate with the coil impedance of RY2. (My system used a 300 uF capacitor.) Diodes D1 and D2 serve to short the transient developed by the collapsing field of RY1 and RY2 after they have been turned off.

Although the circuit may look involved, it does offer good protection for solid state VHF converters. ■

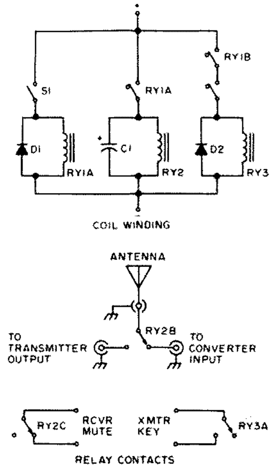

Fig. 1.

It all started through the courtesy of K3CPG. He had heard that some teletype page printers were to become available through the time-honored grapevine. With the expenditure of a bit of physical energy, our home was adorned with a large black box nicely mounted on its own pedestal. Having never worked with teletype, I was given the short course by WA3RMA.

The first order of business was not too tough: Build a loop supply. The result is diagrammed in Fig. 1. Do not omit the 1.0 uF capacitor and do not significantly increase its value. The teletype machine seems to be the home of some rather nasty electrical noises, when running, and the function of this capacitor is to keep those electrical disturbances from getting into your receiver and your terminal unit.

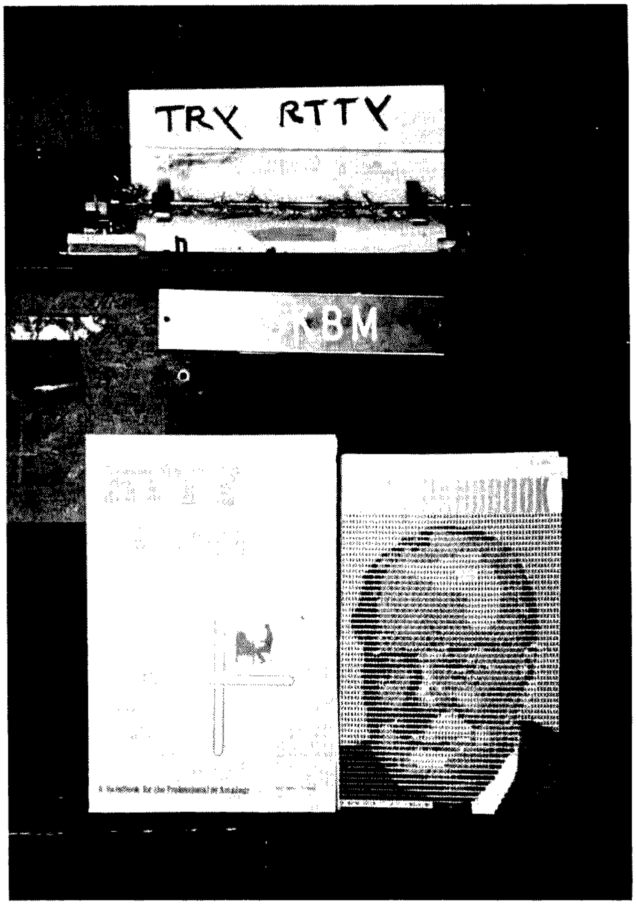
When I first completed the loop supply, I put a key in series with it. With the machine running I was able, by keying, to generate letters and numbers in random fashion. This did nothing but prove to me that the loop supply and the machine were functioning in some fashion.

The next step, again taken with the help of WA3RMA, was to test the machine using his TD or tape distributor. The RTTY magnet is plugged into J1 of the loop supply and J2 accepted the TD output. The sights and sounds of good copy coming from the punched tape of the TD let me know that the machine was in proper adjustment.

This led to the next step, namely building a TU or terminal unit that would take the output of my receiver or tape recorder and let the machine do its stuff.

I had purchased copies of two books: *Teletype from A to Z* by Durward J. Tucker and the *RTTY Handbook* by Wayne Green. These volumes are excellent, and while they do have some duplication of material, they are complementary and well worth having in your technical library.

Having enough printed matter to completely avoid re-inventing the wheel, I was, however, determined to try my hand at designing a TU.



The requirements were low cost, simplicity, solid state, and the capability of copying wide shift and narrow shift. Early in the design I decided to try copying on one tone only, choosing the space tone. Fig.

Ridiculously Simple RTTY System

-- get on the air in one day

Allan S. Joffe W3KBM

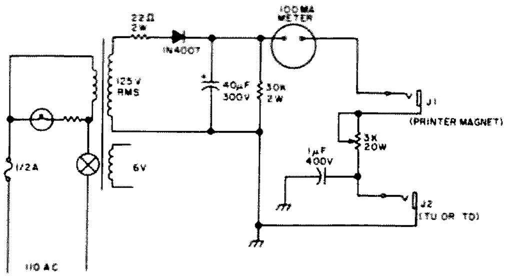

Fig. 1. RTTY loop supply. Transformer: Stancor PA-8421. Adjust 3k resistor so loop current runs about 60 mA, steady state. Note: If you use a metal panel, J-1 must be insulated from the panel.

2 shows the schematic of the finished product.

The input sensitivity is such that about 150 millivolts will produce RTTY copy. However, it is best to use enough input to take advantage of the clipping effect of the diodes shown as part of the input circuit to counter the effects of fading on the low frequency bands.

The next element in line is the audio filter that selects the space tone from the RTTY signal and also insulates the unit from QRN and other interference. This filter owes most of its form to an excellent article by Courtney Hall (September 1975 *Ham Radio*).

In his article, he indicated trouble with oscillation at certain filter settings and boy, he was right. I managed to cure the problem with the 0.001 capacitor that goes from the junction of the 1500 Ohm resistor and one end of the tuning pot. This capacitor to ground made the filter circuit stable at all settings. The unstable portion of the tuning range was the low frequency end, and I did do enough playing with different values of capacity to determine that significantly more than the 0.001 made other troubles, so stay close to this value.

The tuning pot is a 5k linear which will allow the filter to tune from 1500 Hz at the low end to just a bit over 3000 Hz at the high end.

The 1500 Ohm resistor connected to one end of the pot has the greatest effect on tuning range. The 150k resistor connected to the other end of the pot mainly affects the sharpness of the filter peak. Here again these values were diddled with enough to know that they are "on the money."

The filter is connected in the feedback loop of IC1 which is an 8 pin minidip 741. Curiosity impelled me to see if various ICs of the same type would significantly vary the filter tuning. The average of five different ICs showed no significant shift in either frequency or peak as the case may be.

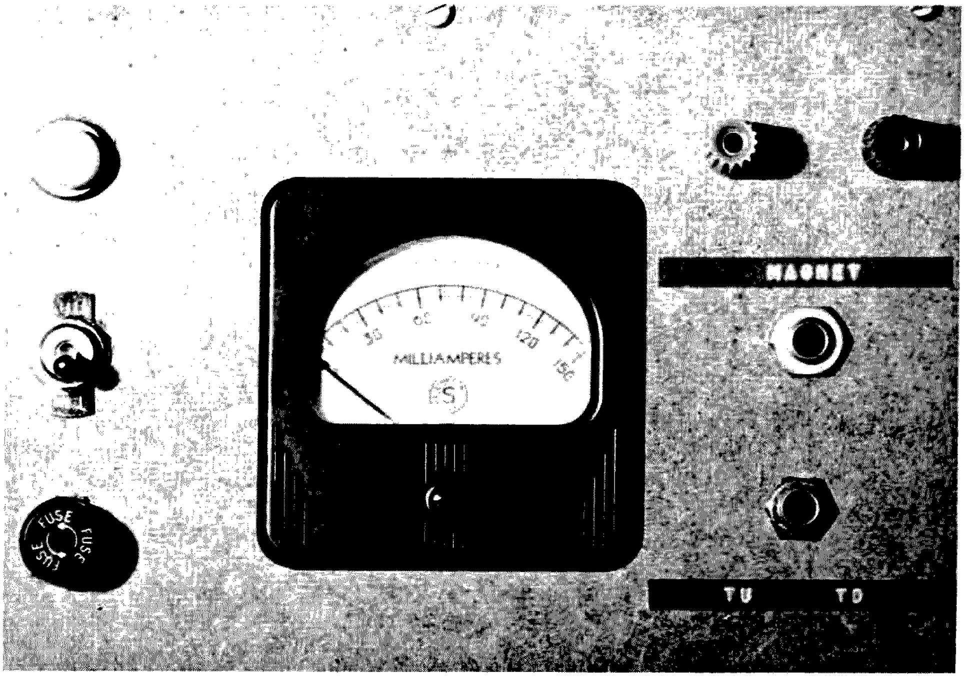
The output of this IC is rectified by the diode, and the rectified voltage is developed across the 15k resistor from diode to ground. Notice that the polarity is negative. In passing, I will note that in the finished unit I have tried bypassing this resistor with a small capacitor ranging up to 0.05 uF with indifferent results. You can try this yourself with the understanding that as you approach 0.05 uF, the circuit starts to lose its immunity to QRN of the static random impulse variety.

Before we leave this area of the circuit, let's examine the meter which is connected across the 15k diode load. This is a very useful item as it serves as a tuning meter for the TU. The meter is multiplied (50 microamp basic scale) so that it becomes a three volt full scale dc meter. With a RTTY signal applied to the TU, the tuning pot is varied until the meter indicates that the filter is tuned to the desired tone. In normal operation, the meter will show about 1½ to two volts. The reading will vary with the incoming transmission characters, with fading of signals, etc. Do not omit this feature unless you enjoy headaches with your RTTY.

Up to this point, we have selectively filtered the RTTY signal, limited it to take care of input level variations, within reason, and supplied a tuning indicator. The next step concerns IC2, which is another 8 pin minidip 741 op amp.

This stage is used as a dc comparator. A negative polarity reference voltage of about 0.75 volts is provided by the voltage divider which goes between the minus terminal of the split voltage power supply and ground. When this voltage is applied to the designated input of the comparator, the output is highly positive on pin 6 of the IC. The other input of the IC is connected to the rectified signal output of the previous stage which, as has been stated before, is also negative in polarity.

When a RTTY signal that can pass through the filter is present, and if its value causes the voltage applied to IC2 input to *exceed* the reference voltage from the divider, the output of IC2 will imme-



diately swing to ground or even a small amount negative.

The output of IC2 is directly coupled to the base of Q1. When IC2 output is positive, Q1 is biased full on and current will flow in the printer magnet. When the output of IC2 is at ground or slightly negative, Q1 has no base drive and no current flows in the printer magnet. Thus Q1 acts as a switch turning the printer magnet current on and off with the incoming RTTY signal, hopefully creating our objective of solid RTTY copy.

Q1 deserves a bit of special attention. It is an MJE-340 which is rated at some 300 volts and was obtained from SD sales through an ad in this magazine. Notice that there is a diode in series with the collector. This serves to protect the transistor from high voltage negative transients that may be present when the current in the printer magnet decays upon opening. To heat sink or not to heat sink is an open question. When the unit was under development, I had it running for some 20 minutes with RTTY going through it, and the MJE-340 remained quite comfortable, thermally speaking. In the final version, I chickened out and attached a symbolic heat sink of thin sheet copper approximately 6 cm square in area.

That about wraps up the unit but still leaves some explaining to do. For wide shift RTTY, the space tone which we are using to produce copy is 2975 Hz. The other tone you hear is the mark tone, and for wide shift it is 850 Hz below the space tone, or 2125 Hz. When the RTTY signal is applied to the TU, we tune the frequency pot so that the space tone is accepted by the system. The effect of the mark tone is acquired by indirection. Hopefully, since the RTTY signal is composed of mark and space tones, our TU will respond faithfully to the presence of space tones and by doing essentially nothing will indicate to the RTTY machine where the mark tones are in the transmitted characters. This is what I mean by "mark by indirection." This has one added plus. When no signal at all is present, the machine will run "closed." This is the equivalent of a simple "mark hold" circuit. Its additional virtue derives from the fact that when the machine is running "closed" it makes a lot less noise than when running "open," strictly because there is much less mechanical activity going on within its innards.

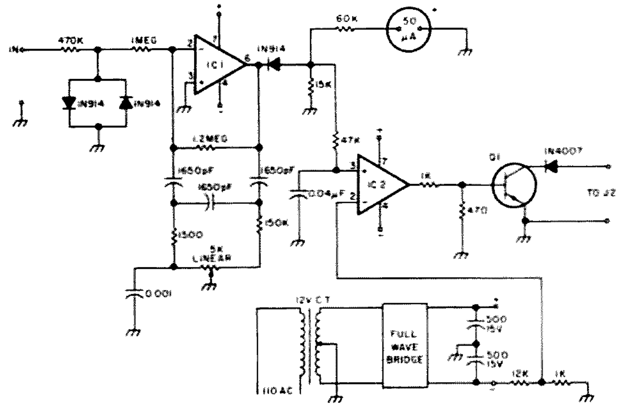


Fig. 2. RTTY TU. IC1, IC2 – 741 op amps; Q1 – MJE-340. All resistors ¼ W if wattage not indicated.

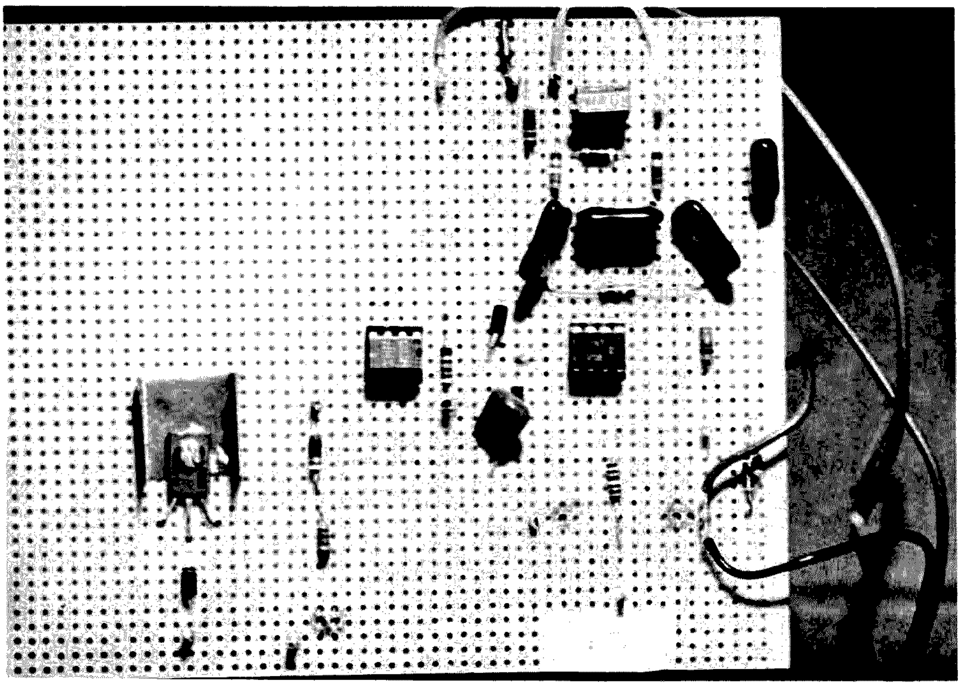
When receiving narrow shift RTTY, the mark tone is not changed, but the space tone usually becomes 2295 Hz which is only a 170 Hz separation. It is under narrow shift conditions that you can begin to appreciate just how good the simple audio filter really is (Table 1).

You are going to run into two different RTTY transmission types on the ham bands, FSK and AFSK. AFSK is the simpler mode to receive and will be found on six meters and two meters and possibly higher.

Basically, in AFSK, the RTTY machine at the sending end keys an audio oscillator to produce the two tones usually transmitted. This varying frequency audio signal is used to modulate the transmitter. At the receiving end you merely tune in the signal in the same manner as a voice transmission, apply it to the TU, and sit back and let the machine do its thing.

I said that AFSK is by far the simpler mode to receive for the following reasons. Most of us, as I am, are burdened with super selective receivers for the low bands where FSK is used. My receiver has a selectivity of about 2.1 kHz and there's no way in the world that I am going to be able to get a decent 2975 Hz audio signal through it. This is the reason that the audio filter has been designed to function effectively down to 1500 Hz. What you do is receive the signal just like any CW signal. In FSK, the transmitted carrier is actually shifted in frequency and arrives at your receiver just like a CW signal as far as sound coming out of



the audio system goes. Without the BFO on, it is just a series of clicks. Now, how do we solve the dilemma of getting a signal out of the receiver when I said that my receiver won't pass the signal, audiowise, due to the tight bandpass? Simple ... you just vary the tuning or the BFO until the generated audio beat tone is down within the tuning range of the audio filter in the TU.

The tuning meter greatly facilitates this process, and after several tries you readily get the feel of what sounds right. The procedure for wide shift or for narrow shift is the same. If your receiver is a wide band job, it will make the translation process unnecessary, but you will pay the penalty for lack of a narrow pass band, namely more interference from adjacent signals.

Using this TU, I have gotten very good copy from W1AW on their satellite transmissions which let one and all know what "Oscar" is up to. The transmissions I copied were aired on Sundays at 5 pm on a frequency of 3620 kHz. The first transmission used wide shift, and the same information was repeated after this using narrow shift. This is an excellent transmission to use for test copy as the signal is strong, clean and uses both shifts.

It is practical to copy a signal on a reasonably good reel to reel tape recorder. During the test period of the TU, I would feed the receiver both to the TU and the tape machine. The taped copy gave me a known signal to pump into the TU while changing parts values during the design. From experience, I can freely and sadly state that all tape machines running at a given speed, say 7½ IPS, really do not. Play the RTTY tape back on the same machine that it was made on, to avoid real grief.

Decibels	Frequency Hz	Voltage shown on tuning meter
±0	2295	1.50 volts
-3	2285	1.25 volts
-6	2275	0.75 volts
-11	2265	0.40 volts
-23	2255	0.10 volts
	2245	For these two frequencies, voltage
	2235	was too low for accurate reading.

Conditions of measurement: Enough voltage was applied at 2295 Hz to make tuning meter read 1.50 volts with filter peaked. Frequency was monitored by counter and varied in 10 Hz steps.

Table 1. Values showing effectiveness of filter when tuned for narrow shift. Space frequency is 2295 Hz.

If you enjoy suffering, try using a run of the mill cassette recorder.

For those inclined to put a scope on things they build, you should see nothing but nice clean square waves bouncing merrily at the base of Q1. It is the function of the 0.04 capacitor at the non-inverting input of IC2 to clean up any RTTY signal ripple. Do not increase the value of this capacitor. However, you can drop it down to an 0.03 with very little difference in effect.

You will notice after a bit that the rhythm and sound of your printer will tell you if all is well with the printing process. This is particularly true if the transmission is coming in from a punched tape. You will soon learn that any radical departure from that nice steady mechanical chuga chuga chuga means that something is amiss. Of course, if the transmission is manual, this is not true, particularly if a hunt and peck artist is at the other end of the circuit. ■

How to Catch a CBer

-- practical hints

Judging from the title of this article, your first thoughts were that someone finally wrote "An Elementary Guide to Catching and Prosecuting Your Local Bootleg Citizen Band Operator." He's that "good buddy" that is wiping out all your neighbors' boob-tubes with his 1 kilowatt linear and spreading hate and discontent throughout the whole area. I'm sorry to disappoint you, but this article is intended to help you catch those CBers who are just about ready to turn in their skip handles because they have had enough of the CB retailers' "big bonanza." This article is from an ex-CBer, ex-Novice, and almost a General Class ham's point of view on what to do to catch a new ham – or if you prefer, a CBer.

My background in CB runs the whole interest spectrum. I started as a legal call letters CBer, progressed through the "track down those lawbreakers" period, and finally ended up joining their ranks as the "Spook." After attending their social gatherings for a few months, I met the girl of my dreams and had the traditional CB wedding. One guest remarked that the church parking lot looked as if the fishing fleet had come in because of all the cars with CB antennas on them. Luckily, my marriage has lasted longer than my interest in CB. And that is why I turned to ham radio and away from the "good buddy" part of my life in 1972.

Somewhere in the scads of CB articles in the *Pop Electronics* magazines, I have read that the average life expectancy of a "good buddy" is 3 or 4 years. That's from when he first gets excited about CB until he no longer has any interest in it as a hobby or way of life.

During this time the average CBer buys a SSB base radio, 2 mobile AM rigs, a groundplane, tower, rotor, and beam antenna, plus a linear and all the extra goodies to make his station the talk of the town. This means the fellow can spend a couple of hundred or a couple of thousand dollars, but spend they do in a big way. Through this period of second mortgaging his house to buy CB equipment, the "good buddy" can usually be found at coffee breaks shooting the bull and trading QSL cards, going to CB jamborees hundreds or thousands

of miles away, and making himself known for miles around by yakking on the radio day and night. Then along comes about the fourth year and the CBer realizes that it's just no fun trying to fight the local "channel hog" for a break or trying to compete with the thousands of new CBers on his channel just to attempt to talk 15 miles. Even skip shooting is becoming impossible with these new fellows and their new linears in the local area. So the "good buddy" decides to sell his station for that camera equipment that he has always longed for, and his CB way of life ends.

Now this is the chance that ham radio clubs have been waiting for to pick up some new recruits. Hundreds of these "good buddies" have gotten to the point of selling out because of a general lack of interest and the enormous crowds since the CB boom of 1976 came along.

Of course, I am speaking of C. W. McCall's hit record "Convoy" (about the CBing truck drivers), television's "Movin' On" with those CB truckers Sonny and Will, and the country western and rock stations across the country that are giving CB rigs away by the bushel to promote the song. And then there are all the clubs: CB, custom vans, custom 4 wheelers, custom pickups, custom VWs, custom skateboards, custom motorcycles, custom 18 wheelers, custom motorhomes; and don't forget airplanes, hot air balloons, hang gliders, and the ever popular U.S.S. Enterprize "Star Trek" Space Communicators with twin warp sound for the kiddies. A quick analysis of the situation leads me to ask these vital questions: Is everybody in this country a "good buddy"? Does everyone drive a semi and say "negatory" and "10-4"? Is everybody from Oklahoma and what is bodacious?

Millions of people are "turning off" CB after long and illustrious careers (to buy camera equipment) because of the CB boom. With something like 500,000 CBers a month seeking FCC licenses, there just isn't any place for the old timers to go to have room to talk. Even the high channels above channel 23 are filling up with sidebanders and their funny Donald Duck talking. So the "good buddies" with their Yaesus, Trams, and Tempos try to use off channels, ham bands, or just give up and finally sell out completely. The reason always seems the same: all their friends are gone and the channels are too crowded to use.

So how do the hams attract all these CBers into their clubs? Let's find out how the average guy gets interested in CB in the first place.

The Neighborhood CBer

Most CBers are drawn in by the advertisements in the media, or by a friend or relative who shows the prospective CBer what fun it is to talk on his cute little radio, get these nifty QSL cards, and use a catchy little handle like "Spook" or "Li'l Goober." The neighborhood CBer takes him to a CB coffee break to meet other CBers, and later helps the new guy buy a rig, put up antennas, check swr, fill out applications and give him all the help he needs to get into the CB groove.

CB Coffee Breaks

Coffee breaks are family style get-togethers usually held at pizza parlors with food, beverage, a live country western band for dancing, drawings, and a meeting thrown in. The drawings and prizes are what bring the crowds to the breaks — the better the prizes, the bigger the crowd. Most of the money goes to buy more prizes, but any left over goes to the club to sponsor picnics, dances, or campouts. Family participation is really stressed with all sorts of kids' prizes, food or appliances for the wife, and lots of radio gear for the hubby. An awards ceremony usually follows with presentations such as Channel Hog Award, Rachet Jaw Award, Bucket Mouth Award, and the coveted All Mouth No Ears Alligator Awards. The CB family comes home with a full stomach after a fun evening with friends, and with a little luck, all sorts of prizes just for buying a few bucks worth of tickets. My wife and I have furnished our kitchen in this manner for years — sure saved us a bundle.

CB Jamborees

Jamborees are the big brothers of coffee breaks and are usually held at county or state fairgrounds. An individual or club rents the fairgrounds, then rents out sales space for business and controls the food concessions. The club has printed thousands of flyers which are carried or sent to other jamborees all over the country hoping to bring droves of CBers to this jamboree. And not wanting to be left out of the "big one," a typical "good buddy" packs up the family camper, and family and friends caravan a thousand miles for a weekend jamboree.

Jamborees are like big fairs with something for everyone. Activities at most jamborees are dealer displays, carnival, flea market, kids' games and rides, bed racing, country western dances, liquid refreshment, and the thrill of meeting all those other skip talkers eyeball to eyeball. Two full days of excitement with your friends in a party atmosphere for only the cost of parking your camper on the grounds with hookups and buying tickets for the thousands of dollars of prizes the jamboree has put up to

bring in the crowds. The family has a great time and the "good buddy" comes home with a prize or two if he buys enough tickets. No admissions price, no banquet, no expensive hotel room – just the cost of getting there with the family and tent or camper.

I once had the pleasure of writing to the ARRL to tell them of the CB jamboree in Southern California at Bakersfield. This is the largest one in California and last year brought in around 12,000+ people. It cost nothing to park the car and go take a look see, only to camp and buy raffle tickets. The CBers put on these free jamborees to bring in the crowds (and make money), but the ham conventions charge for the same privilege.

A case in point: At the recent ARRL Pacific Convention held at the Royal Coach Motor Inn at San Mateo, California, I telephoned to find out about just going over to see the exhibits. The fellow on the phone told me that I couldn't get in without either buying the banquet dinner or paying ten bucks to see the exhibits. "Outrageous!" I said. Why should I drive a hundred miles to pay and see the exhibits when I can look in a ham magazine and see the same thing? And how is a young person going to scrape up the money to pay for the privilege of trying to get interested in ham radio as a hobby? No wonder there are so many new CBers if this is ham radio's attitude towards new members.

This convention was held in one of the most expensive hotels in the bay area. It would only draw in people with the big money to pay for it, and how many of us are rich these days? I'm sure there are plenty of hams who either cannot afford the fancy convention or are not willing to part with 10 hard earned bucks just to look at radio displays. My letter to the ARRL convinced me that they are not interested in the family aspect of ham radio and neither are those who put on conventions. It is the family activity that has made CB so popular and with that idea in mind here are some suggestions to catch a new ham:

1. Don't charge admission to get into an event for those who just want to browse around. This discourages the people who aren't sure they are that interested and who would leave rather than spend the money. Charge only for the lectures and banquet if you have to make money, but give these people a chance to see what it's all about.

2. Get your ham club to advertise classes for Novices and Generals at places where CBs are sold with the selling point being "Tired of CB? Get into the exciting world of ham radio with its wide open and uncrowded spaces!" When they call to find out more information, invite them over to see your station. Sell them so hard that they will trade the CB gear for ham gear and not cameras.

3. Don't ever have a Novice class without a General class scheduled back-to-back. I attended a class with 7 disgusted fellow CBers who were eager to get into ham radio. After we all worked hard to get the Novice there was no one there to help them set up their stations and no hope of doing what these CBers had really set out to do – TALK. CBers are talkers and they want to get to the talking stage as fast as possible or find something better to do with their time. Get them through that grand canyon between Novice and General quickly so they don't become discouraged and quit too soon.

4. Get the whole family interested in your ham radio club. Have picnics, parties, dances, and get the young blood interested in social activities. It is the young men and women who will be the future hams if there is something to spark their interest. Friendship with other young people is a great start towards sharing the ham experience. Get your wife or lover involved in social parts of the meetings; wives love to get involved with other wives at social gatherings and yak while you're yakking with the men. Here's your chance to sell her on ham radio as something other than the hobby you waste all your time and money on. Save the dull activities for regular meetings and the fun things for the family get-togethers.

I'm certainly not advocating the complete overthrow of ham radio as we know it today. I'd just like to

see interest generated from within the clubs rather than having the FCC constantly tell us "Use it or lose it." There may be a future in their Communicator class license, but it could also lead us right into the mess that CB is in today. Then how do we stop it in our bands?

Wouldn't it be better to get your family and friends participating in your hobby and also become socially active rather than be hiding in the shack all the time? This is a great way to meet the fellow hams you have spoken to but never met. The CBers have done this for years with obvious success, and even the square dancers make a family event out of their hobby. It's time to get rid of the stuffy, antisocial attitude that most hams have about CBers and show them we are friendly types who are interested in bringing new members into our hobby. A typical CBer feels that hams talk like computers in 26 syllable words that scare them away before they can learn what those big words mean. And you'd be surprised the number of hams that I've met through CB because they crave the social family excitement that CB has to offer.

But most of all, don't lose the Novices before they become Generals. They have worked hard and you've wasted your time and turned them off completely if the Novice license expires and no one has come forward to show them how to get into the big leagues. New hams are out there for the asking; it's just a case of showing them that you are real people and are interested in them personally. With a little effort in the right direction those clicks you hear will be energetic new Novices rather than ex-CBers with their Japanese cameras. ■

A 450 MHz Transceiver for Under $130?

-- bringing 450 within everyone's reach

A UHF 450 MHz FM transceiver may be built for less than $130 by following the details given in this article. This basic transceiver is a single channel unit, developing better than 1 Watt of output, and has a receiver sensitivity of at least .3 uV. The unit is totally modular and may be expanded upon at a later date to include a 10 W amplifier, multi-channel operation and scanning capability. All components are readily available and the unit may be constructed by the average amateur in 16 hours or less.

The Basic Transceiver

In a previous article[1], a complete modular two meter transceiver was described using VHF Engineering kits. Because of the success of this approach and because of the large amount of interest and favorable comments received, we decided to use the same approach for a 450 MHz transceiver. Thus, this transceiver uses the transmitter and receiver kits manufactured by VHF Engineering of Binghamton, N.Y. These kits are a good choice since they are inexpensive, reliable, easy to build and perform well.

The Receiver

The receiver used for this transceiver is the VHF Engineering RX 432C. It consists of 4 basic modules: an audio module, a 455 kHz module, a 10.7 MHz module and a 450 MHz converter. The first three modules are the same modules as used in the 2 meter receiver. The converter module is different. The converter module will tune any 2 MHz range between 420 and 470 MHz without retuning and features a varicap controlled AFC circuit.

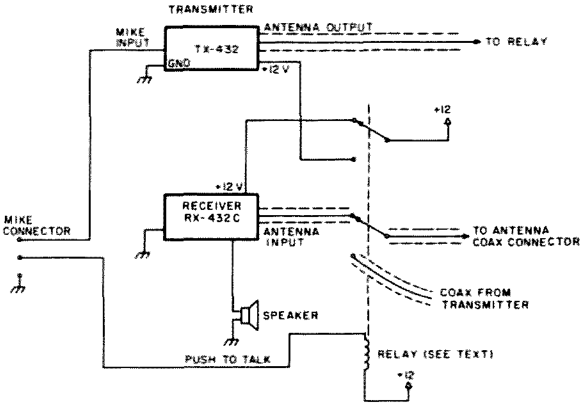

Fig. 1. Basic transceiver connections.

The AFC circuit is designed to control the receiver crystal oscillator and serves to keep it on frequency. It has a maximum control or pull in range of approximately 3 kHz.

Since the receiver, with the exception of the rf converter module, is the same as the VHF Engineering 2 meter receiver, owners of the 2 meter receiver need not purchase a complete 450 MHz receiver in order to receive 450. Only the 450 MHz converter need be purchased and substituted for the 2 meter rf converter board. If the builder wishes, he may use both converters and connect a switch to select one or the other front ends.

Receiver Multi-Channel Option

The basic 450 MHz transceiver as shown in the photographs did not include the multi-channel option since this option did not arrive in time to be incorporated into this article. The 450 MHz receiver multi-channel option differs from the 2 meter option in that a separate oscillator is provided on the multi-channel deck. This option may be incorporated into the basic unit or it may be added at a later date. The option adds 10 receiver channels to the transceiver.

Scanner Option

The latest version of the channel scanner from VHF Engineering scans 10 channels and incorporates a priority channel feature. The priority channel feature causes the scanner to periodically check a designated priority channel for activity when the scanner is locked on another channel. If activity is detected on the priority channel, the scanner will switch to the priority channel until the channel becomes quiet. It then will return to the channel that it was previously locked onto.

The Transmitter

The 450 MHz transmitter uses the same basic circuitry as the 2 meter and 220 MHz transmitters, but contains an additional doubler stage to drive the final directly at 450 MHz. It is rated at a nominal 1 Watt output; however, the units which we have built have given outputs in the 2 to 3 Watt range as measured on the Bird Wattmeter.

The basic transceiver did not incorporate an amplifier in order to keep the cost of the basic unit to a minimum and to keep the current drain down to a point where portable operation using battery power would be feasible. An amplifier may be added later if desired by using the VHF Engineering PA 432/10 10 Watt power amplifier.

Transmitter Multi-Channel Option

The transmitter multichannel option expands the basic transmitter to 10 channel transmit capability. It is the same option as used on the 144 and 220 MHz transmitters.

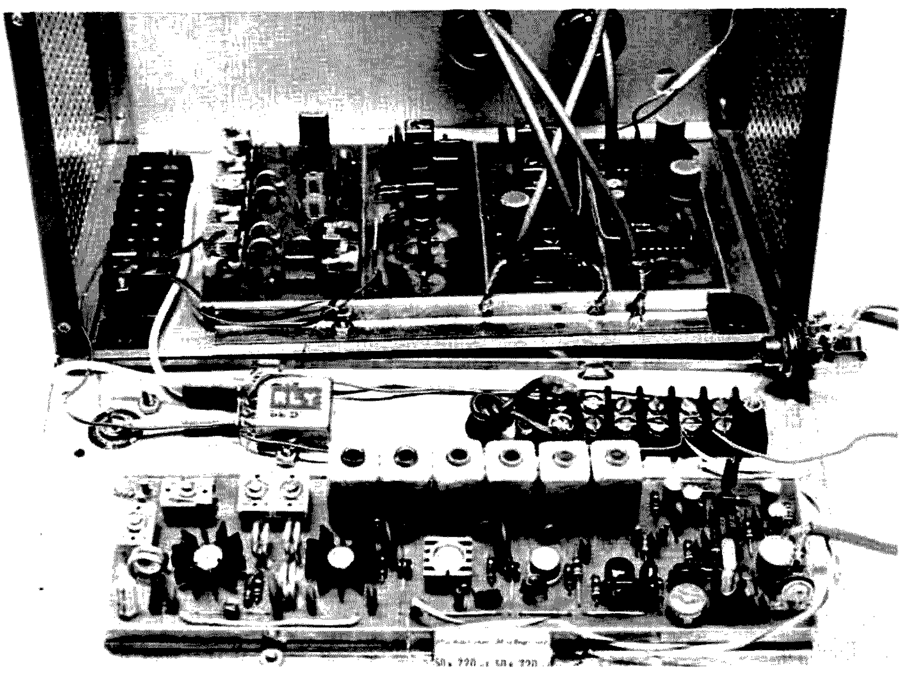
Construction

The 450 MHz transceiver as shown in the photographs was built into a standard Calectro cabinet and measures 9" x 5¼" x 4½". This cabinet was used because its size and construction would facilitate easy assembly of the transceiver without undue crowding. The receiver was mounted on the bottom panel of the cabinet and the transmitter was mounted on the rear panel as shown. The speaker was mounted on the top panel projecting upwards, but will be moved to a side panel location if an amplifier is eventually used. The top panel would then be used for the 10 Watt amplifier module.

VHF Engineering is now offering a cabinet specifically designed for this transceiver. The builder may wish to purchase the cabinet specifically designed for these units.

Hookup

The hookup for the 450 MHz transceiver is the same as for the 2 meter transceiver as shown in Fig. 1, except that the high pass filter used



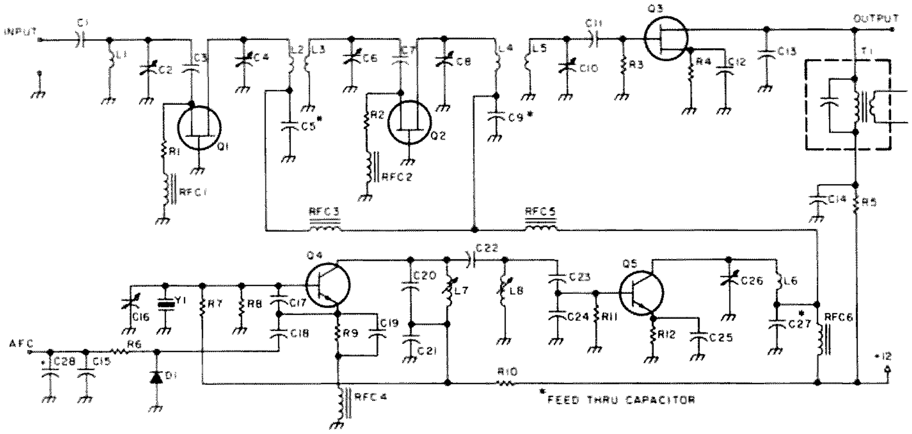


Fig. 2. 432 MHz converter portion of receiver.

in the microphone circuit for the 2 meter transmitter is not needed for the 450 MHz unit. This high pass filter is included on the 450 MHz transmitter board. (Note: All current VHF Engineering transmitters now have the high pass filter included on the PC boards.)

It is important to use a good quality transmit/receive relay to avoid excessive losses at the UHF frequencies. Further, it is important to use coaxial cable (52Ω) from the transmitter and receiver to the relay. VHF Engineering can furnish a T/R relay if you wish.

For a microphone, a medium impedance dynamic unit (also available from VHF Engineering) may be used.

Operation and Performance

The units that we have assembled for use into the WR1ABM 450 MHz repeater have been performing far beyond all expectations. Receiver sensitivity as measured in the lab has been better than .15 uV, while transmitter output power has been running from 2 to 3 Watts. Operation, from both mobile and base station environments, shows that the power output from the transmitter is sufficient to maintain a full quieting signal over most of the repeater coverage area. This transceiver has shown itself to be very rugged and it appears to be equal in performance to any solid state unit now on the market. ■

Space Age Junque II

--updating the 348 by 30 years

If I may make reference to the first paragraphs of Part I of this article (*73 Magazine*, March, 1976, p. 34), it should be easy for you to see why my 12 years of designing, adapting, and modifying around the basic BC-348 receiver package could not be covered in a single article, even if all the failures and quasi-successes were left out – and I assure you that they will be!

It is my purpose in Part II to add one more modification, AFC, that we have found very useful in copying both Oscar and EME signals. In addition, since alignment is required for this modification, and in general for a properly operating receiver, I'll throw in a few tips I have found very handy in securing top performance from any receiver – even if the AFC doesn't interest you. I have the sometimes envied position of having electronics as both my career and hobby, and because of this all of my ideas and modifications have been checked and evaluated both in amateur-equipped shops and in those using more sophisticated lab grade equipment.

My modifications are kept straight by my use of the letter M (modification) and a number (you did M-1, the power supply, and M-2, the audio module, from the March *73* article). Since all modifications are not in all of our receivers at any one time, and the M-# described the order in which I tried things, don't let any missing numbers in these articles bother you. The AFC part to be described in this article, for instance, is M-3A (M-3B was a transistor version).

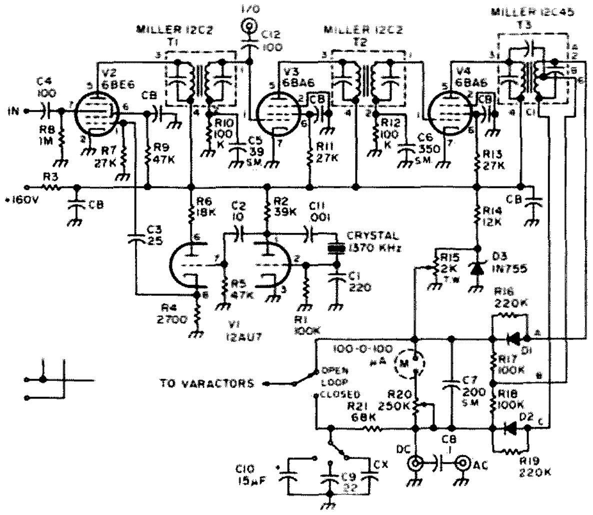

Fig. 1. Schematic.

The M-3A AFC unit is an adaptation from an article by W4EPL (*QST*, March, 1966) for the low i-f mixer scheme, and another by K7DEP (*73*, October, 1973) for the rf discriminator. Whether the overall unit is run "open loop," and only the tuning meter is used for manually tuning and correcting frequency, or you later use another of my modifications (M-4) to change the HFO portion of the BC-348 to a varactor oscillator to run full "closed loop" AFC, this modification makes itself well worthwhile.

When you get your receiver up to full AFC capability, you will wonder how you ever worked some modes without it (e.g., Oscar, EME, RTTY, SSTV, FAX, etc.). At least I don't remember Wayne ever having any articles on growing a third and fourth hand, and, with one on the elevation controls and one on azimuth, I find that both of mine are full – without having to tune a receiver drifting with Doppler, etc.

The AFC is a simple tube-type, with a circuit board layout to remove the pains of punching the chassis, wiring terminal boards, and so forth. The board is laid out so that you can run my 28 V dc filament scheme or use your 6.3 V ac filament line in a present receiver, if that is how you did your BC series rig. The components are all common parts, and within reason I left pad sizes large enough to allow for substitutions (i-f transformers, etc.). The mixer-oscillator alone is worth the time it takes to bring the odd 915 kHz i-f frequency of the BC-348 down to 455 kHz for other uses (panadapters, Q multipliers, etc.). The overall board size was chosen to fit over the dynamotor well where many BC-348 modifications placed the power supply. I have found the external power supply (along with its cable)

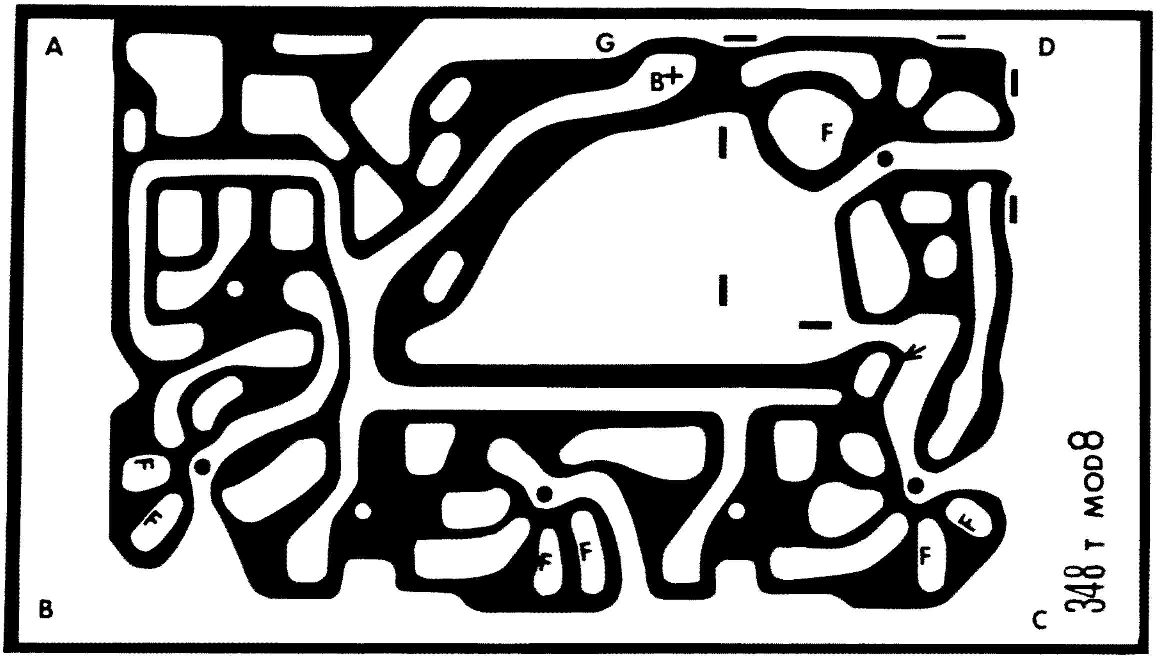

Fig. 2. PC Board (full size).

to be of no special disadvantage, since an external speaker was already called for (meaning at least a two piece rig anyway). If nothing else, a decent size speaker can be used in this layout, versus a pip-squeak tinny type if you tried building it in.

As with all circuit board projects, a minimum of part by part construction help will be written out. Follow the parts list, board layout, and schematic carefully, and you should encounter no problems. A tuned input circuit was intentionally omitted, so you can put a crystal into the unit that is 455 kHz *above* the i-f frequency you are going to feed in and get an AFC action the same as or comparable to mine.

I will make some brief notes on a few of the parts and their action, if for no other reason than to convince the wary that they *can* build projects, substitute parts reasonably, *and* get the projects to work.

Say your junk (sorry – junque) box contains a crystal on 1375 instead of 1370 kHz as called out – fine, the transformers T1 to T3 do have *some* tuning range – try it! R15 is a TW (thumbwheel), small, printed circuit pot of 2k. I made a nice spot for it on the board. If you have a place in the BC-348 (and there are lots of them) to put a full size pot or slider resistor of 2 to 4k for R15 – and you have one – use it! The same goes for R20. A bit harder to adjust a slider? Sure, but time – not money – should control what you try to do in your hobby, shouldn't it? Often you are scared off by a project because you don't have the exact parts, and on this one you shouldn't be. That is one reason (of many) I chose the BC-348 as a starting point. You need not have dreams of dollars with wings (your trade-in value) or crying spells every time I tell you to take drill in hand. The switch for AFC time constants (C9, C10, Cx), and the switch for the loop (open, closed), should be put on the BC-348 front panel, obviously, but the other things coming to the outside world can go where *you* want them. The meter can go in the panel, a box, with the speaker and power supply in that panel, etc. My S-meter (another modification), speaker, power supply, AFC meter, etc., are all in a box separate from the receiver and are at the operating position (my receivers are rack-mounted and remote-tuned).

The parts list describes the parts I used and should be pretty well self-explanatory. One incidental I should mention, however, is that the dc output jack can be used with a pen recorder – or to drive a VCO like the 566 IC, to produce a tone that can go onto any inexpensive tape recorder. I have used the tone to track Doppler shifts on many of the satellites. It (the dc) can also be used as a point that gives demodulated FSK signals (RTTY fans?). Also, the ac output just happens to be the FM (desired or undesired) of the incoming carrier (FM anyone?). The capacitors shown unmarked in T1, T2, and T3 come in the transformers that are specified, the CB are bypasses as called out in the parts list, and R3 is not needed if the unit is run off the +160 V dc (replace it with a jumper wire). The B+ at the connection to the board should be +160 V dc regardless.

If your present i-f is already 455 kHz, or you want a 455 kHz take-off point for other projects, include C12 and the jack. If you have 455 kHz, all of V1 and V2 and components can be deleted; feed 455 kHz into the AFC unit through the jack. If you don't, include C12 and the jack, and use it in the future as a 455 kHz take-off point.

It's built – now what?

Now, as promised, the rundown on noise, alignment, etc., for all receivers. Most of it we have learned the hard way, having either evaluated it with lab grade equipment and then duplicated it using somewhat more crude instruments, or vice versa. Either way, the ideas work and have been proven out *both* ways, so you can have some faith in the premise that they are worth your time and trouble.

First, the AFC unit, since it is the simplest and its initial alignment can even be done while it's completely out of the receiver. Hook +160 V dc

to the +160 point (B+) of the circuit board, and the +28 V dc or 6.3 V ac to the filament point, depending on how you put the jumpers into the board. M, the meter, should be a zero center type; a 100-0-100 uA was used. If new transformers are used, feed in the same frequency unmodulated carrier as that of the i-f you intend to connect to (BC-348, 915 kHz), and place the proper crystal into the socket (BC-348, 1370 kHz). A VTVM set for minus (-) dc at VI pin 2 will tell you if V1 is oscillating as the grid bias varies when you place the crystal into the socket. With the new LFO running and a moderate signal fed in, align T1 and T2 for maximum negative voltage at pin 1 of V3 and V4, respectively. Remove generator input. Set R15 for about 6 V dc at the open loop terminal of the loop switch (may have to be varied later with varactors chosen). Set R2 for a zero reading on the meter for now. Connect the signal generator again and, using the rf probe on a VTVM or scope, tune the primary *only* of T3 for a maximum of 455 kHz across the secondary of T3 (A to C). Do not attempt to zero the secondary of T3 at this time. That's it for the AFC unit for now.

The basic receiver alignment and noise:

The receiver referred to here is our BC-348 series, but the ideas and methods used work equally well with any receiver. First, alignment. To do a good job of alignment using ham grade test equipment, let the generator stay on a *minimum* of 24 hours, and the receiver at *least* one hour. Our receiver runs a whole day, and the generator, a not too shaggy military item, is *always* running!) Pick the tuning range of interest. I used the 15 to 15.7 MHz region for my 2 meter convertors, such that 145 MHz equalled 15 MHz, 145.1 MHz equalled 15.1 MHz, and so forth. If you want a top-notch tunable i-f for convertors, give up the idea of using the same receiver as a general coverage instrument. We aren't going to "kill" the rest of the receiver – just put its best kind of performance where it counts.

Use 15 MHz WWV to very accurately set your oscillator trimmer, and allow one minute after each adjustment to be sure it stays put! Compression trimmers sometimes "relax" after your mechanical pressure, as well as torque, leaves them. If you have a counter, put its probe "near" the grid of the mixer and not down the oscillator's "throat," as that would pull the oscillator off frequency from where it will be when you remove the counter. If you are going to use the crystal filter or some other i-f filter, have it in and running at this point. Monitor the AGC line in the receiver – don't use your ears to judge alignment or improvement! More negative AGC is more signal. Keep the generator low enough in output to let the meter vary with i-f transformer adjustments. You want the 915 kHz i-f lined up on the crystal filter or filter you are using, so rock the generator around slightly and look for improvement – output. You won't get such a gain drop when the filter is switched in this way, and those old crystals do age in (one of mine is at 913.8 kHz). Align slowly and carefully, getting every tenth of a volt more negative AGC that you can. Work from the audio end toward the rf in

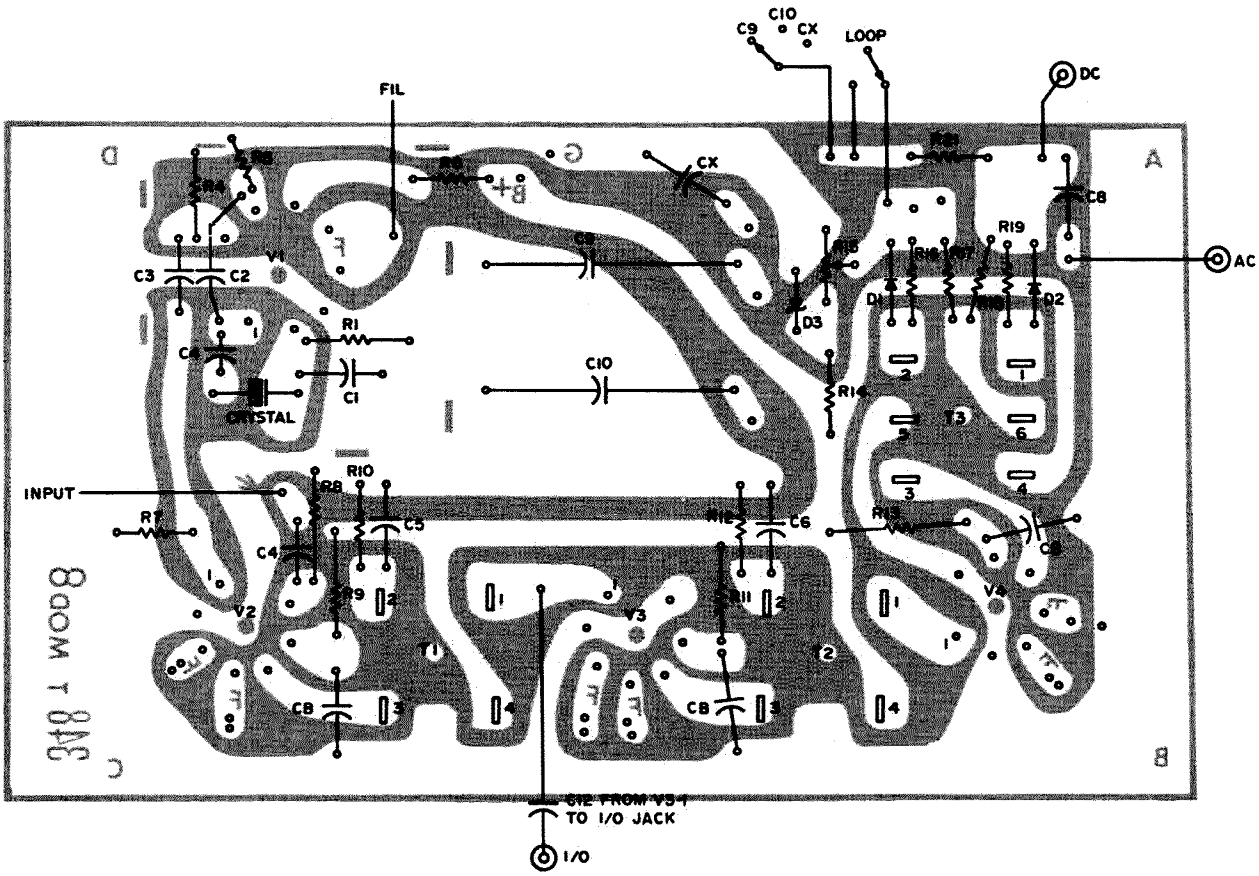

Fig. 3. Component layout. Some resistors are mounted standing up (e.g., R5). R2 is on copper side (B+ to pin 1 of V1).

and do it several times, as each time may gain a bit more. Remember, a volt of AGC increase is a lot of signal gain carried to the detector.

On my BC-348, a good AGC reading to maintain seems to be about -3 V dc on a 0-10 V scale. Adjust a slug or trimmer to get maximum negative AGC, then reduce the generator to return to the -3 V dc reading, then do another slug or trimmer, then return to -3 V dc, etc. This seems to maintain a good rf level at the detector, without saturating or "cramming" it. The result is a meter that gives good smooth changes that are easy to see and follow as you are adjusting. Follow this procedure throughout the low i-f (915 kHz), and then tune the generator and receiver to the upper limit of interest (15.7 MHz).

At this point, align the trimmer capacitors on the rf tank circuits. You will wreck the 13 to 18 MHz tracking and gain ability doing so, but the 15 to 15.7 MHz region will be set up at its best, as we wanted. Also, the rest of the bands remain unchanged (for those who care). You are setting up the maximum gain L-C condition for your tunable i-f, and not trying for a general wideband receiver.

With the alignment done, change the front panel rf connector to a BNC or UHF type to mate your convertor cable. Remove the 100k or 470k resistor from the center of the old antenna input to ground, and discard it. You are no longer going to have this point tied directly to an antenna, much less to a static noisy aircraft antenna, and the resistors change value – sometimes going down to 1k. Replace the wire from that connector to the first rf can, and replace it with a short piece of coax (RG-174 is fine), with the ground tied at the panel end only. While in this region of the receiver, short the wires on the pot mounted to the end of the main tuning capacitors (this pot helped keep gain variations down from band end to band end – by reducing gain!). Another improvement, if only small, will be noticed.

As for the noise cures, several noted here apply to all receivers. Mass produced goods just can't get handbuilt care – another reason for rolling your own – even if you start with the hard mechanical part already done.

The 991 gas voltage regulator used to regulate the B+ to the oscillator is the best little rf "hash" generator you can find, and there it sits, right next to the rf and 1st mixer grids. (Nobody said the BC-348 was perfect as purchased!) The 991 or a suitable zener diode replacement must be moved to your power supply, but be sure to remove the 991 at all costs. Clip one of its supply resistors so you don't ever accidentally replace it. Use another wire of the power supply cable to bring this oscillator B+ up to the receiver. A .1 mF capacitor to ground should be added to the point where this B+ line enters the oscillator can, where it enters the receiver, and where it leaves the power supply. Now the oscillator should be running on dc at least, and the ton of hash stays "canned" at the power supply.

The improvement to the whole receiver (other bands, too) in the noise and racket department should be dramatic (and include the lack of hum, if you used the +28 V dc on the filaments as suggested). While on the subject of the +28 V dc, you can now try our most noticeable improvement for the amount of effort! Tune in a fairly weak but steady station, preferably voice (so you don't need to concentrate on CW). Put your dc voltmeter on the +28 V dc line and begin to reduce the +28 V dc by turning the pot down on the regulator board. The gain available in the audio module will go down, as well as the thermionic emission from each tube. The oscillator *may* move frequency slightly, and the overall noise goes down. Correct any frequency shift, and turn up the volume control only. Hear the difference?

An SASE has become mandatory since Uncle Sam went to his unlucky "13," but I *will* try to help anyone with problems. ■

Parts List

Printed circuit board (per 1:1 template)
Assorted jacks to suit builder (outputs/inputs)
V1 – 12AU7 – osc.-buffer
V2 – 6BE6 - mixer
V3 – 6BA6 – low i-f
V4 – 6BA6 – low i-f
T1-T2 – Miller 12C2
T3 – Miller 12C45
D1-D2 – 1N914
D3 – 1N755 – zener
R1 – 100k ½ W
R2 – 39k ½ W
R3 - as req.
R4 – 2700 ½ W
R5 – 47k ½ W
R6 – 18k ½ W
R7 – 27k ½ W
R8 – 1 meg ½ W
R9 – 47k ½ W
R10 – 100k ½ W
R11 – 27k ½ W
R12 – 100k ½ W
R13 – 27k ½ W
R14 – 12k ½ W
R15 – 2k lin. pot
R16 – 220k ½ W
R17 – 100k ½ W
R18 – 100k ½ W
R19 – 220k ½ W
R20 – 250k lin. pot
R21 – 68k ½ W
C1 – 220 pF s.m.
C2 – 10 pF disc
C3 – 25 pF disc
C4 – 100 pF disc
C5 – 39 pF s.m.
C6 – 350 pF s.m.
C7 – 200 pF s.m.
C8 – 0.1 uF mylar or paper, 100 V
C9 – .22 uF mylar or paper, 100 V
C10 – 15 uF elect., 25 to 50 V
C11 – .001 uF disc
CB – .1 to .33 uF mylar or paper, 200 V
C12 – 100 pF disc
Assorted switches to suit location and builder
Loop (open/closed) – DPDT – second half to lamp indicator
Loop (capacitor) – SP3T – slide or rotary
Meter – 100-0-100 uA – size and shape to fit builder req.

by Wayne Green W2NSD/1

I/O EDITORIAL

uP IN OSCAR

The next Oscar is being designed and built in Germany with help from Canada, and they're putting in a microprocessor . . . RCA COSMAC CDP1801 . . . to help sort out the input stations running more power than they should . . . one of the more serious problems which have been bothering Oscar 7 on the 432 MHz uplink.

The uP will also control the attitude of the satellite with magnetic torquing, spin rate and boost motor control, transponder times on and off, format of the telemetry beacons plus analog to digital conversion of signals and commands.

By the time Oscar 8 is up there, a good many ground stations should be running with uP control and probably a number of automatic contacts between uP operated stations. Even a simple microprocessor will let you know exactly when Oscar is accessible . . . and exactly where . . . even what Doppler shift to expect. It will control your antennas and keep them aimed exactly at the satellite. Hmmm . . . one hundred countries worked in one hundred seconds? Maybe we should offer a certificate.

OPPORTUNITIES

Hardly a day goes by when I don't get a phone call from someone wanting me to answer some questions in the microprocessor field. As more and more businessmen become aware of the possibilities of these computer systems, anyone with a good knowledge of them will be able to do very well.

I get calls from microcomputer manufacturers asking if I know people who might be able to work for them in developing their equipment and software. Other manufacturers are looking for people with enough uP background to open computer stores and sell their systems. And about once a day I get a call from a businessman who would like to have a uP system put together and programmed for a particular application . . . can I suggest what equipment would be best and how he would get the programs? Other manufacturers are desperately looking for people who can write and help them put together ads, instruction books, articles and brochures.

My answer to them is the obvious one: get in touch with some of the authors of articles which appear in *73*. About the *only* way to establish a reputation in a brand new field is by writing articles and books . . . publish and prosper. It's nice not only to be paid for the article, but also to have manufacturers and businesses fall all over you with job offers and consulting assignments.

Okay, you'd like to make some money writing . . . and it wouldn't look bad on your resume . . . or perhaps you'd like to get out there and really get going in the uP field and be in the line for the big money that is going to be here . . . and that means you want to build your reputation . . . so you wonder what to write about.

Once you get started writing you'll find it impossible to stop. There is so much to cover that it is endless. If you've gotten an Altair up and working you've managed to solve a dozen or a hundred problems. Hopefully you've kept a day-to-day diary of your progress (or lack of it). This didn't work at first and you found the problem . . . a whole lot of other people are desperate to know how you got that solved. Like all the time I wasted with my Altair trying to get it to interface with the Southwest Tech TVT-II . . . what a hassle! It turned out that the TVT was sending out lower case letters to the Altair, but was printing upper case on its screen. Once someone suggested using the shift key on letters, there was no further problem. Little problem, big deal.

Sphere system users have had their share of miseries and there are a lot of us who would like to learn from them. Ditto Imsai and all the other systems. Like how many of you have been able to get a teletype working right off with your system? Or a cassette recorder? We still don't have the ability to put a program on a tape without dumping everything, but we'll get it solved one of these days.

Maybe you've tried the Ohio Scientific learning system . . . what was your experience? How about terminals . . . all of us need some perspective on the various terminals available . . . HAL, SWTPC, Interactive Systems, etc. How about using some surplus terminals such as the Sanders, Burroughs?

Software . . . readers are gradually getting used to the idea that they are going to have to program their systems, but they don't know much as yet about where they will get the programs or how to learn to use them. Where can the reader get all of the free programs that are available? What books are best to learn to use FORTRAN . . . BASIC . . . etc?

BEST uP YET?

We've had several letters from readers all excited about the Levy microprocessor in the June issue (page 106), saying that this is by far the best microcomputer design yet and the *first* how-to-build-it uP article in *any* ham magazine. A letter from Pete Stark K2OAW, who is an expert in this field since he teaches it in college and has several books out on computers and programming, was particularly welcome.

FACTORY RECALLS

A call came from Bill Godbout with a request that all purchasers of his Econoram kits (before June 15th) drop a card to Godbout with the invoice number of their order. It appears that the kit was too good, in a way. It works a bit too fast for some of the systems and Bill has a retrofit kit which will fix up any problems purchasers may have been having or might eventually have. How about *that* for an advertiser?

WORD PROCESSING

You'll be seeing a lot of the term "word processing," so it will help if you understand just what this means. Good luck . . . for in the computer field it has a wide range of meanings and when you bring up word processing (can we shorten that to WP for now?) you still have to make sure that you and your friend are talking about similar things.

One person will think of WP in the context of setting type for a book or magazine. It is being used for this, and such uses will be growing rapidly. In this case you set your words on a video terminal and then, when you are satisfied, you can put them on tape to be set by a photo typesetting unit.

The use of a video terminal allows a lot of flexibility. With a good WP program and some "intelligence" to use the program, you can move characters, words, sentences or even paragraphs around as you please. Once you are done, you can have the finished work printed or put on some memory medium for later printing. This is one very good application for low cost microprocessors.

Your WP program can be made to justify lines or to have them fit around illustrations, as in magazine pages. Some magazines and newspapers are using such systems to set and arrange whole pages at a time. These systems are not inexpensive . . . yet.

Perhaps you can see why a secretary or a businessman would go for a WP system . . . the savings in typing letters can be enormous. One error on a letter . . . or a change in a shipping date . . . does not force the whole letter to be retyped. Sentences or even paragraphs can be held in memory and put in letters easily. It is the invention that could do away with the typewriter.

Suppose you want to send essentially the same letter to fifty firms (or congressmen). A typist had to type out the fifty letters before . . . now the WP system will turn them out quickly with but one typing. You can even have the mailing list in memory and tell the processor to send one letter to each on the list. A system along this line is used to generate those letters which appear to be typed directly to you . . . *Reader's Digest* is big on this idea. Blanks are left in the letter form to be filled in by the processor with your name and address.

How much stock would you buy in a typewriter company when you can see word processing on the way? We're looking at possible video terminal prices on the order of $500 (eventually half that) and line printer ones of $1000, which can handle dozens of terminals for all but large scale production of form letters.

CREDIT DUE

Several readers have asked about the Biorhythm computer program I mentioned as being available in my review of the MITS Altair Convention. I got my copy from In-Touch Systems of El Paso and my thanks to Richard Bandat for his consideration. I also got three business programs, but haven't been able to use them as yet. The *73* uP lab is just now being finished . . . once it is in shape we'll have a lot of equipment up and running and be able to start testing out programs for possible distribution.

Recent equipment received for the lab includes two Imsai computers, a MITS disc system, a Burroughs video terminal, and a Wavemate Jupiter II computer. The Jupiter is on test by John Craig.

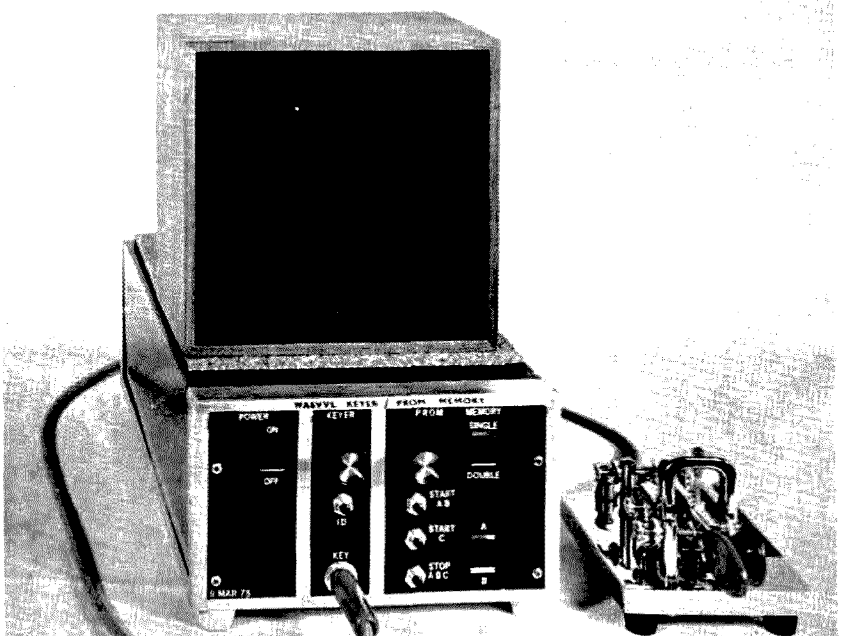
PROM Memory Revisited

-- getting back to May's CW blockbuster

The thought of using a CW memory did not occur to me until Greg Kordes WA6EEB demonstrated his keyer/memory at the local radio club (Newport Amateur Radio Society, NARS). Greg's keyer/memory utilized a 512-bit random access memory (RAM) which was easy to operate and program, and generated considerable interest.

Here was a piece of equipment which would complement my keyer, be fun to operate, and store those often repeated parts of the QSO.

During the following weeks, I sent for some specification sheets and resurrected old ham magazines looking for related articles. When I first started, I had no idea what exactly I wanted or where I was going. All I knew is that I wanted a keyer with a CW memory and that I had several articles I could use for reference.



Photos by Alan Burgstahler WA6AWD

My first attempt at building a keyer/memory was a 2560-bit keyer/RAM memory which utilized ten 256-bit RAMs. Memory retrieval was either automatic, using a decade counter and decoder to select the appropriate chip, or manual, using a ten position thumbwheel switch. An LED readout let me see which RAM was being programmed or read. My first attempt was about 90% completed and operating before I found that I was programming the same information into the RAM memory every time I turned on the power.

At this point, I determined that *my* CW operating habits did not require the versatility of the RAM and that my memory requirements could be satisfied with one or more programmable read only memories (PROMs). Although the control logic for the read modes are similar for RAMs and PROMs, PROMs offer a non-destructible memory (within their recommended operating parameters) after their initial programming, without the need to frequently refresh the memory as is necessary with RAMs.

My next CW memory was a self-contained 1024-bit PROM memory utilizing four 256-bit Intersil PROMs[1]. This was so successful that I decided to integrate the PROM memory with the WB4VVF accu-keyer[2].

The memory was increased an additional 1280 bits for an effective memory capacity

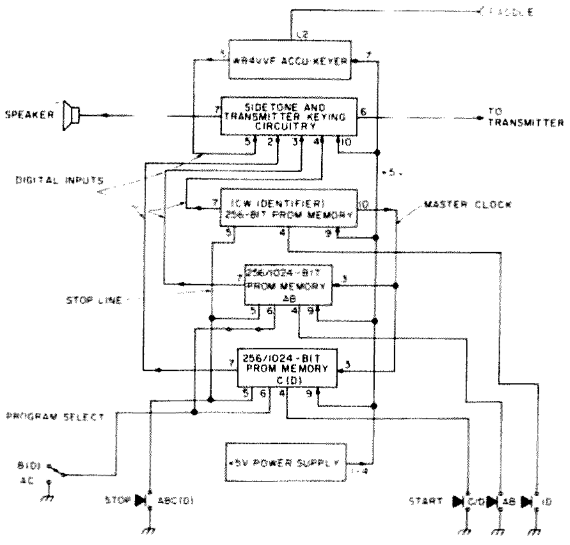


Fig. 1. Block diagram, keyer/memory.

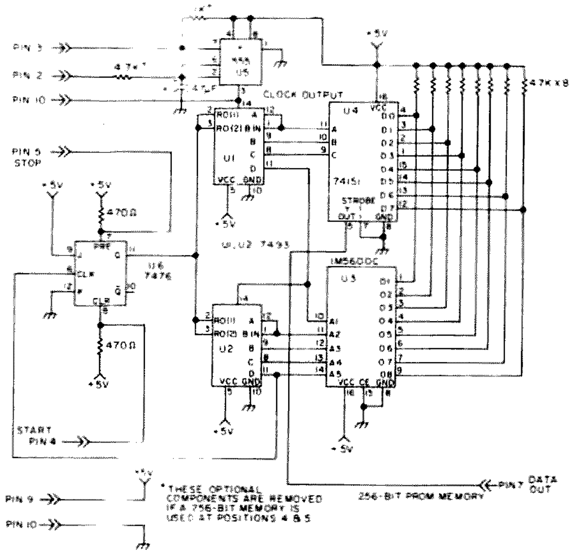

Fig. 2. 256-bit PROM memory.

of 2304 bits (2304 bits = 2 x 1024 bits + 256 bits). Memory expansion is simplified by adding additional memories as the reader's memory requirements, space and pocketbook allow.

The keyer/memory described is completely self-contained and is designed to drive grid-block keyed transmitters with key-up voltages not exceeding -100 volts.

Fig. 1 shows a simplified block diagram of the keyer/memory.

Memory

The PROM memory section (boards 4-6) contains one to three memory boards using two Intersil PROMs, an IM5600C (256-bit, 32 words by 8 bits) and/or an IM5603A (1024-bit, 256 words by 4 bits) as memory elements.

A 256-bit memory, used as a CW identifier, contains a "master clock" for the memories. Both memory boards are laid out for a clock, but the components are not installed on boards 4 and 5. The schematic of the 256-bit memory, Fig. 2, shows the similarities in logic between this and my May article. 256-bit PROMs programmed for the previous memories can be used.

The 1024-bit memory contains approximately 90 characters of memory. The control logic for the 1024-bit PROM is such that two 512-bit programs can be selected by a front panel SPST program select switch (A/B). Removing W5 on the mother board (Fig. 6) and W3 on the 1024-bit memory, and adding W2 and W4 on the 1024-bit memory will enable the entire 1024-bit program instead of two 512-bit programs. Looking at the schematic of the 1024-bit memory in Fig. 3, notice that the method of addressing the PROM (U3) and U4 is slightly different than that of the 256-bit memory, necessitating a change in the programming format for the PROM. The larger PROM requires eight programming cards.

Except for a clock, the memory boards are completely self-contained with start/stop circuitry, address counters, parallel to serial conversion and PROM.

Memory retrieval for all memories is initiated with the appropriate program select push-button switch. The program(s) can be stopped at any point with the stop push-button switch.

Sidetone/Transmitter Keying Circuitry

The keying circuitry in Fig. 4 is essentially the same as that of my May article, with the addition of U2, an NE555 timer IC which is used as a sidetone oscillator,[3] and its control transistor Q2. A small speaker may be mounted on the board or the chassis, or connected through the external speaker jack (as illustrated).

Unused digital inputs (pins 2-5) must be grounded to prevent the transmitter from being keyed. Since no provisions have been made on the board or mother board for grounding the unused inputs, the output pin(s) of U1 (3, 6, 8 and 11) corresponding to the unused input(s) are not inserted into the socket.

Keyer

This position is "up for grabs." The reader may use his favorite keyer circuit or the accu-keyer which is adequately covered in the 1974 ARRL *Handbook.*[4]

My adaptation of the accu-keyer is virtually identical to the original with the exception of the board and removal of the power supply components (C3, C6, CR2, R13 and VR1 in the ARRL *Handbook*).

The speed controls for the keyer clock and memory clock can be ganged or mounted separately. I chose to use an SPDT switch and use both techniques (single/double). If your keyer utilizes a nonsynchronous clock, the memory master clock may be used for your keyer also.

Power Supply

The 5 volt supply illustrated in Fig. 5 satisfies the power supply requirements of the keyer/memory, supplying 600-900 mA with all boards in place.

As can be seen in the photograph, I used a 6.3 V filament transformer for the 5 volt supply. These transformers, when used with 5 volt three-terminal regulators, do not provide enough unregulated voltage at the input of the regulator to work satisfactorily at nominal line at high supply currents. There also seem to be large variations between similar transformers. The previous PROM memory was marginal at low line while the keyer/memory did not begin to regulate until 125 V ac line voltage. No problems with the keyer/memory have been experienced operating at 95 V ac with this transformer. For this reason and to keep U1's dissipation low, I did not replace the transformer. However, good design dictates a transformer with a secondary voltage of 7.5-8.0 Vrms and I would recommend using it.

Construction

The keyer/memory is housed in a BUD 12" x 7" x 4" aluminum minibox. The majority of the components are mounted on six single-sided 5½" x 3" glass-epoxy circuit boards. The boards are fabricated to fit standard 10-pin card edge connectors with .156" spacing. The boards, in turn, plug into a 6" x 3½" single-sided glass-epoxy mother board mounted against the front panel with mating 10-pin card edge connectors.

Using this modular approach, I have changed individual circuit boards and revised the mother board without affecting the front panel wiring. Also, the boards may be quickly removed for repair or inspection in just a few seconds.

The boards, in order of their appearance, are as follows:

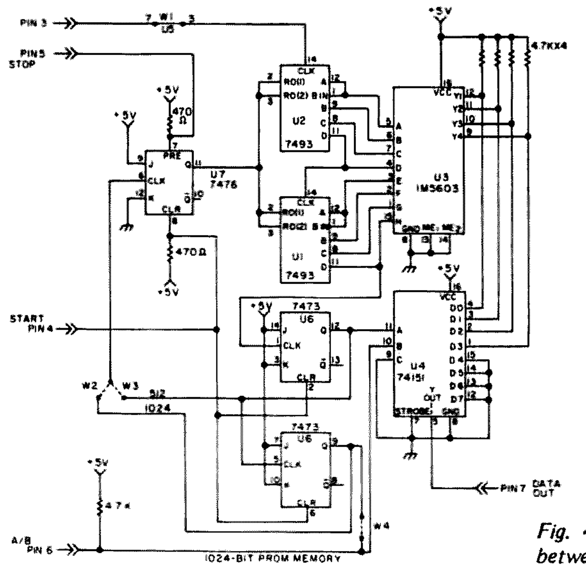
1. WB4VVF accu-keyer.
2. +5 volt logic power supply.
3. Sidetone/transmitter keying circuitry.
4. 256/1024-bit PROM memory.
5. 256/1024-bit PROM memory.
6. 256-bit PROM memory/CW identifier (includes the master clock for boards 4, 5 and 6).

The power transformer, fuse holders, ac connector, panel switches and controls are mounted on the aluminum minibox.

There are 27 integrated circuits and approximately 68 discrete components.

Again, sockets are advisable due to the cost of the integrated circuits and PROMs. They not only speed troubleshooting when

Fig. 3. 1024-bit PROM memory.



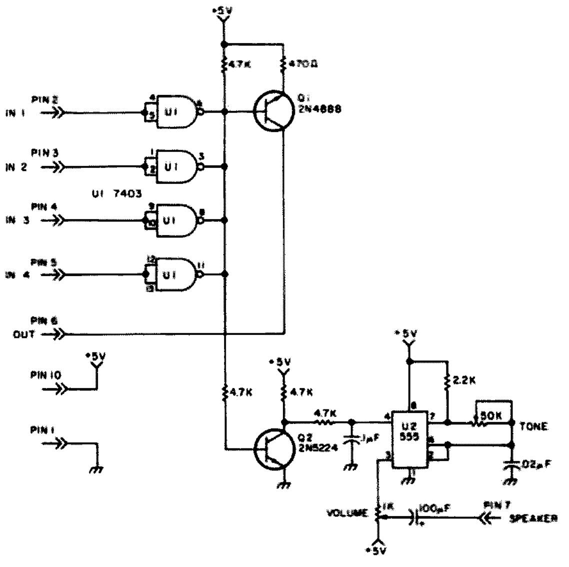


Fig. 4. Sidetone/transmitter keying circuitry. Note: Speaker is connected between +5 V and speaker out.

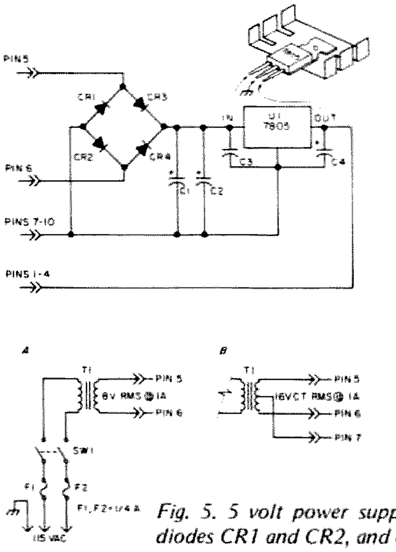

Fig. 5. 5 volt power supply. If a center-tapped transformer is used, remove diodes CR1 and CR2, and connect accordingly.

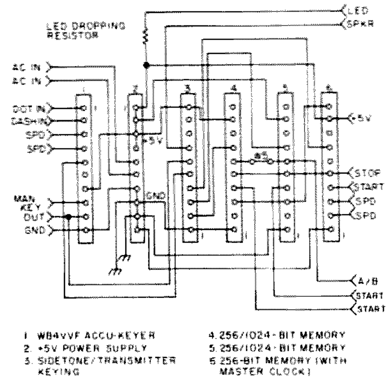

Fig. 6. Mother board.

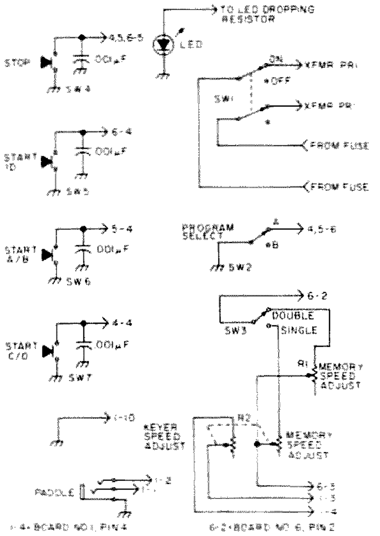

Fig. 7. Front panel wiring.

the need arises but also avoid overheating during the soldering operation.

After assembly, check the power supply voltage *before* plugging in the remaining boards.

If all parts were purchased new (based on the Cramer, Newark, and/or Allied industrial electronics catalogs) and you built your own printed circuit boards averaging $6 apiece, the total cost would approach $225. My total investment, purchasing most of the parts at electronic discount/surplus stores in the Costa Mesa area, was $100. It could have been lower but I made some mistakes along the way and changed design in midstream more than once.

Printed Circuit Boards

The artworks for all boards were prepared at home using commercially available artwork aids. They were taped 2:1 and photographically reduced at a local photo shop. The artworks were small enough to reduce two on one positive, cutting costs a bit.

Using direct positive photoresist-coated boards available from the Vector Electronic Co. (CU70/45WE-1R, 7" x 4½" 1/16" single-sided glass-epoxy), the boards were exposed in my darkroom (bathroom) using a positive. Following the instructions that came with the boards, I was able to make some very outstanding circuit boards.

After cutting and drilling, I tin-plate the finished board with Shipley LT-25 chemical plating solution[5].

I usually get better results etching with ferric chloride than with ammonium persulphate.

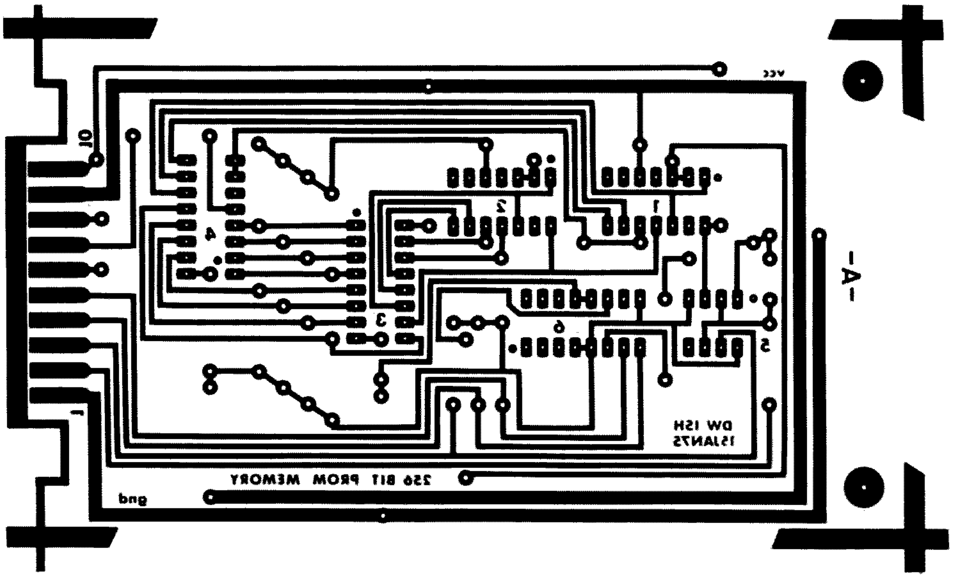
With careful planning and the above materials, I can produce a production quality board for approximately $6, which includes the photographic reduction of my artworks.

Programming

All of my PROM memories have utilized Intersil bipolar PROMs whose programming procedure forces a resistive shaft through the junction of one diode in the memory cell, resulting in a logic 1 at selected locations in the memory as determined from the user's program. Once the memory cell has been programmed to a logic 1, that bit cannot be altered (reprogrammed).

Although design data sheets and application notes are available from the manufacturer and distributors which describe the programming procedures (electrical) in detail, the reader will probably take advantage of the custom programming services offered through the manufacturer or distributor. Programming methods vary from

Fig. 8(a). PC board, 256-bit PROM memory (full size).



Note: PC boards are top views, or as viewed from the component side. Component layouts are bottom views, or as viewed from the circuit side.

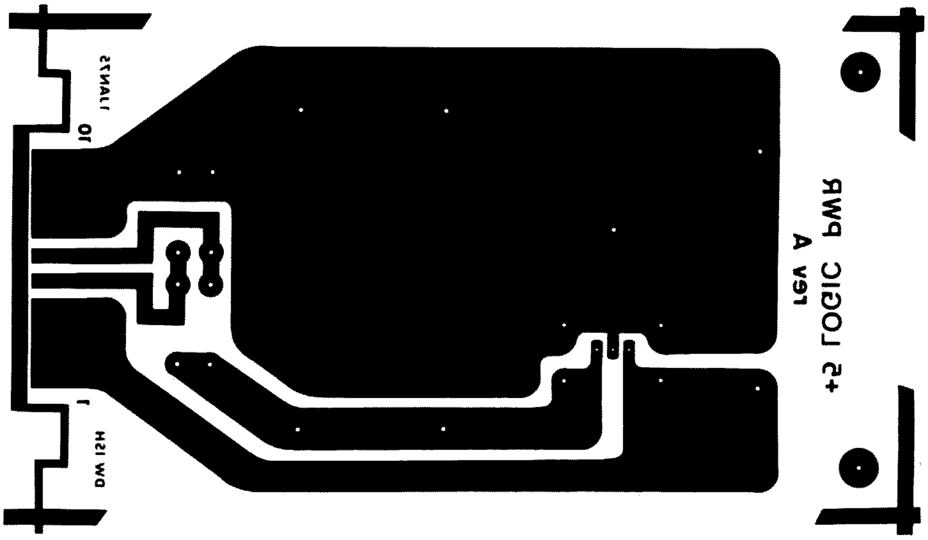


Fig. 10(a). PC board, +5 volt power supply (full size).

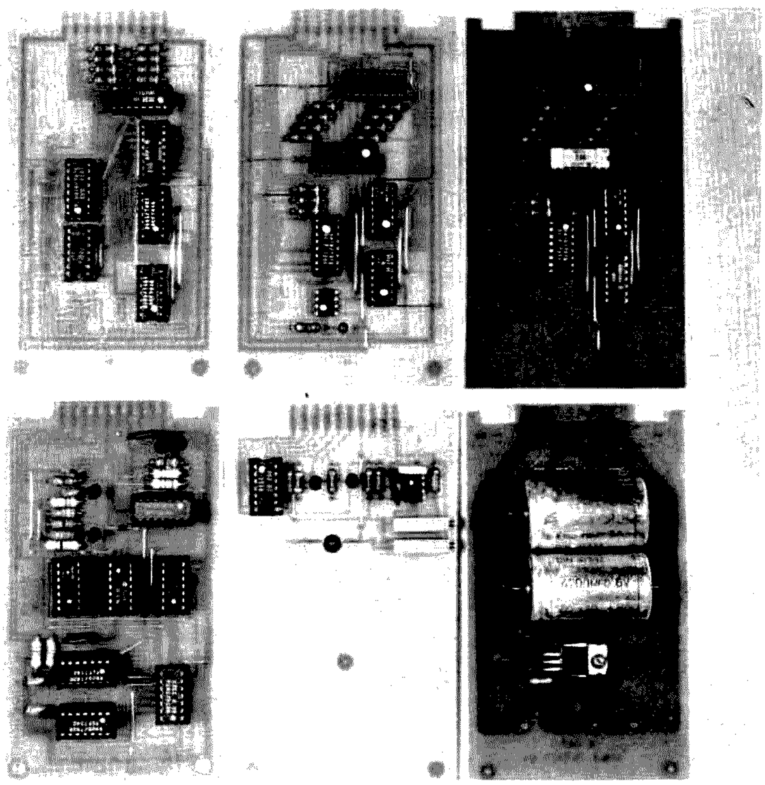
manufacturer to manufacturer and from type to type so that the reader will have to do some homework and some independent research in selecting PROMs. Send for the design data sheets and application notes corresponding to the PROMs selected. READ THESE PROGRAMMING INSTRUCTIONS CAREFULLY AND FULLY UNDERSTAND THE ADDRESS METHODS AS PROGRAMMING ERRORS CAN BE COSTLY. The quoted prices from R. V. Weatherford included programming costs and they supplied the programming cards and instructions.



Circuit boards. Clockwise, from upper left: 1024-bit PROM memory, 256-bit PROM memory w/clock, 256-bit PROM memory w/o clock, +5 V power supply, sidetone/transmitter, Accu-keyer.

Standard spacing should be used in writing your program: 7 bits for a word space, 3 bits for a letter space, 3 bits for a dash, and 1 bit for a dot.

Conclusion

The size of the memory and the PROM(s) used depend entirely upon how complicated your memory access is, your pocketbook, and your CW operating habits. PROM memories, because of their nature, are not versatile. For the CW operator requiring a versatile memory, PROMs are not the way to go unless a large memory is used which can be easily accessed. The more complicated your access scheme, the more complicated the memory manipulations during a QSO. Memory access in my case is through push-button switches, making it fast and fairly foolproof.

There have been about a dozen "good" articles on keyers with memories which have appeared during the last three to four years, and yet none of them has really satisfied my memory requirements. They were, however, invaluable as food for thought. The keyer/memory described in this article is the result of reading and partially building many of these articles which have appeared in *73*, *Ham Radio* and *QST*.

My primary purpose in writing this article was to demonstrate another method of building a CW memory so that, if one was interested, he could use this and other articles to build his own, tailored to his operating habits. The keyer/memory described has been designed specifically for my CW operating habits and is not meant to be a "better mousetrap."

There is little difference when switching from "fist" to memory other than character and letter spacing. No one has noticed a difference to date, or commented on it if he has.

No RFI problems have been encountered

to date keying a Kenwood TS-511S to 350 Watts (input). Additional bypassing may be required at higher inputs.

Whether the reader chooses RAMs or PROMs for his CW memory, anything which can be sent with a key can be put into memory. Try it, you'll like it. ■

What's When

--timing diagrams

A timing diagram is one of several "road maps" for digital circuits. Aside from providing us with a "picture" of what a waveform should look like at the output of a circuit, it can also tell us the exact conditions which exist within a circuit for any particular instant in time. The latter can be very helpful information when troubleshooting a circuit. Being able to generate a timing diagram to the point of determining what the output waveform looks like is a useful tool in analyzing and learning digital circuits.

We're going to be discussing timing diagrams from two different angles. First, we're going to take a look at some of the fundamentals and techniques involved in *generating* a timing diagram. Secondly, we're going to examine a couple of manufacturers' diagrams and discuss the *interpretation* of same.

A Basic Timing Diagram

Fig. 1 illustrates the fundamentals of a simple timing diagram. Perhaps one of the first things worth pointing out is the desirability of using *graph paper*. This will help you establish a time reference (by assigning a time period for each division) and certainly help in keeping events lined up vertically, which is one of the objectives.

The arrow at the bottom of the diagram indicates *time* is going from left to right. It's the only way to go . . . there aren't many things as confusing as trying to use a timing diagram drawn the other way. (Keep in mind that an oscilloscope display is also from left to right with respect to time.)

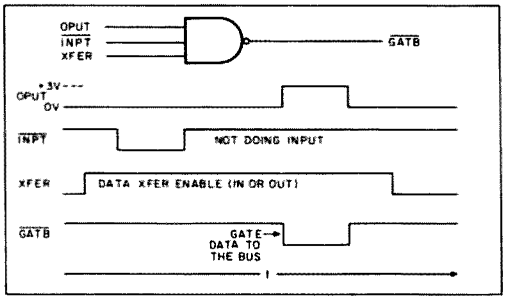

Fig. 1. A simple timing diagram illustrating the output of a 3-input NAND gate.

The diagram illustrates the inputs and outputs of a 3-input NAND gate. Assuming we had the three input signals down on paper our next step would be to generate the output. Remembering the rules for a NAND gate (that is, the output will go low only when all of the inputs are high), we begin examining the input signals from the left. As long as any of the inputs are low, the output will remain high. And, as you can see, the output drops low when all three are high. Signal OPUT ("OUTPUT") is high, indicating an output function is to be performed. $\overline{\text{INPT}}$ ("INPUT" NOT) is high, indicating an input function is not currently being done. And, XFER ("Transfer") goes high to enable the data transfer. The output signal, $\overline{\text{GATB}}$, ("Gate to Bus" NOT) is low when we're gating data to the bus.

One more point before leaving this basic diagram. Notice the comments. Now, it doesn't matter if you put comments with the signal mnemonic or with the waveform, as shown. But, it's a good idea to do it . . . and for a very good reason. This timing diagram is to the hardware man what a program and/or flowchart is to a software man. All of them will be easier to read and understand by others (and yourself, a year from now) if there are comments included. (By the way, the reference to "hardware" and "software" shouldn't imply that this discussion is aimed toward computers. We're dealing with *digital electronics*, and that covers a wide range of equipment and applications.)

Timing Diagram Generation

It was evident from Fig. 1 that we needed to know what the input signals were before we could start. This will, of course, hold true for any timing diagram we wish to generate (i.e., the inputs will be our "known" values, and the other signals – including the output – will be our variables, or "unknowns").

We have three signals coming into the circuit shown in Fig. 2. These are Θ1 (Phase 1), Θ2 (Phase 2), and $\overline{\text{RST}}$ (RESET NOT). As you can see, this circuit has a flip flop, and it is very important that you establish in the beginning the state of that flip flop (either set or reset). Note that $\overline{\text{RST}}$ goes true (low) in the beginning to put the flip flop in a reset condition. (And, as part of the "comments" in this diagram, the arrow illus-

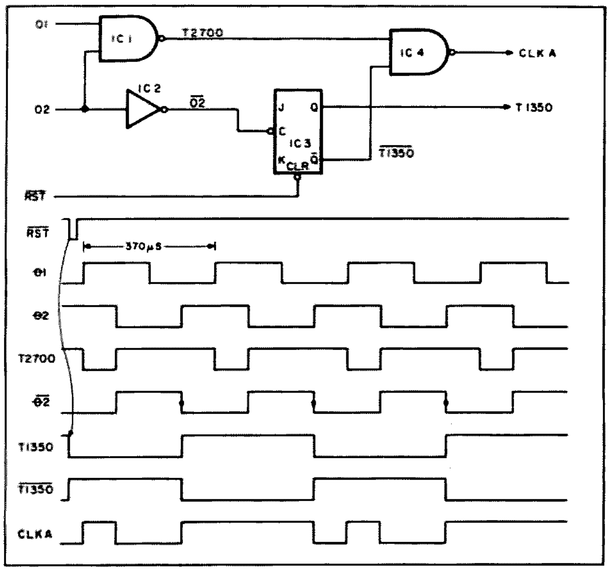

Fig. 2. Generation of a nonsymmetrical clock.

trates this.)

As a suggestion, why don't you take a piece of paper and cover the waveforms below the three inputs, and we'll see if you can anticipate the outputs as we go along (or better yet, draw them on the paper).

Θ1 has a period of 370 microseconds. If you grab your handy-dandy little calculator and take the reciprocal of that, you should come up with a frequency of 2700 Hz. The ANDing of 01 and 02 (through NAND gate IC1) produces the signal T2700. So much for IC1 ... and doing it first was strictly arbitrary. Now, let's take the inversion of 02 (through IC2) and generate the clock for the JK flip flop. On the trailing edge (or "down-clock" or "one-to-zero transition") of $\overline{02}$ the flip flop will change state. It started off in the reset condition (because of $\overline{RST}$) and is clocked set (i.e., Q output high, and $\overline{Q}$ low) on the first trailing edge of $\overline{02}$. And, as you can see, it is toggled (change of state) two more times during the duration of the diagram. The outputs of the flip flop are labeled T1350 and $\overline{T1350}$. The signal names in this case are derived from the frequency of the output, which is 1350 Hz. (The flip flop divided the input frequency of 2700 Hz by two.)

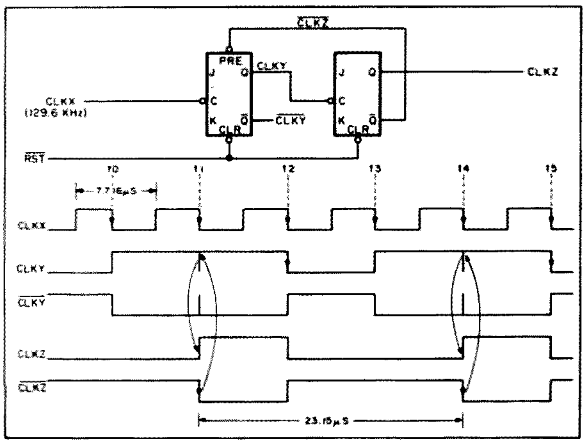

Fig. 3. A divide-by-three circuit.

In order to complete the timing diagram for this circuit, we need to AND together (through NAND gate IC4) the signals T2700 and $\overline{T1350}$. Once again, remembering the rule that the output goes low only when the inputs are both high, we generate the signal CLKA (which is, of course, a nonsymmetrical clock, or signal).

Fig. 3 is an interesting circuit, a divide-by-three. Note that in this case we didn't show the reset signal ($\overline{RST}$) in the timing diagram. Regardless, it's very important that you establish the starting conditions for the flip flops (either set or reset). The labeling of various timing points (t_0, t_1 ... t_5) can be very useful for reference when discussing the diagram. Also notice the "comments," the period of the input waveform (7.716 usec), the period of the output waveform (23.15 usec), and the arrows indicating which transition caused which change of state. The divide-by-three function of the circuit is evident when you see that it took three cycles at the input to develop one full cycle at the output. (If you haven't seen this circuit before, and you find it interesting, it's suggested that you examine it more closely, because it is definitely a tricky little devil!)

Fig. 4 is an "exercise" circuit for those of you who would like to try your hand at generating a diagram from scratch. The "answer" (timing diagram) is shown in Fig. 6. Assume that all three flip flops are in a reset condition initially, and the input frequency of 10.8 kHz is a symmetrical square wave. (NOTE: Have at least ten full cycles of the input signal across the page.)

Interpretation

There are several techniques regarding timing diagrams which haven't been mentioned (but are very common) and will help you in interpreting others. For example, we've been using the bar (or vinculum) over the signal mnemonic to indicate the not term (e.g., $\overline{INPT}$ = "INPUT NOT"). There are several methods in use today for representing the true and false terms in signal notation. Most of them are listed in Table 1.

Fig. 5 illustrates several techniques used to indicate various conditions or states. The first line (DAL 0-7) represents the data and address lines of an eight bit computer. The crossing over of the lines simply indicates that the data and address will be either ones or zeros. This is especially true for multiple lines (as per the example) but can also be used for a single line. The signal called SYNC in the second example is depicted with a broken line, which means that the signal may or may not occur at that particular point. The third line (ADDR) illustrates the "settling time" for a signal. (Settling time is the time it takes for a signal to become stable after being applied to a line or bus.) This is of primary concern when the signal is initially applied to a

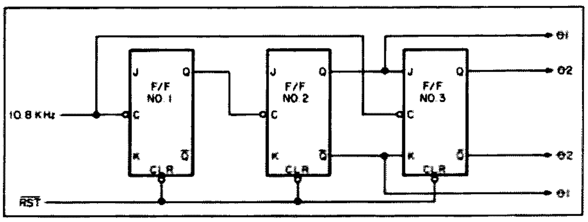

Fig. 4. Exercise circuit.

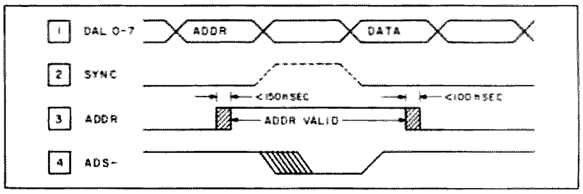

Fig. 5. Some miscellaneous techniques.

line, and therefore the fourth line illustrates another method of showing this, but only at the beginning of the signal.

Summary

Timing diagrams are just one of several useful tools for evaluating, designing, and analyzing logic circuits. It's like anything else ... the more you use it, the better tool it becomes.

If you've been waiting for the punch line regarding "the illogical characteristics of logic circuits," I'm afraid there really isn't one. But, there are times during the course of troubleshooting a digital monster that I (and others) have been known to throw up their hands and scream, "Is there really anything *logical* about this mess!??" Usually, after sitting down and analyzing the "mess" (with a timing diagram, or other means), we find that there is. ■

High True Condition	Low True Condition
STRB+	STRB-
STEP	$\overline{\text{STEP}}$
EADR	NEADR
CRST	CRST'
INTF	INTF L
INIT	*INIT

Table 1. Examples of signal notation.

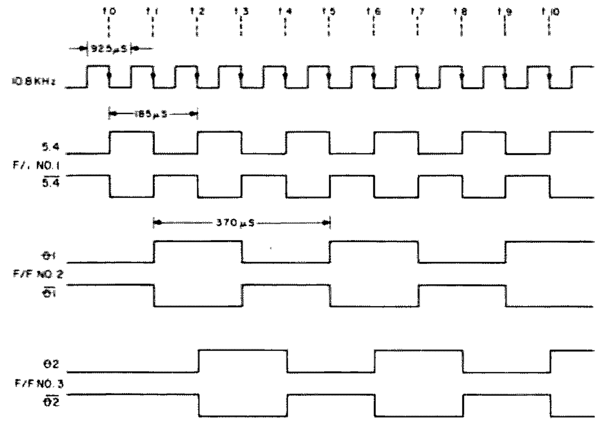

Fig. 6. Timing diagram for exercise circuit. Hopefully your diagram came out the same as the one shown here. Let's discuss it briefly. Flip flop #1 divided the input frequency by two, and we came up with 5.4 kHz. Flip flop #2 divided the 5.4 kHz by two and we now have a frequency of 2700 Hz. In order to make this circuit work you must take the input conditions to flip flop #3 prior to the trailing edge of the t_1 clock pulse (i.e., a low should have been clocked to the "Q" output, as shown here). The high output (Θ1) from flip flop #2 won't be clocked into flip flop #3 until clock t_2. This circuit has generated a frequency of 2700 Hz at four different phases. Consider signal "Θ1" as 0° Phase, and "$\overline{Θ1}$" will be the 180° Phase. "Θ2" is 90° removed from 0° Phase (and is therefore the 90° Phase). Signal "$\overline{Θ2}$" is 180° removed from 90°, and must therefore be the 270° Phase.

Eight Trace Scope Adapter

--test accessory for digital timing

Probably the most frustrating problem faced when designing digital circuitry is control of timing. After working out a design on paper, one usually breadboards the circuit to prove it out. In accordance with Murphy's well-known laws, there will be several logic errors which will then be apparent but very elusive. Depending upon the complexity of the design, the errors may be (but usually are not) easily located and corrected.

A number of tools are helpful in tracking down these problems – the logic probe and oscilloscope probably being the most helpful. A logic probe establishes the steady-state status of various points in the circuit, but tells nothing about pulse widths or repetition rates. The oscilloscope is used to visually illustrate these waveshapes, pulse widths, and repetition rates. What most scopes do not show is the time relationship between pulses at different locations in the circuit. Sometimes this relationship is crucial in searching out a problem that may be caused by "glitches" (extremely short pulses caused by unexpected and unwanted time overlaps). Well-equipped laboratories use special multi-channel logic scopes for this sort of work, but most of us are not equipped with the kilobuck pocketbook required to manage this. Even a dual channel high speed scope requires a considerable investment.

While such a scope would be most welcome in any experimenter's laboratory, most of us must settle for a relatively inexpensive general purpose scope. Fortunately, it is neither difficult nor expensive to build an adapter to display multi-channel logic signals. The adapter permits viewing up to 8 channels of logic signals simultaneously, and thereby examination of the relative timing between them. Although analog waveshapes cannot be displayed (you can use your scope without the adapter for this function), it will show the low or high states, in precise time positions, of any signals present in TTL or DTL circuits.

Almost any general purpose scope should work with this adapter, but it is recommended that it be equipped with a triggered sweep. The viewing of simple repetitive signals without a triggered sweep can be frustrating enough, but attempting to lock onto one of eight channels being displayed may be virtually impossible. If you are using a scope without this feature, I highly recommend that you consider adding a new triggered sweep, even if you do not build this adapter. The attractive scope described by WØACR in *73* (November/December, 1975) includes such a circuit, which could be easily added to any

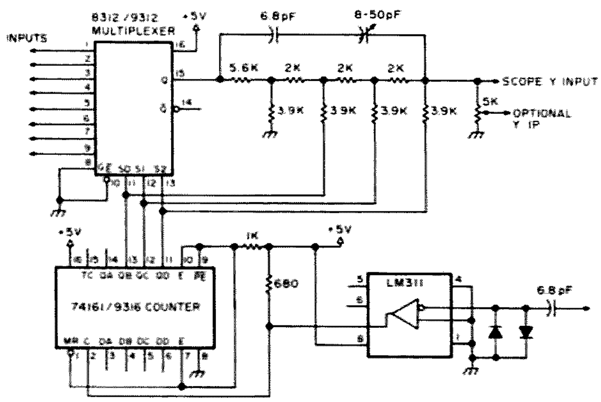

Fig. 1. Schematic.

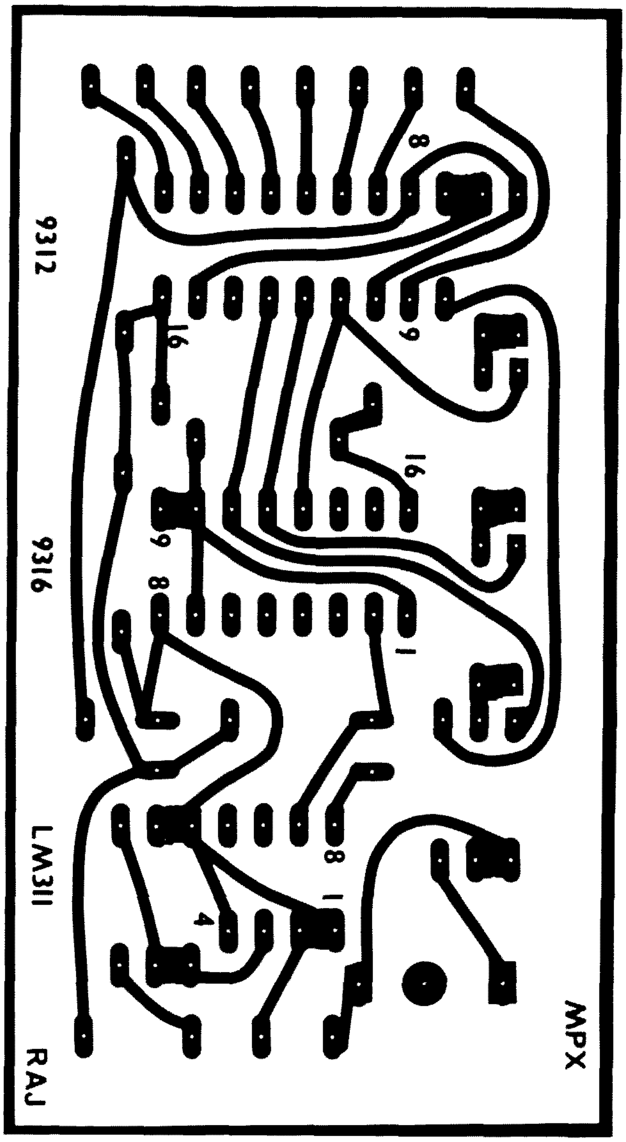
scope. *Radio Electronics* for February, 1975 (p. 143), has another simple 2 IC sweep circuit. Scope bandwidth is not critical unless you are working with really high speed stuff, and a 4 MHz bandwidth will let you examine almost all you need to see. You must have a way to externally trigger the scope sweep, and you will have to find the sweep signal or blanking pulse to permit changing the input channels during the retrace interval.

The circuit itself is very simple: A small capacitor couples the scope sweep circuit to a voltage comparator (you may find it necessary to adjust the size of the capacitor for reliable trace switching). The sweep retrace causes a negative excursion at pin 3 of the LM311, forcing its output to go high. Each time this occurs, a 16 stage counter advances one count. Three output bits of the counter are connected to an eight-to-one 9312 multiplexer, which selects each input in turn, and outputs to pin 15. If most of your work is at the lower frequencies, use the low order 3 bits of the counter, instead of the 3 high order bits shown. When using the 3 high order bits, you may use the adapter with a dual channel scope operating in the "alternate" mode.

A ladder network commonly used for digital to analog conversion is used to position each channel on the screen. The resistors should be well matched (i.e., 1%), but satisfactory results have been experienced with 5% units. If your display is not evenly spaced vertically, try swapping resistors in this network for best spacing. The variable capacitor is used to compensate for the scope input capacitance, and should be adjusted for best waveshapes. The output potentiometer will not be required in most instances, and should not be used unless essential.

Fig. 2(a). PC board (full size).



Note that a 74161 or 9316 synchronous counter is recommended, rather than a 7493 or similar asynchronous type. It is unlikely that propagation delays in an asynchronous counter would result in viewable glitches on the scope in this application, but it is good design practice to always use a synchronous counter where the output states are decoded and fed back to the counter.

The adapter may be built on a small printed circuit board (note the IC polarity!) and installed inside your scope. However, it may be very conveniently enclosed in a small box which can be located near and powered from the digital project, and coupled to the scope via cables. You will need the usual vertical input cable and a sweep-out signal. Many scopes have an "Ext" jack for horizontal input, which is permanently connected to the input of the horizontal amplifier. When the sweep is running, this also happens to be the output of the sweep generator!

Should you experience difficulty in obtaining a stable trace, the sweep circuit may not be advancing the counter properly. Try a

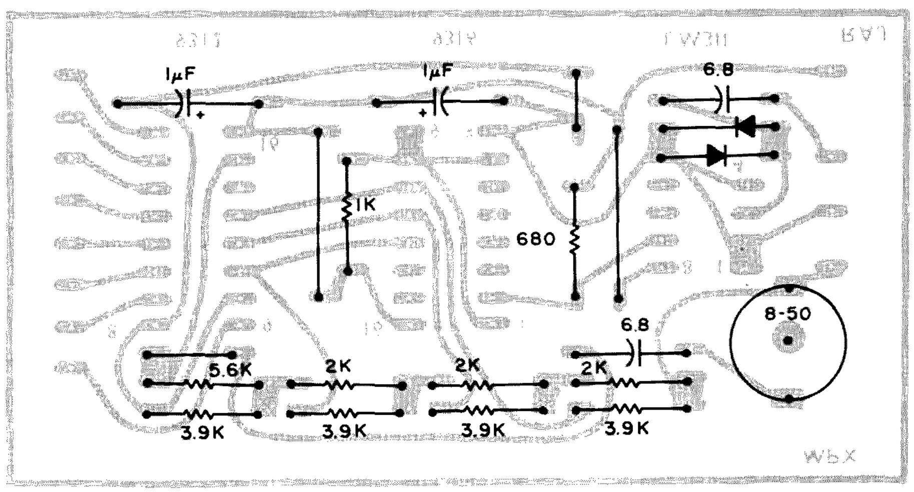


Fig. 2(b). Component layout.

different spot in the sweep circuit first. You may find it necessary to invert the signal by using pin 2 of the LM311 (grounding pin 3) if the signal is reversed in polarity. The 74161 counts on a rising edge, and reverse polarity will cause the channel change to occur in mid-sweep, with obvious visible distortion. You may find experimenting with the size of the sweep input capacitor to be helpful, but be careful to avoid distorting the sweep. The scope will not be as bright as usual, as the trace is being time-shared among 8 signals. A slight adjustment of the brightness control compensates for this. The variable capacitor is adjusted for best waveform using a 10 kHz or higher digital pulse. A 74151 multiplexer is functionally identical, but not pin compatible, with the 9312 unit. The LM311 comes in either a mini-dip or TO-5 package. As the pin-outs are identical, either may be used with the circuit board shown.

Using your multi-trace scope is a delightful experience: You see all of those signals at the same time, and can really tell what is going on. Remember that you must trigger the sweep from the slowest signal you are viewing; otherwise, you will not be able to sync the slower signals. Also, be aware that the inputs are not protected in any way, and connection to potentials outside of the proper logic levels will destroy the multiplexer IC. Protective diodes may be added on the input lines to give marginal security, but care, plus a socket for the 9312, are probably adequate.

The small investment required to construct this unit will be quickly repaid the first time you use it to track down a problem.

Happy hunting! ■

The PROM Zapper

--build this simple PROM programmer

Geoffry W. Kufchak WA1UFE
15 Fourth Ave.
Westover AFB MA 01022

Quite a few articles have been published recently in *73* and other magazines wherein a PROM has been required. Usually a schematic like the one in this article is supplied along with instructions for programming, but not the construction of the programmer. This is the one I built for programming the 8223 PROM used in my CW ID. (See *73*, July 1976, page 58.) The 8223 PROM is a 32 word by 8 bit memory element. It is similar to the circuit in the Signetics *Bipolar Memories* book, but I added a built-in 5 volt regulator and a low current LED to verify the output programming. The switches are also somewhat different. The only power needed is a regulated 12.5 volt supply or auto battery.

Construction

The programmer is built in a 4" x 6" x 2" aluminum chassis. A parts layout is given, but may be altered to suit your own taste, depending on the enclosure used. All wiring is point-to-point, with only one PC board used. The PC board has a socket for the 8223 and also provides solder pads for wiring.

First, lay out the top panel. Then drill the holes for the switches and LM309K. Drill two 7/16" holes and file to a rectangular shape for the IC socket to fit snug. Using the PC board as a template, mark and drill the two mounting holes. Drill a hole somewhere on the panel for the LED and two holes on a side panel for the power connections. Deburr all holes and cutouts. Apply lettering if desired.

Mount all the parts on the chassis with appropriate hardware, using insulated washers where necessary. A few ground lugs will also help. Install the resistors, capacitors and LED first, then wire the output selector switch, using color-coded wire to avoid confusion. Then wire the address and program switches, the Vcc and ground lines.

Operation

Recheck all your wiring and then program according to the following instructions:

1. Connect programmer to a regulated 12.5 volt source.

2. Set the PROGRAM-VERIFY switch to OFF.

3. Insert the 8223 to be programmed in the socket, paying attention to the location of pin 1.

4. Set the ADDRESS switches to the proper word to be programmed.

5. Set the OUTPUT switch to the output to be programmed for the corresponding word.

6. Set the PROGRAM-VERIFY switch to PROGRAM.

7. Momentarily depress the PUSH-TO-PROGRAM switch to program a logic 1. (Do not exceed 1 second.)

8. Set the PROGRAM-VERIFY switch to VERIFY. The LED will light indicating a logic 1 has been programmed. Set switch to OFF.

9. Repeat steps 4 through 8 to program the rest of the chip.

Only logic 1s need be programmed as the chip comes with all outputs at a logic 0. Also, by using the VERIFY position, pre-programmed chips may be tested and a truth table made up. ■

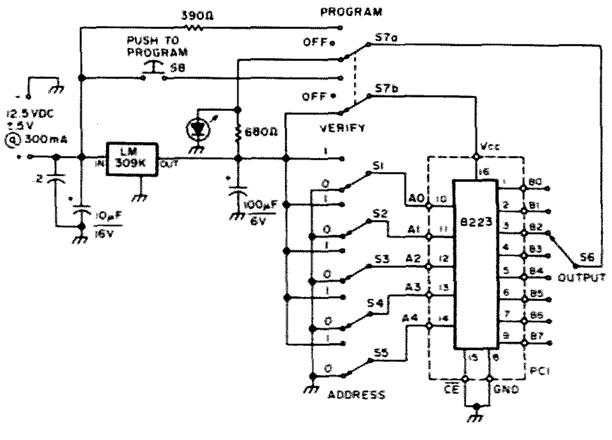

Fig. 1. 8223 PROM programmer schematic diagram.

Parts List

(Most parts available at Radio Shack)

1	LM309K

THE Z-80 REVOLUTION

TDL IS PROUD TO ANNOUNCE THE REVOLUTIONARY Z-80 CPU CARD, AN ALTAIR/IMSAI COMPATIBLE CPU CARD FEATURING THE POWERFUL Z-80 uP PRODUCED BY ZILOG INCORPORATED. WHAT'S SO REVOLUTIONARY ABOUT THE Z-80? A LOOK AT THE FOLLOWING COMPARISONS WILL SHOW YOU:

As you can see, the Z-80 is a very powerful and fast uP - in fact its a NEXT generation microprocessor. And its available to you in a totally compatible format, NOW. Just unplug your current CPU card, plug in the Z-80 CPU, load a program, and you're up and running - with a NEXT generation uP. The power and versatility of the Z-80 is unequalled in the uP field, and it opens the door to tremendous developments in the state of the art. More powerful, faster, and less memory consuming versions of your current 8080 software are just a part of the possibilities the Z-80 provides. (TDL's own 8-K BASIC for the Z-80 will be available in September.)

Each Z-80 CPU kit comes complete with:

- Prime commercial quality boards, IC sockets etc.
- easy to follow instructions
- Zilog's Z-80 Manual
- Schematics
- An easy to understand and apply user's guide
- TDL's Z-MONITOR on paper tape (soon to be available in deluxe PROM version)
- And membership in the Z-80 user's group.

Move up to the Z-80. Only $269.

Comparison of the Zilog Z-80, Intel 8080, and Motorola 6800CPU chips

	Z80	*8080*	*6800*
NUMBER OF:			
Instructions	158*	78	72
Internal Registers	17	7	6
Addressing Modes	10	7	8
Voltage Required	+5	+5,-5,+12	+5
Standard Clock Rate	DC-3MHz	0.5-2MHz	0.1-1MHz
Clock Phases	1	2	2
Clock Voltage	4.2	8.4	4.8
DynamicRAM refresh and timing signals without slowing down CPU or requiring additional circuitry	Yes	No	No
Single instruction memory to memory and memory to I/O BLOCK TRANSFERS	Yes	No	No
Single instruction SET, RESET, or TEST *of any bit in accumulator, any general purpose register, or any external memory location*	Yes	No	No
Single instruction BLOCK SEARCH of any desired length of external memory for any 8-bit character	Yes	No	No
Non-Maskable Interrupt and TTL compatible inputs	Yes	No	Yes
Internal sync of inputs and direct strobe of outputs	Yes	No	No

* Includes all 78 machine code instructions of the 8080A and is therefore capable of running any standard 8080A software without modification.

ADDITIONAL FEATURES OF THE Z-80:

- Up to 500% more throughput than the 8080A
- Requires 25% to 50% less memory space than the 8080A CPU
- Three modes of fast interrupt response plus a non-maskable interrupt
- Outperforms any other microcomputer in 4-, 8-, 16-bit applications

THE FASTEST RAM? The high speed capability of the Z-80 demands an extra-fast RAM to back it up, and TDL's new Z8K RAM board fills the bill. The Z8K is an 8K by 8 static RAM with the fastest access time in personal computing - 215ns. Its the only RAM in personal computing fast enough to let the Z-80 run at full speed with no wait states. If that isn't enough, it also happens to be one of the lowest powered RAMs around as well. Only 150 ma typical current load on the 5V supply. That makes the Z8K run cool -and perfect for battery standby operation as well. Other so-called "low power" 4K RAM boards can't compete with these specs. Its the perfect match for the Z-80, and its features and low cost make it a perfect match for ANY uP. (It's fully Altair bus compatible of course...) Price: Only $295

WHAT ABOUT QUALITY? All TDL products share one thing in common - exceptionally high quality. The quality starts with engineering that is dedicated to keep your system state of the art at the lowest possible cost. Consider also the "Qual Division" whose ONLY purpose is to keep TDL's products the best in the industry. And our products use only the finest boards available, prime components, sockets for all ICs, gold plated edge contacts and other earmarks of a commercial grade product. And its backed by a solid 90 day guarantee on parts and materials.

SAVE MONEY NOW Order both a Z-80 CPU card, and one or more Z8K RAM boards before September 1st, 1976, and you can deduct 10% on the total cost. Act now while this special offer lasts. (Does not apply to COD orders.)

HOW TO ORDER Just send check or money order, or use your BankAmericard or Mastercharge, and your orders will be shipped to you postpaid within 30 days. COD orders must be accompanied by a 25% deposit. Your credit card order must include the serial # of the card, expiration date, and your order must be signed. New Jersey residents add 5% state sales tax. For more information, send for our free catalog.

Table 1. ASCII keyboard characters which will produce corresponding Baudot characters. Only bits one through five of the ASCII character are used.

Here are some apparently unrelated items to fit together.

1. From what I have heard and copied RTTY-wise, most of us hams are not the world's greatest typists; hunt and peck sounds like the order of the day.

2. The April '76 issue of *73 Magazine* has a great idea article on a RTTY generator by WA6JMM.

3. There are lots of keyboards around but they mostly spit out their dope in ASCII whilst we ply our trade with Baudot.

4. There are splendid circuits for getting Baudot from an ASCII keyboard, but they tend to be exotic and mildly expensive.

If we are willing to compromise our aesthetic sensibilities just a smidgin, accept hunt and peck as a legitimate life style, we can take the ASCII keyboard, rearrange the key caps a bit, throw away bits 6 and 7 of the ASCII code, and feed the result into the versatile TTY generator of WA6JMM.

The accompanying table shows the cross referencing of Baudot to the first five bits of the ASCII code. Naturally you will have a lot of keys on the standard ASCII keyboard that you will have no use for as the entire Baudot budget uses but 31 keys. Notice that at least two of the ASCII keys will produce the same Baudot code group character, which gives you some choice as to how to lay out your revised keyboard. ■

Simple Graphics Terminal

--using inexpensive surplus equipment

Several designs have been presented in the past that would, in one way or another, allow the display of graphical data on a CRT. Although these several approaches will accomplish the stated objective, each has the shortcomings of requiring the builder to fend for himself when it comes to the actual output device to be used. The graphics display described in this article takes advantage of a group of ready-made subassemblies, which when interconnected and properly interfaced with the graphics driver portion of this project, will result in a first class graphics display with capabilities far in excess of those attainable with a simple oscilloscope adaptation or a raster-scan television readout device.

To illustrate that point, consider the following. The raster-scan home television type display, such as that used in several popular alphanumeric displays, can be used. But, the display is overly complicated and will appear as a connection of blocks rather than as pure line segments. Consequently, since graphics display implies a random display, a single memory cell is required for every defined location on the screen, with the block size determining the maximum number of locations and hence, the resolution. The finer the detail required, the smaller the blocks and the more memory cells required. If the complete screen is to have 256 elements or blocks, these individual units could be defined by four bit X and Y addresses and 32 bytes of 8 bit memory. The resolution in a display with these few points would be terrible.

An 8 bit microprocessor works best with multiples of 8 bits. If we, therefore, made a display incorporating an 8 bit X address and an 8 bit Y address, it would fit nicely and be easy to work with. This display would be of fairly high resolution since it now has 65,000 discrete locations. The only complication is that it will require 8K bytes of memory to store, regardless of the picture being displayed. This will always be the case in any digital storage system. The computer must account for every dot on the screen (65K) and, depending on whether there is a one or a zero stored in the memory location defining that spot, it will make it either black or white. Additional information is

required if gray tones are involved.

A much better system is one which incorporates this same high resolution but does not have to provide storage for anything other than the actual displayed points. The one described here is just such a system.

What Is Graphics Display?

Everybody knows what a graphics display is, right? We all know that a graphics display will allow us to observe phenomona in that familiar Etch-A-Sketch format drilled into us since kindergarten days. Using appropriate input signal conditioning, a graphics display can be just about anything we want it to be . . . from a simple tic-tac-toe pattern to a very complex schematic or logic diagram. We can even play games such as Space War and tennis, display a graph of the current stock market trends, plot temperature and humidity, and on and on.

That's terrific. Everyone should have one, you say? Agreed. The following paragraphs will describe, in sufficient detail, a method whereby the average experimenter can acquire all of the parts and subassemblies needed to construct just such a device. Basically, this graphics display consists of a group of ready-made subassemblies which, when modified per the instructions contained herein, will result in a very high performance X-Y display. The readout device is a 12" diagonal TV-like CRT with a very bright green-blue trace. This CRT has a medium persistence, which is desirable in the interests of flicker reduction. Additional electronics are described to transform the output instructions from any microprocessor into the analog voltages and positioning signals used to actually produce the various line segments that will make up the desired display of information.

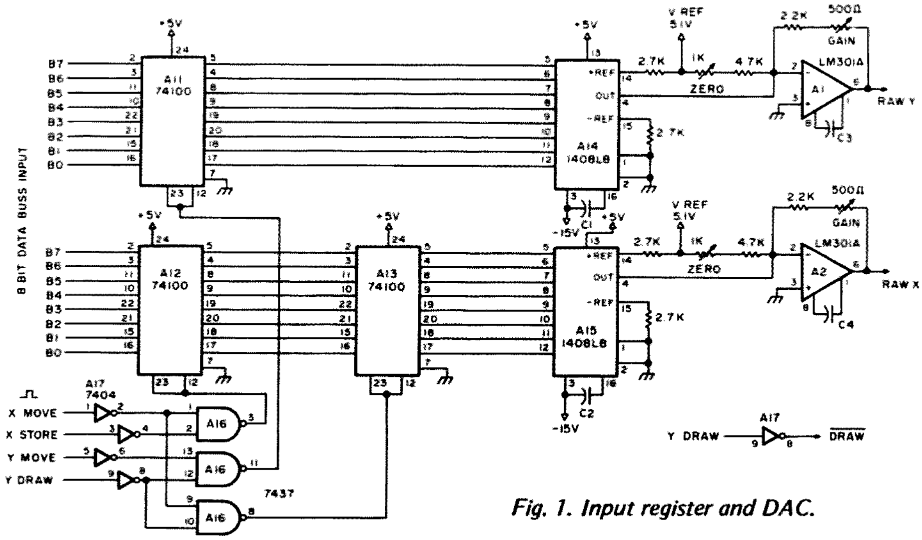

Fig. 1. Input register and DAC.

It should be noted that this article and the graphics display described are the result of the joint efforts of the authors to pull together the many bits and pieces of pertinent information and ideas which abound in the field today. We've drawn on ideas, and in some cases used portions, of previously described circuits to arrive at the final configuration presented here. Our only claim to originality is that we have integrated these various data into a workable, practicable and AVAILABLE piece of equipment intended to do a specific task well, but also have a degree of expandability for new techniques of the future.

So much for the commercial. Now it's time to get on with the description of the project. We'll start with the basic CRT display, since that is the easiest portion. What could be easier than simply sending off an order for a couple of boxes full of already constructed gear and waiting patiently for the order to arrive? Well, there's a wee bit more to it than that, but not much. Suntronix Company (Londonderry, N.H. and Lawrence, Mass.) is once again selling a package of electronic subassemblies that include all of the basic electronic items needed to construct the X-Y display portion of this project. These subassemblies include all of the power supplies, both high and low voltage, the vertical and horizontal deflection amplifiers, a special yoke for the magnetically deflected 12" CRT, four PC cards, a chassis and base to hold these subassemblies and a neat enclosure to hide all of the above. Also included in the package price is a keyboard, ASCII encoded, with an enclosure that fits nicely with the rest of the equipment. Complete data in the form of schematic diagrams for each subassembly is included. As received from Suntronix, these subassemblies will interconnect without major modification to provide the basic X-Y display. So, first thing to do is fire off an order to Suntronix for the complete package of subassemblies.

Now the hard part. You must decide whether you want to build the CRT driver from scratch or order one from Suntronix. Whichever route you choose, you should read the following technical description anyhow, so put off the hard part (the decision-making) and continue to read.

CRT Graphics Driver

The graphics driver is the interface between the actual display and the microprocessor. It translates the binary coded coordinates presented to it through software routines to analog voltages which position the CRT beam appropriately. This driver is a fairly simple system designed to draw line segments with a very high degree of resolution, yet requires only beginning and ending cartesian coordinates to define that line segment. For example, a line running diagonally across the CRT screen from upper left to lower right (-X, +Y to +X, -Y) requires only four eight bit bytes to define the line. Beam position is proportional to the analog voltages applied to the inputs of the deflection amplifiers. The digital to analog converters (DACs) in the graphics driver convert the eight bit coordinates to the analog voltages they represent. Continuous scanning of a series of these values connects many individual line segments to produce the desired figures or pictures or whatever. Additional circuitry is included to assure a relatively uniform beam intensity regardless of where the beam is commanded to go. Also, blanking of unwanted beam

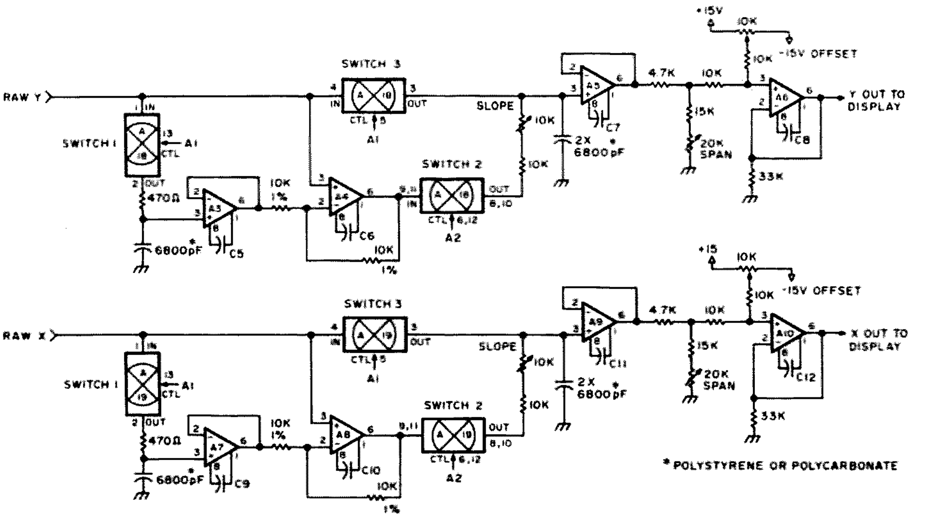

Fig. 2. Vector generator. Note: A1-A10 – pin 7 to +5 V, pin 4 to -15 V; A16-A17, A21, A22 – pin 14 to +5 V, pin 7 to ground; A20 – pin 16 to +5 V, pin 8 to ground.

movements is included.

Input Registers and DACs

The graphics driver has been designed to be driven by any eight bit microprocessor such as the 8008, 8008-1. It is compatible with any faster eight bit machine so long as the software scanning routines do not exceed the processing and analog conversion time of the driver. Though somewhat modified, this circuit is based upon a similar design by Hal Chamberlin and presented in the first three issues of *TCH*. Basically, the design is a software graphics driver. Computer instructions are used to output the binary position coordinates to the driver eight bits at a time; first an X position, then a Y position. Together, these sixteen bits represent the X,Y beginning position of a line segment. Next, the computer outputs the X,Y values of the ending position of that line segment and the driver unblanks the CRT beam to allow display of this motion between the start and end positions. Since this display is software driven, the total number of displayed lines is a function of the computer's speed. Refresh of the display is accomplished by having the computer scan the coordinates continuously. If there are too many points, the display will appear to blink or jitter. The CRT's P31 phosphor helps to correct this condition by allowing more time between refresh cycles. This will be helpful to people with slow computers!

Four instructions are used: Xmove, Ymove, Xstore and Ydraw. They are actually four output strobes from the computer which are enabled by the transfer of position data to the graphics driver storage registers. When Xmove (the I/O instruction outputting data to whatever output port is chosen) is executed, the contents of the microprocessor's accumulator are transferred via the eight bit data bus to an eight bit register, A13. Next a Ymove is executed and the accumulator contents are transferred to A11. Connected to these registers are two eight bit DACs, A14 and A15. The converters free run and will follow any change in value of the input registers. Within a few microseconds of data input, the respective raw X and raw Y voltages will have settled out and now represent, in analog form, the digital X and Y coordinates from the computer. As the instructions implied (Xmove and Ymove), the beam position changes to follow this new input but is not displayed since the beam is blanked during this period.

The actual analog voltage is a function of the 1408L8 DAC. This device behaves like a programmable current source set by the reference current at pin 14. In this particular design, the reference current is approximately 2.0 mA. Binary inputs to the DAC provide the equivalent fraction of the reference current at the output. For example, if the input to the DAC were 00100000, the output current would be 32/256 of the reference current. This signal is more useful and manageable in voltage form. That's the job of op amps A1 and A2. These op amps are configured as current to voltage converters with adjustable gain and offset. With an input of 00000000 binary, the output should be adjusted to a value of -2.5 volts. Adjusting the gain and offset trimmers alternately will produce the desired results. Conversely, an input of 10000000 should produce an output of +2.5 volts. This voltage range is not compatible with the display deflection amplifiers as received, and will be scaled by additional circuitry in the display driver electronics.

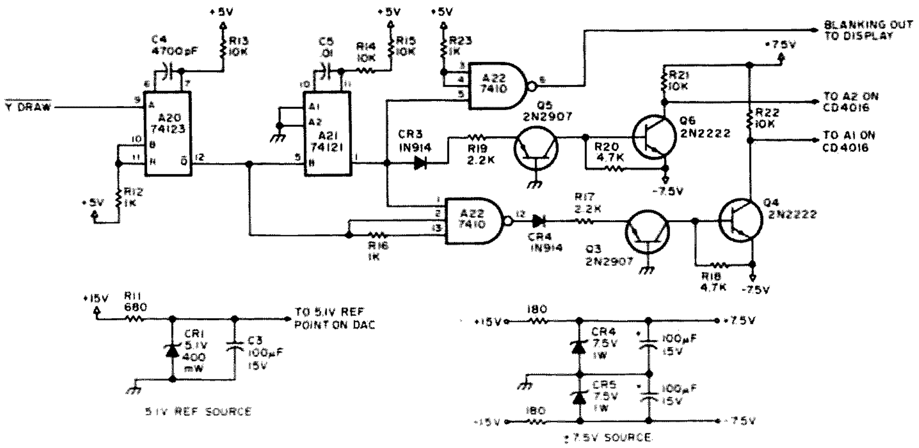

Fig. 3.

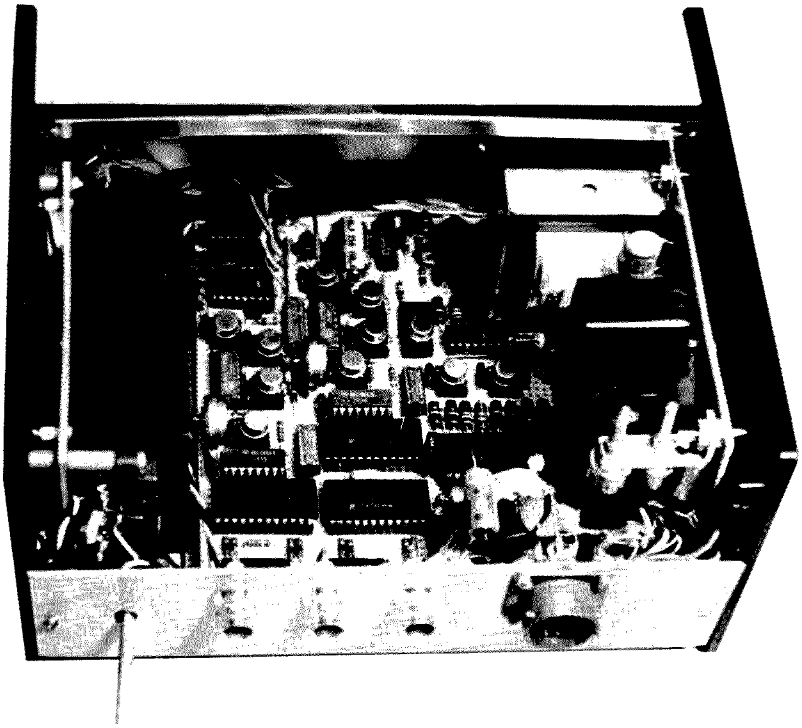

Vector Generator

The raw X and raw Y voltages from the DACs go to the vector generator which uses CD4016 quad analog switches. These switches are controlled by Q1, Q2, Q3, and Q4, a level shifter that changes the voltages from TTL levels to MOS levels, required by the CD4016s. Each switch section consists of a signal input and output terminal and a switch control terminal. When this control terminal is at +7.5 volts, the switch is on, and when the control terminal is at -7.5 volts, it is off. A DM8800 level shifter could be used in place of the four transistors and associated components if you can find it. The Suntronix graphics driver uses the transistor version in the interest of simply being able to obtain the parts readily.

In the quiescent state, switches 1 and 3 are on, 2 is off, and the output of the vector generator is equal to the raw input voltage. When a Ydraw is executed, A20 fires for approximately 20 microseconds and turns off switches 1 and 3. During this one shot period, raw X and raw Y voltages are settling toward the new input values loaded into the registers. These values correspond to the end point of the line segment. The display is still in a blanked state, and with switches 1 and 3 off, the vector generator is acting as a sample and hold circuit in a hold condition with the output constant.

When the first one shot times out, it fires A21 which has a period of approximately 100 microseconds. While A21 is on, the beam is unblanked, switch 2 turns on, and switches 1 and 3 remain off. In this state, the integrating capacitor at A9 starts charging through switch 2 along an exponential curve. Even though this voltage is actually 2 times the new raw value minus the original raw value, the one shot's period is adjusted to time out at the correct end point voltage and provide the appearance of a straight line. The fact that the output voltage changes along an exponential curve is irrelevant as long as both axes are identical. At the conclusion of this one shot period, switch 2 turns off, switches 1 and 3 turn on, and the display blanks again. The output voltage readjusts itself to exactly the new voltage through switch 3.

The driver electronics, to this point, have been set to produce minus and plus 2.5 volt signals for octal inputs of 000 and 377 respectively. This five volt magnitude is incompatible with the deflection amplifiers as purchased. The purpose of A6 and A10 is to scale and offset the vector generator outputs so they are within 0 to -3 volts as required. Each op amp is configured as a non-inverting summing amplifier. The span adjustment alternates the 5 volt absolute magnitude from the vector generator to 3 volts (plus 1.5 volts to -1.5 volts). The offset pot is then set to produce an offset of -1.5 volts with no signal in. The resulting signal level will be minus 3 volts for an octal 000 input and 0 volts for an octal 377 input. These two settings, as well as the gain and offset adjustments of the D to A converters, are best done by loading single values in the registers and not trying to program an actual display.

The vector generators will need slope and end match calibration. It is easiest to adjust the vector generator if a square with diagonals from corner to corner is displayed. The worst case for the driver, and hence the optimum case for calibration, is the display of a square with full scale coordinates. A square with two diagonals can be drawn with 6 line segments and is illustrated with full scale octal coordinate numbers in Fig. 5. The brute force display method is to write a program which treats each line segment as a separate entity and outputs the display coordinates to the driver sequentially. For this particular square, the program would do successive outputs from the accumulator of Xmove, Ymove, Xstore, and Ydraw, respectively, for the following series of octal coordinates: 000,000,000,377 (line segment 1); 000,377,377,377 (line segment 2); 377,377,377,000 (line segment 3); 377,000,000,000 (line segment 4); 000,000,377,377 (diagonal line segment 5); and 000,377,377,000 (diagonal line segment 6). Repeat continually for a constant display.

This again is the worst case display and requires optimum performance from the driver. End point timing problems will appear either as under- or over-shoot of line segment length and can be compensated by adjusting the end match pot on A21. Slope problems will result in the diagonals of the square not meeting in the corners. Slope adjustments are made with the appropriate pots at A5 and A9. It is important not to

A1-A10	LM301A Op amp

A18-A19	4016 CMOS quad analog switch
A20	74123 One shot
A21	74121 One shot
A22	7410 3 input NAND

All resistors ¼ W 5% unless otherwise noted.
All variable resistors are trimpots or equivalent.

Fig. 4. Parts list for graphics driver.

substitute any operational amplifiers which may have a slower frequency response than the LM301A's because this will compromise the driver's ability to track large changes in input coordinates and will attenuate full scale response. An additional area of concern is power supply bypassing and grounding. The largest ground plane and thickest wire appropriate for connecting grounds will result in the least noise and the cleanest display. Bypass capacitors (.1 microfarad/25 volt) should be placed between supply voltage points and the ground plane at a number of locations on the display driver board. Too many is always better than too few when it comes to bypass capacitors. Make the layout orderly and neat to reduce crosstalk and avoid ground loops. If separate power supplies for the +5 volts, +15 volts and -15 volts are built and connected by a cable, it is a good idea to put extra filter capacitors (100 microfarad or higher/25 volts) on these power lines where they enter the display board. Tantalum capacitors are the best choice but aluminum foil capacitors are adequate.

Now that you know how it works, it has once again come to the hard part; a decision must be made whether to "build or buy." Obviously, the quickest and easiest way to get this fascinating and useful instrument up and running is to purchase the graphics driver and the set of subassemblies being offered by Suntronix Company. Certainly that is not the only way. You may choose to build the graphics driver from scratch. With the printed circuit card available from Suntronix it should be a relatively simple and even enjoyable task. Merely follow the instructions in the following paragraphs and those that come with the PC card.

If you want to build the driver and elect not to purchase the driver PC card, some additional comments are in order.

Much of the electronics on the four PC cards that come with the subassemblies is superfluous when used as an X,Y display. The two 6 bit digital to analog converters previously used for character placement can be eliminated, as well as the actual starburst pattern generator. The only other alteration is to isolate the blanking signal. When these few tasks are completed and external voltages applied where the DAC inputs had been previously, one will have an operational 12" X,Y input CRT all ready for graphics.

Testing the Unmodified CRT Subassemblies

Before any modifications can be made, the operational integrity of the terminal must be established. Even though the refrigerator sized controller necessary for alphanumerics is missing, the unit is capable of self-scanning through a combination of positions and blanking control with the D to A cards as they are. To test the unit, install the four cards. The card closest to the screen is the horizontal DAC and the next card behind it is the vertical DAC. Both cards are identical. The third card in from the tube end is the integrator, clock conditioner, and starburst generator card. Behind it is the digital position and unblanking card. On the back connector, labeled J103, it will be necessary to put in a 1 MHz clock signal and an unblanking signal. The 1 MHz clock, which is required both for the high voltage generation and character position, is applied to pins 8 and 9 (8 ground and 9 high). A suitable TTL circuit to feed the 50 Ohm load presented by the CRT is illustrated in Fig. 6. It is not necessary that it be crystal controlled, but a clock input is required at all times to operate this unit. The unblanking signal is applied to pins 10 and 11 (10 ground and 11 signal in). With the clock signal applied, and -5 volts from pin 11 to ground, turn on the display. A fairly noticeable high pitched tone should be heard. This is the high voltage oscillator. Slowly rotate the intensity control (same shaft with the on/off control), and a pattern should appear. This pattern will appear as though one were looking at ten layers of chicken wire, but it is actually all starburst locations unblanked and displayed. Removing the -5 volts from the blanking input will leave one starburst pattern displayed on the screen in a random location. Repeated applications of the blanking input will make this single pattern appear to jump around the screen.

At this point, initial checkout is complete and modifications can begin. Although not absolutely necessary, it was determined that all of the modifications to this terminal could be carried out on the four PC cards. The easiest approach is always the preferred method when dealing with surplus electronics because of the numerous design revisions such equipment has had over the years. The latest schematics are always hard to find.

TTL Level Blanking Input

One of the first modifications necessary is to change the blanking level input from the previous level of -5 volts into 50Ω which is inconvenient to use. This negative voltage is an external requirement only. From there it feeds a level translator on the integrator card which converts it to a +4.5 volt blanking level compatible for use in the digital logic of the position and unblanking board. After transferring through all the logic, this

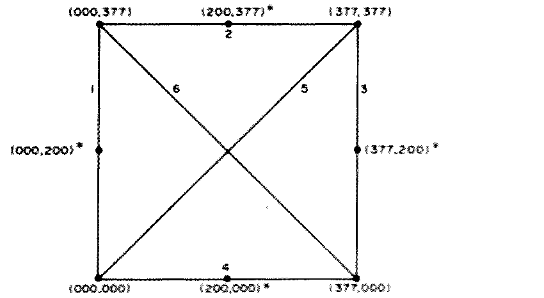

*Fig. 5. Example of a square for calibration. Note: Reference numbers refer to line segments. *Locations given for example only.*

signal leaves the board as an unblank to video amp signal on pin 3 of connector J107 on the base of the card. Between terminal E31 (connected to pin 3) and E30 is a jumper. By removing this jumper and attaching a separate TTL level input to terminal E31, this unblanking option can be externally controlled. The card itself cannot be discarded and has to be inserted for the unit to be operational. There is additional logic on this card necessary to generate the high voltage for the CRT. This concludes the modifications necessary to allow external blanking.

Eliminating the Starburst Generator

The starburst generator is located on the integrator and clock conditioner card. The output of this generator feeds directly to the video amplifier and must be disabled or a moving starburst will be displayed rather than a line segment when the beam is moved. This simple modification can be accomplished by removing a transistor, Q9, and cutting a tape between pin 15 and the junction of

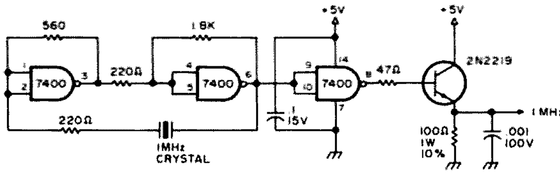

Fig. 6. 1 MHz oscillator. All resistors ¼ W 5% unless otherwise noted.

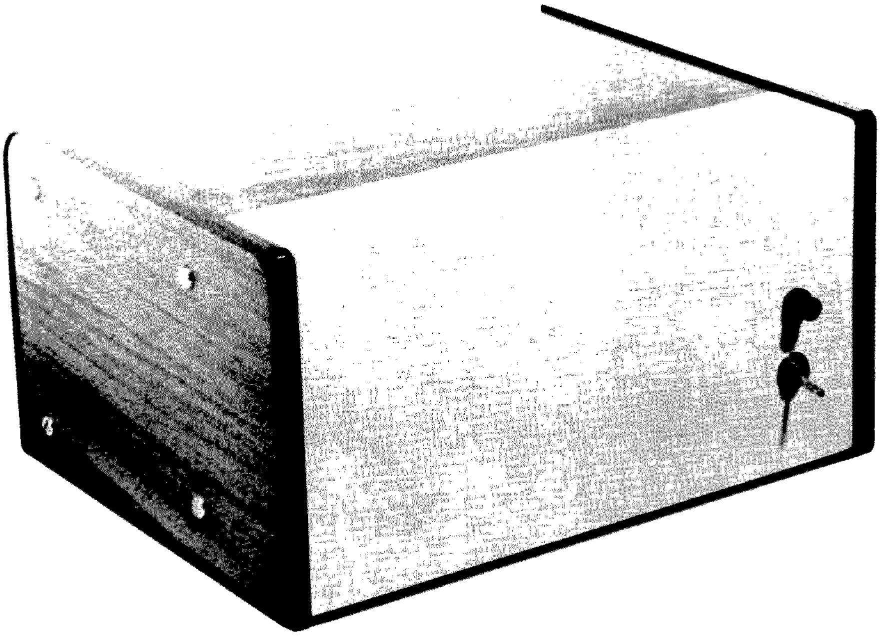
R21 and the emitter of Q8. By cutting these two signals to the video amp, we are eliminating a 2 bit D to A converter which continually causes the beam to trace a starburst pattern. What is left is a single dot on the screen whose position is completely controlled by the vertical and horizontal deflection voltages generated on the vertical and horizontal D to A cards. As in the previous case, there is other circuitry on this card, such as the clock conditioner, which requires that the card be inserted for the display to be used. This concludes the integrator card modifications.

Vertical and Horizontal Deflection Inputs

The modification to the deflection amplifiers to allow external deflection voltage input is indeed simple. It essentially means throwing away the two D to A converter cards and applying the external input voltages directly to the connector pins. Unfortunately, getting at these pins is difficult and requires removing the high voltage section. An easier method is to disconnect the DAC outputs on each card and attach the external input on the card in its place. The two cards are identical and require the same modification. Each of these boards is a 6 bit digital to analog converter card. The output of the converter is jumpered from terminal E1 to terminal E2. Terminal E2 is also the output pin M on the base of the card. By removing this jumper, the card electronics is disconnected. A coaxial cable can then be attached to terminal E2 on each board to provide the external input. There is plenty of foil grounding area on the cards to which to solder the coax shield directly, and this serves to reduce input noise considerably.

Warning! With all these modifications, the automatic blanking and sweep circuits of the unit have been defeated. This is of no real consequence, but extreme care must be taken not to damage the CRT. The blue-green phosphor is exceedingly bright, and has to be protected from over-intensity which would otherwise burn a permanent mark on the screen. The graphics driver is designed to prevent this occurrence, but at this stage of the checkout process, none of those protective circuits is involved.

It is important to check the display terminal as it stands now. For all practical purposes, it is a 12" oscilloscope at this point and can be checked out as such. The deflection voltage which must be externally applied to both horizontal and vertical inputs is in the range of 0 to -3 volts. It is of the *gravest* importance that the polarity not be reversed or the magnitude exceeded on these inputs. Schematically, it would appear quite acceptable to do this, but in actuality it is disastrous. The deflection yoke resistance is less than .1 Ohm and demands considerable current to drive it. This deflection current is directly proportional to the input voltage. When a 0 to -3 volt signal is applied, the deflection current sweeps from -2 Amps to +2 Amps approximately. The low voltage power supply is a real brute capable of better than 10 Amps. When voltages of other than the optimum are applied, the deflection will try to follow. The unfortunate problem is that the manufacturer didn't build the deflection amplifiers to handle this much current and



they go poof! They, of course, never were concerned with this problem because the D to A converter cards could not have produced these voltages. It is a wise idea, if this display is not going to be permanently attached to a driver of some sort, to put some clamping and voltage limiting circuitry on these inputs. It wasn't without hard reality that these facts were determined.

To continue the deflection checkout, it is necessary to have two 3 volt supplies. Two pair of "C" cells in series are quite adequate and safest. Fig. 7 is a sketch of these checkout requirements. Each 3 volt supply should be placed across a 10k Ohm pot with the positive side of the battery connected to the display chassis ground. The output voltage at the wiper of the pot will go from 0 to -3 volts with respect to chassis ground. When this fact is agreed upon, one can feel fairly safe in attaching this variable voltage to the horizontal and vertical inputs as described previously.

Now comes the acid test. Using a meter, set each input to -1.5 volts. This will correspond to a null or no deflection condition and should place the beam position directly in the center of the screen. The blanking input should be ungrounded and open and the 1 MHz oscillator turned on. Very carefully turn on the display, but don't immediately rotate the intensity adjustment. After allowing about 30 seconds warmup, and taking note the high voltage is on, slowly increase the intensity. Eventually there will appear a single dot near the center of the screen. Do not make it too bright because it will burn the screen. When this phase is accomplished, increase the voltage applied from the battery sources and notice that the beam moves proportionally with the voltage change. The horizontal input obviously is driving the beam in an X direction from left to right and back, while the vertical is driving it in the Y direction which is up and down. If both pots are turned simultaneously, the beam will move at an angle.

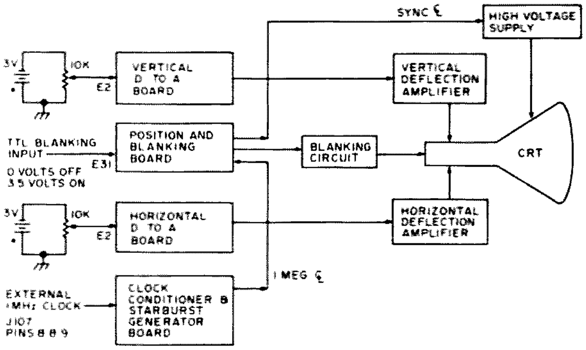


Fig. 7. Deflection amp subassembly checkout.

That's all there is to it. Be sure to use coax between the driver and the horizontal and vertical inputs and watch the ground loops. Properly adjusted and imaginatively programmed, this graphic display will very quickly become your favorite form of entertainment as well as an extremely useful tool.

The authors will be happy to hear from any who build this unit. We'll try to answer your questions as quickly as possible as fully as possible, but please, enclose an SASE when requesting answers. That will insure a reply. ■

by John Craig

I/O REPORT

"*73* West" is located on a hill outside of Lompoc, California, overlooking the beautiful Valley of the Flowers and in the "backyard" of Vandenberg Air Force Base. Because of this vantage point, we're treated to two beautiful sights not found in many spots around the country. One is the panorama of flower fields laid out below us during the summer; the other is the spectacular launching of spacecraft from Vandenberg. Another benefit derived from living here is that the weather never demands snow chains on our cars or galoshes on our feet . . . as you might find in other parts of the country (e.g., New Hampshire).

I couldn't have picked a better "in between" location for keeping track of the computer field here in California. San Francisco, and the "Silicon Valley," is about 4½ hours away and the tremendous amount of activity in the Los Angeles area is only 3 hours away.

We've set up a computer center here for evaluating and testing all the new microcomputer systems and peripherals coming on the market. The objective is to be able to better serve you, the reader, and manufacturers, by having additional facilities for checking out these units. I'm going to be generating both articles and new product reports on systems, options, and peripherals. And, not incidentally, the editorial functions for "I/O" are being taken care of here.

Aside from the systems which have been passing through regularly, I have my own personal home computer, which is of the wall-mounted variety. It's a Varian Data Machines model V-73 which, as I'm sure you're all aware, is fast becoming one of the most popular home computer systems among hobbyists. (Actually, I recently formed a user's group of privately-owned Varian computers and it turns out that there are only two other V-73s owned by individuals in the entire country . . . that I know of, anyway.) It may not be the most practical home system (because of the cost), but you can rest assured that it is *the* machine for *73 Magazine*! Varian was undoubtedly thinking of us when they gave it the 73 model number, right?

The V-73 is a microprogrammed computer. Through the use of ROMs, as a control memory, it is set up to emulate an earlier Varian computer . . . and through the use of a Writable Control Store board (which is equivalent to Erasable Programmable Read Only Memory . . . EPROMS), the machine can be programmed to emulate *any* computer. I'm in the process of developing the firmware (microprograms) to emulate the 8080 . . . so I can run all that software being developed out there.

If you haven't already discovered the "thrill" of getting your kids turned on to your computer, then maybe you should consider yourself lucky! Actually, I'm just kidding . . . one of the reasons I have a home computer is to introduce my kids to the fun. (They do have a habit of tying the machine up, and we may be seeing the beginning of a problem in home systems — a problem which will very likely be resolved by developing time-share systems for the home computer of the future.) One of the most popular programs run on the Craig system is a game called Qubic, and here you see my daughter Sheri tying up the machine playing it.

User Groups

As I mentioned earlier, I own a Varian Data Machines computer, and I have formed a user's group (of about ten people). By doing so, I've definitely increased the potential of my machine. We swap parts, software, and quite often some very good ideas. Regardless of what type of computer you have, you can reap the same benefits by checking around and seeing if a group has been formed for your particular machine. And, if one hasn't been formed, give some thought to starting one. This can be done by looking through some of the computer hobbyist newsletters and finding people with the same computer as yours. Be prepared for a little work if you decide to start one. But, once it's going . . . no problem . . . you just become another member.

If you know of any user groups which have been formed, drop me a line and we'll publish them in upcoming issues of *73*. Also, if you have word on any new computer clubs which have started up, let us know about them. We'll be publishing a list of clubs soon, too.

Dr. Dobb's Journal of Computer Calisthenics

This could be a big one! Jim Warren, who went to work for the People's Computer Company (PCC) part-time to crank out three newsletters on Tiny BASIC, is now the editor of *another* hobbyist magazine! All of the programs they publish (Tiny BASIC, interpreters, compilers, assemblers, cassette and floppy disc file systems, TV Dazzler software, graphics, music, and on and on) will go into the public domain . . . i.e., it's gonna be free! If you're interested, drop him a line: *Dr. Dobb's Journal of Computer Calisthenics & Orthodontia*, P.O. Box 310, Menlo Park CA 94025.

Baudot — Hardware or Software?

If you've got a Model 15 or Model 19 and it isn't hooked up to a computer, it should be. One of the things which would make me hesitate (if I were in your shoes) would be the interfacing and conversion from ASCII to Baudot and vice versa. Well, the interfacing isn't that much of a problem (see the article by Dick Whipple and John Arnold in the May *73*) . . . and, if you're hung up on the *hardware* for accomplishing the ASCII/Baudot conversion, don't be. There's no need to do it with hardware! The conversion in both directions can be accomplished very easily using two small *software* routines. Once again, I refer you to the above article. Software is really the only way to go for something like code conversion. Keep your eyes open for the articles by Don Alexander (the winner of the Grand Prize at the Altair Convention in March). He has a Model 19 for hard copy . . . and does the conversion via software. But you'll really want to catch his article on the home brew TVT he built. It has split-screen, multiple cursors, scrolling, and several other features. And . . . almost all of it is done with software! Stay tuned . . . it's all coming up in *73*.

The Sinister Microprocessor

If we're blessed with many more TV script writers like the guy who wrote a recent "Six Million Dollar Man," our kids are really going to have some warped ideas. (Incidentally, my family hates it when I occasionally join them to watch the program because of my running comments, such as, "How stupid!!", "They must

Counters Are Not Magic -- They're Simple

--getting right down to basics

There are plenty of counter projects about. You can easily build one of them and it will work fine, first try, too. But how do they actually operate? It was hinted at in "Flip Flops Exposed," Nov/Dec 75, but many readers demanded more details.

My pleasure.

The basic counting circuit has four elements: a decade counter, a latch, a BCD-to-7 segment decoder/driver and a 7 segment LED. One of each will allow us to count from 0 to 9. To count higher we cascade, or add, more elements. Fig. 1 shows the block diagram of a counter circuit.

Let's work backwards. Believe me, it's easier.

Fig. 1. Block diagram of counter.

A Short Course in 7 Segment LEDs

The 7 segment LED is composed of 7 segments, each of which is one light emitting diode. When a current flows through, in the correct direction (it's a diode, after all), it lights. By placing the segments in the proper configuration we can form all the numbers (Fig. 2). Each segment is identified by a letter from a-g.

7 segment LEDs come in two varieties, common anode and common cathode. In the common anode case, all the anodes are connected together internally and we light each segment by touching it to ground. In the common cathode configuration, the negatives are connected together and we light the segments by connecting them to a positive potential. Fig. 2a shows the pin designations.

The Decoder/Driver

Operation of the decoder/driver requires a backstep to discuss binary numbers. You probably never thought about it, but our number system is based on tens (most likely because we have ten fingers or digits). We count like this: 1, 2, 3 . . . 7, 8 9; when we get to what we call ten, we are actually starting all over. Ten is really one-zero. Eleven is really one-one. But, because we use these numbers so often, we gave them special names.

Computers lend themselves to systems or bases other than our base ten. Base two, or binary numbers, are easily comprehended by these infernal machines because they use only two digits, 0 and 1. It takes a lot more room to count great numbers because we only have 0 and 1 to use, but computers digest them readily as 0 and 1 can be ON and OFF, an easy concept for the machine's limited intelligence.

Let's count in binary: 00,01,10,11. That's 0,1,2 and 3 in our decade system. From right to left, our system has columns of units (or ones), tens, hundreds, etc. In binary, we have units (or ones), twos, fours, eights, etc. The chart makes it easy.

The 7446 chip is a BCD (binary coded decimal)-to-7 segment decoder/driver. Internally, it is a maze of AND, NAND and NOT gates, but we don't have to go into that. For decoding purposes, it takes binary coded decimals, the binary numbers we talked about, and converts them to our base ten system for readout on a 7 segment

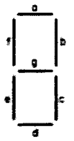

Fig. 2. 7 segment LED.

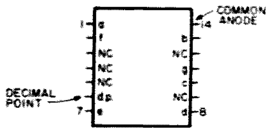

Fig. 2a. Pin configuration. Important note: Not all LEDs use this exact configuration. In some cases the NC pins may be the common anode connection. Check the specs for your LED and use Fig. 4 to connect it correctly.

Binary eights	fours	twos	ones	Decimal hundreds	tens	ones
0	0	0	0	0	0	0
0	0	0	1			1
0	0	1	0			2
0	0	1	1			3
0	1	0	0			4
0	1	0	1			5
0	1	1	0			6
0	1	1	1			7
1	0	0	0			8
1	0	0	1			9

Fig. 3.

LED. As shown in Fig. 4 it has four inputs: DCBA (the backward notation will be explained), and 7 outputs. Disregard the lamp test, RB input and RB output for now.

The input can be any binary number from 0000 to 1111. In our system that would be 0 to 15. Since we are dealing with only one 7 segment display, we are only concerned with 0000 to 1001, or 0 to 9.

Look at Fig. 5. If we put a low at inputs D, B and A, and a high at C, we make the number 0100 (see the reason for the DCBA order). In our decimal system, that is the number 4. The outputs corresponding to that input are highs at a, d and e, and lows at b,c,f and g. Looking at the LED chart, we see that the segments will be blank at a, d and e forming the number 4. Hasn't he got it backwards? Nope. This chip is for common anode LEDs. Thus, any segment assigned a zero, or low, will light. The 7448 chip is available for common cathode LEDs and works in a similar manner, only "negatively."

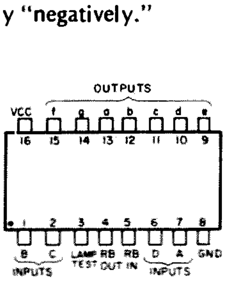

Fig. 4. 7446 decoder/driver (same as 7447).

Let's try another one. The number 8 in binary is 1000. We impose a high on D and a low on B, C and A. The output is then 0000000. All segments are grounded and they light. The number 8!

The Decade Counter

Except in ringalevio we all count by ones. We need something that will count by ones and convert it to binary for our decoder/driver. Not only does it have to count, but it must reset at ten. The 7490 chip was made for this purpose. Every time a pulse from our clock is triggered into the decade counter, it is noted and the output responds with a binary notation.

Fig. 6 shows the 7490 configuration. The outputs DCBA will respond to every clock pulse.

Pulse 1 will give us an output of 0001. The second pulse will yield an output of 0010; the third pulse gives an output of 0011. The chart is known as the BCD count sequence. Very simple.

The 7490 is versatile. The unused R inputs allow many options. By keeping pins 2 and 3 high, our LED will always read 0. Keeping pins 6 and 7 high will give us a constant 9 on the readout. A reset/count chart provided by the manufacturer shows the many choices that are available.

We even have choices for the counter to work properly. Any configuration in lines 4-7 is permissible. It's fun to experiment with all the possibilities, then check back to the chart and see that you were correct in your choices and outcomes.

The 7490 can also be used for other jobs besides decade counting. It can be used for divide-by-ten counting, divide-by-two counting and divide-by-five counting. All require different external connections. In our decade counting application, the output at pin 12 must be connected to pin 1 for correct operation.

The Latch

We are almost done. The 7475 chip is a quadruple bistable latch. Four flip flops, that's all (Fig. 7).

It acts as temporary storage between the decade counter and the decoder/driver. It does have an important function which may be of value in some cases. If the pins 4 and 13 are kept high, the pulses going through will be counted normally. If they are low, the number on the LED is held stationary. To restore normal counting, make it high again. This feature makes it easy to stop the count at any time without doing so at the input. If a situation arises where we are counting and we want to know at what count a certain transaction occurred, all we do is have that event cause pins 4 and 13 to go high.

Not only will we know at what number the event happened, but it will stay visible until we manually reset it to continue its count.

Putting It All Together

All three chips are inexpensive TTLs. They should cost no more than two dollars all together. The price of the LED will be determined by its size. The bigger the segments, the more costly it will be. And, it will also be nicer to look at. That's your choice. There are good 7 segment LEDs available for a dollar. They can be gotten as cosmetic rejects as one segment may be slightly dimmer than the rest. Sometimes you have to look closely to notice it at all. I bought some dollar LEDs of that type and the difference is only evident when all segments are lit and carefully compared.

The schematic is straight-

	Inputs D	C	B	A	Outputs a	b	c	d	e	f	g
0	0	0	0	0	0	0	0	0	0	0	1
1	0	0	0	1	1	0	0	1	1	1	1
2	0	0	1	0	0	0	1	0	0	1	0
3	0	0	1	1	0	0	0	0	1	1	0
4	0	1	0	0	1	0	0	1	1	0	0
5	0	1	0	1	0	1	0	0	1	0	0
6	0	1	1	0	1	1	0	0	0	0	0
7	0	1	1	1	0	0	0	1	1	1	1
8	1	0	0	0	0	0	0	0	0	0	0
9	1	0	0	1	0	0	0	1	1	0	0

Fig. 5. 7446 inputs and outputs.

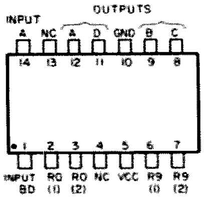

Fig. 6. 7490 decade counter.

BCD count sequence

count	D	C	B	A
	output			
0	0	0	0	0
1	0	0	0	1
2	0	0	1	0
3	0	0	1	1
4	0	1	0	0
5	0	1	0	1
6	0	1	1	0
7	0	1	1	1
8	1	0	0	0
9	1	0	0	1

Reset/count reset inputs				output
$R_{0(1)}$	$R_{0(2)}$	$R_{9(1)}$	$R_{9(2)}$	D C B A
1	1	0	x	0 0 0 0
1	1	x	0	0 0 0 0
x	x	1	1	1 0 0 1
x	0	x	0	count
0	x	0	x	count
0	x	x	0	count
x	0	0	x	count

x denotes either 0 or 1.

Fig. 6a. Charts for the 7490 decade counter.

forward. The pulses from our clock (which we all have by now) are the input. You can try to pulse it by hand, but you won't be able to do it. Your hand is just not sure enough to pulse it once, and only once. Try it. You will see the numbers jump a few no matter how carefully you attempt to give it just one shot. This phenomena is known as switch "bounce." Now you'll understand why flip flops are used as switching devices; mechanical means just CAN'T touch only one time.

Now, back to the other 7446 controls: lamp test, RB input and RB output. Lamp test means just that. If we put it low, all segments light giving us an indication of our LED's condition. When a low is applied to RB output, all segments go blank. It will continue counting though. Going back to a high will light them again wherever it is in the counting sequence. If, while you are counting, you desire to skip 0, put RB input to low. Every time zero comes around nothing is seen.

Cascading Counters

Our counter works fine, but it only counts to 9. For higher numbers we need more counters. And, we have to add them in such a way that the first counter triggers the second after the number 9. And, the third counter must be triggered such that it will work when the second counter goes over 9. This is called cascading.

If you check the operation of the counter, on a slow speed, with a VTVM, you will see that the numbers change on the 1 to 0 change. This is known as "trailing edge triggering." That's important to know. Looking at Fig. 6a, we see that the numbers 8 and 9 have very distinct characteristics. They are the only numbers to have 1 in the D column. If we have a second counter waiting at count zero, it will trigger upon a 1 to 0 change. By taking output D of our first counter and connecting it to the input pin 14 of our second counter, it will count "one" when our first counter passes 9. The first counter will return to 0 and the second counter has a 1. By placing the counters in the proper position we have one-zero, the number 10.

The schematic shows how easy it is to cascade counters. You might also like to make the reset controls a permanent fixture. This assures that the counters all start at zero.

Start counting.

Special thanks are extended to Isaac WN2ALK, who, without regard for his personal safety, came over late one night to supply me with some much needed data. ■

Social Events

MACK'S INN ID
AUG 6-8

The Wyoming - Idaho - Montana - Utah Ham Club would like to announce that the 44th Annual WIMU Hamfest will be held August 6-8 at Mack's Inn, Idaho just 20 miles west of Yellowstone National Park. There will be a full line of activities including our famous breakfast under the pines. Camping on the grounds is available plus motels, cabins and restaurants. Pre-registration is $6 per person, $1 for children under twelve. For registration or more info contact: WIMU, c/o Larry Jacobs WA7ZBO, 5655 So., 4060 West, Salt Lake City, Utah 84118.

OKLAHOMA CITY OK
AUG 7-8

The Oklahoma Ham Holiday and State ARRL Convention will be held Saturday and Sunday, August 7 and 8 in Oklahoma City, Oklahoma. The meeting will feature the largest flea market in the Southwest, special programs, technical seminars, equipment displays, and unique activities for the ladies. For information and advance registration write Oklahoma Ham Holiday, Post Office Box 20567, Oklahoma City, Oklahoma 73120.

CONCORDIA KS
AUG 8

Hamfest — Cloud County Community College, Concordia, Kansas, August 8, 1976. Swimming, tennis, and radio-controlled model airplanes for the kids. Events for the XYLs. Prizes, meetings: 2 meter, ARRL, MARS, satellite. WØFNS Award, ham auction. Lew McCoy will speak at August 7 banquet.

FT. WASHINGTON STATE PARK PA
AUG 8

The Mt. Airy VHF Radio Club (the Packrats) are holding their annual family picnic in the Flourtown Area of the Fort Washington State Park on Sunday, August 8, 1976 (rain date 15 August). Talk-in via W3CCX/3 on 52.525, 146.52, and 222.98/224.58 MHz.

SAUK RAPIDS MN
AUG 8

The St. Cloud Radio Club Annual Hamfest will be held on Sunday, August 8, 1976, from 10 am till closing, at the Sauk Rapids Municipal Park. Free parking and overnight parking, hot dogs and pop available. Swapfest and ham gear sale. Talk-in on 34/94 and 3925. Hope to see you all there. For further info, contact Bill Zins WAØOTO, St. Cloud Radio Club, PO Box 752, St. Cloud MN 56301.

PETOSKEY MI
AUG 14

Straits Area Radio Club Swap and Shop will be held August 14 from 8 am to 4 pm at Emmet County Fairgrounds on US 31, ½ mile west of southern junction of US 31 and US 131, in Petoskey, Michigan. All amateurs, CBers, SWLs, $1 admission, 50¢ per table, door prizes, lunch counter, free parking. Talk-in on 3.920 MHz, channel 1, 146.52 MHz.

EAST RUTHERFORD NJ
AUG 14

The Knight Raiders VHF Club's auction and flea market will be held on Saturday, August 14th, at St. Joseph's Church of East Rutherford, Hoboken Road, East Rutherford. Free admission, free parking, refreshments available. Talk-in will be on 146.52. Doors will open 10 am. Flea market tables: $6 for a full table, $3.50 for half a table. Reserve your tables in advance by writing to The Knight Raiders VHF Club, K2DEL, PO Box 1054, Passaic NJ 07055.

HUNTSVILLE AL
AUG 15

The North Alabama Hamfest will be held on Sunday, August 15 at The Mall in Huntsville, Alabama. A hamfest supper will be held on Saturday night. Events include prize drawing, flea market, ARRL forum, MARS meetings, displays, and XYL programs. Talk-in on 146.94 and 3965. For more information contact N.A.H.A., PO Box 423, Huntsville AL 35804.

NEW CASTLE DE
AUG 15

Delmarva's new annual hamfest will be held August 15, 1976 at Wilmington College, New Castle, Delaware — U.S. Route 13 just north of Delaware Route 141 in New Castle, New Castle County. Tail-gating $2.50 per space. Rummage and display tables $5 per table. Food and camping available. Ladies' Bingo. Admission $1.75 advance — $2.50 at gate. Children are free. Make all checks payable to Delmarva Hamfest Inc. Mail all requests for reservations and information to John Low K3YHR, 11 Scottfield Drive, Newark DE 19713.

PUYALLUP WA
AUG 21-22

The Radio Club of Tacoma (W7DK) presents HAMFAIR-76, Saturday and Sunday, August 21st and 22nd, at the Pierce County Fairgrounds, 11 miles South of Puyallup Washington. This ARRL sanctioned event features technical seminars, women's and children's activities, contests, flea market, Saturday evening dinner and entertainment, Sunday morning loggers breakfast, and free camping with electrical hookups. First prize is an ICOM IC-230. Contact W7GPR, 3421 E. 138th St., Tacoma WA 98446, phone 531-3821.

SPRINGFIELD MO
AUG 22

The Southwest Missouri Amateur Radio Club will hold its annual hamfest, swap meet and family picnic on August 22, 1976, at Lake Springfield Park. This picnic attracts over two hundred radio amateurs and their families from southwest Missouri, northwest Arkansas, southeast Kansas, and northeast Oklahoma each year. For more information write: James A. Crooke, Secretary, Southwest Missouri Amateur Radio Club, 1601 South Kimbrough Avenue, Springfield MO 65807.

AURORA IL
AUG 22

The Fox River Radio League W9CEQ Hamfest will be held August 22, 1976 at beautiful Phillips Park, east edge of Aurora, U.S. Hwy. Rt.

Ham Help

Would appreciate plans for SIMPLE Novice band receiver.

C. E. Moore
1112 W. Tucker
Arlington TX 76013

Please place my name in your Ham Help column. I am willing to help people in the NYC-Long Island area get their licenses, or to help Novices upgrade.

David M. Krumholz WA2YYL
148-10 Huxley St.
Rosedale NY 11422

Since I first become a ham, I subscribed to *QST* first, then *Ham Radio*. Both left a lot to be desired. *QST* is the better of the two, however; *Ham Radio* was just plain over my head. Then a friend and fellow ham straightened me out and I subscribed to *73*. At first glance I knew I had found the right mag for me. I must say some of the best and most interesting material is found in your editorials and letters from other hams. If you'd like you can use this one for a sales pitch. Also, please enter my name into your "Ham Help" column for anyone who needs help. I started a ham club here in Hoosick Falls and have gotten 5 guys their Novices. Three new members are about ready for theirs. That is why I am sending for code tapes. Six of us are boning up for our General tests. Also, I would like to add my coupon to extend my subscription for three years. Keep up the good work for your fellow hams.

Dave Kessler WN2SSR
Hoosick Falls NY

Please add my name to your list of helpers. I'd be glad to lend assistance to any aspiring hams-to-be in the Pittsburgh vicinity.

I am not an amateur radio operator at this moment, but I really want to become one. I get a copy of *73* monthly at the newsstand. I love reading it. Could you please list me in your "Ham Help" column? Thank you very much.

In your person I should like to ask your outstanding magazine to give me help. I would like to get in touch with a ham whose profession is linguistics — more concretely, applied linguistics, terminology, linguostatistics. My ex-call was UA6LMX; my new call has not been received yet. Languages are English and Russian. I'm sorry for the trouble I'm giving you.

Serge P. Kushneruk
Box 34, GPO, Tyumen
USSR

First, to the Ham Help column — Help!!! I'm a CBer, KNK2337, who has been interested in amateur radio for almost sixteen years but never had the free time necessary for more than superficial learning. I've also been studying electronics by home study for three months, so I'm not a complete ignoramus about electronics, just close. Am very interested in FM, SSB and 2 meter operations. I'd greatly appreciate help in making the transition.

Do you guys personally know of any ham shops in the area? CB seems to be all over the place, but the only other radios I've seen so far are scanning monitors. I've gotten three issues of your magazine now and I think it's great. I am interested in computers and think you should keep those articles in. I may understand in general only every fourth word, but it's a joy to struggle for the rest. Thanks for your help.

Gregory W. Lincavage
23 Kingsland St.
Nutley NJ 07110

I would like to know if anyone can obtain a matching speaker for an Allied AX-190 receiver. I would be very interested in purchasing this.

Mike Evans
Box 985
Ft. Smith AR 72901

#30. All day family fun, picnic, zoo, lake and flowers. Same old price — $1.00 advanced with SASE to FRRL, PO Box 443 Aurora IL 60507. Talk-in on 146.94.

RENO NV
AUG 28

Nevada Amateur Radio Association will again host the Sierra Nevada Hamfest, August 28, 1976, at the California Building, Idlewild Park, Reno, Nevada. Pre-registration $10, until August 21. For further details, write P.O. Box 2534, Reno, Nevada 89505.

ATLANTIC CITY NJ
AUG 28-29

The Personal Computing '76 Consumer Trade Fair will be held August 28-29, 1976 in Atlantic City, New Jersey. Seminars and technical talks, major exhibits, demonstrations, door prizes, and free literature all about software and hardware development, microcomputers, memories, comparisons, interfacing, implementation, AMSAT, computerized music, video terminals, construction, printers, games, and tapes. Admission $5 advanced, $7.50 at door (includes exhibits and seminars). Exhibition booths — call (609) 927-6950.

LA PORTE IN
AUG 29

The combined La Porte County Amateur Radio Clubs will hold their Fall Hamfest on Sunday, August 29th, 1976 at the La Porte County Fairgrounds in La Porte, beginning at 7 am Chicago time. Overnight camping available. Indoors in case of rain. No table or set-up charge. Paved midway, good food and drink. $2 donation at the gate. For more information write: PO Box 30, La Porte IN 46350. Talk-in on 01-61 and 94 simplex.

SO DARTMOUTH MA
AUG 29

The Southeastern Amateur Radio Club is having a Flea Market and Picnic on August 29, 1976 at the Stackhouse Fairgrounds in So. Dartmouth MA. Space will be $2 and table an additional $2. Homemade food, magic show for the children, and many raffles. For a flier write: Arthur Sylvia, 317 Nemasket St., New Bedford MA 02740.

EL PASO TX
SEPT 4-5

The ARRL Hamfest will be held eptember 4-5 at the elegant Vista Motor Inn. Seminars, solar power, xotic modes, OSCAR and fleaarket. Write PO Box 24050, El Paso X 79914. Visit us on Labor Day weekend!

MENA AR
SEPT 4-5

The Queen Wilhelmina Hamfest 1976 is Saturday and Sunday, eptember 4 and 5, at Queen Wilhelmina State Park, Rich Mountain, Mena, Arkansas. Excellent accommodations and food at the newly restored historic Queen Wilhelmina Castle. Door prizes hourly, grand prize, new equipment displays, flea market, camping area with utilities and rest rooms, amusements for harmonics. Talk-in 146.52. For more information write WB5CXX, P.O. Box 5191, Texarkana TX or phone (214) 838-0625.

DANVILLE IL
SEPT 5

The Danville Hamfest will be held at Douglas Park, Danville, Illinois September 5. Downstate Illinois' largest. Great prizes. Advance tickets $1.75 ea., 3/$5 with an SASE to Jim Wilson, 308 First, Ridgefarm IL 61870. Talk-in 22/82 and 3910.

YORK PA
SEPT 5

The 21st Annual York County Hamfest will be held September 5th, rain or shine, 10 miles west of York PA; ½ mile west of York Airport, turn south off Rt 30 to Elickers Grove. Registration begins at 9 am — fee $3.00. All adults and amateurs are expected to register, XYLs and children free. A limited number of flea market tables are available inside by advance reservations *only*. Contact hamfest committee. There will be a $5.00 charge for using electric power. Talk-in 146.04-64; 28-88; 52-52. For more information write or phone Leroy Frey K3POR, 170 S. Albemarle St., York PA 17402, phone 854-1203.

BEREA OH
SEPT 11

The '76 Cleveland Hamfest presented by the Cleveland Hamfest Association will be held Saturday, September 11 at 8 am to 6 pm at the Cuyahoga County Fairgrounds, Berea, Ohio. Eastland Road entrance only to County Fairgrounds with easy access from Hopkins Airport, Interstate I-71, I-90 or Ohio Turnpike. Tickets $1.50 before August 31; $2.00 at 0800 for all 12 or over when gates open. Asphalt quad flea market parking $1 additional per space at 0700. Bring your own tables and shade. Registration: $1.50 tickets by mail before August 31 with check or money order to: Cleveland Hamfest Association, P.O. Box 43413, Cleveland, Ohio 44143.

MELBOURNE FL
SEPT 11-12

The 11th annual Melbourne, Florida hamfest will be held Saturday and Sunday, September 11-12, 1976, from 9 am to 5 pm each day in the air-conditioned Melbourne Civic Auditorium located on Hibiscus Boulevard. Donation is $2.50 per adult. Full program includes forums, meetings, auction, swap tables, commercial exhibits, awards, prizes, etc. Talk-in on 25/85 and 52/52. Sponsored by Platinum Coast Amateur Radio Society. For more info write PO Box 1004, Melbourne FL 32901. FCC exams in Ramada Inn Saturday at 8 am for General, Advanced, and Extra. Form 610 and $4 fee must be filed with FCC, Room 919, 51 S.W. First Avenue, Miami, no later than August 31, 1976.

FINDLAY OH
SEPT 12

The 34th Annual Findlay Hamfest will be held on Sept. 12 at Riverside Park, Findlay, Ohio. Talk-in 146.52. For advanced tickets and/or info write: Clark Foltz W8UN, 122 W. Hobart St., Findlay, Ohio 45840 (SASE please for under 5 tickets).

MALAGA NJ
SEPT 12

The South Jersey Radio Assn. 28th Annual Hamfest will be held September 12, 1976, 10 to 5 pm, at Molia Farms, Malaga, New Jersey. Lake, picnic grounds and food available. Tailgate sales, swap shop and door prices. Family tickets: advance sales — $2.50, gate sales — $3.50. Advance sales send SASE to Jack Koch, Box 103, Cherry Hill NJ 08002. Talk-in 146.52.

HAMBURG NY
SEPT 18

The Hamburg International Hamfest will be held September 18, 1976 at the Erie County Fairgrounds in Hamburg, New York. Directions: Take the New York State Thruway to the Blasdell Exit (Exit 56). Recreational vehicles will turn right on Mile Strip Road and turn left on Route 62 South (first major intersection). Follow the signs to the Erie County Fairgrounds entrance. All other vehicles turn left on Mile Strip Road and turn right on McKinley Parkway (first major intersection). Hamfest will include giant flea market, technical forums, picnic facilities, excellent programs, non-amateur displays, code contest, women's programs, organization meetings, equipment displays and FM hospitality room, and thousands of dollars in awards. Admission: $3 at gate, $2.50 in advance. $1 for flea market parking. Children under 12 admitted free. Talk-in stations will be on the WR2ABU repeater (146.31 in, 146.91 out), 146.52 simplex, 7.255 (ECARS), and 3.925. For more information contact Bert Jones W2CUU, 143 Orchard Drive, Kenmore NY 14223, tel. 716-873-3984.

NEW KENSINGTON PA
SEPT 19

The Skyview Radio Society's Swap & Shop will be held on Sept. 19, 1976 at the Skyview Radio Club, New Kensington PA. Registration $1. Talk-in 52-52 and 04-64.

NEW BERLIN IL
SEPT 26

The Sangamon Valley Radio Club Hamfest will be held September 26 at the Sangamon County Fairgrounds, New Berlin, Illinois, twelve miles west of Springfield (Illinois state capitol) on Route 36. There will be food, programs, covered pavilion, and nearby camping. See Lincoln shrines. Talk-in 28/88 AF9AFA. Tickets $1.00. Write: K9HDZ, 622 Magnolia, Rochester, Illinois.

FIRST REPORT AND ORDER
Adopted: June 9, 1976;
Released: June 15, 1976

By the Commission:

1. On December 16, 1974, the Commission released a Notice of Proposed Rule Making in this proceeding which was published in the Federal Register on December 20, 1975 (39-FR44042). Comments were due by June 16, 1975, and reply comments by July 16, 1975. The due dates for both comments and reply comments were extended, and the final cutoff dates were set at July 16, 1975, and September 1, 1975, respectively.

2. The purpose of the Notice was to consolidate into one rulemaking proceeding the many petitions we had received which dealt one way or another with changing the structure of the Amateur Radio Service. We recognized that the requests found in the petitions were often interrelated, and should not be handled on a piecemeal basis. For this reason, we undertook a fundamental review of the entire structure of the Amateur service and proposed various changes in that structure.

3. The major proposed rule changes contained in the Notice were the following:

a) Creation of a "dual ladder" licensing structure;

b) Creation of a Communicator Class license having no telegraphy privileges or examination requirement;

c) Establishment of new power limits based on transmitter peak envelope power output;

d) New restrictions on licenses obtained by means of volunteer-administered mail examinations;

e) Issuance of lifetime Amateur Extra Class operator licenses; and

f) Modification of the frequencies and modes available to certain license classes.

4. An estimated 4000 comments and reply comments were filed in this Docket. They ranged from postcards to multipage typewritten statements, often with very detailed analyses of our proposals coupled with suggested revisions thereto. All of these comments have been read and carefully considered. Also, in addition to these documents, we have closely examined the results of a poll taken by the American Radio Relay League (ARRL) which elicited responses from many thousands of that organization's members.

5. Because of severe manpower and time restrictions brought about by the recent surge in Citizens Radio Service applications, we are unable at this time to undertake the preparation of a comprehensive Report and Order which would address all of the issues raised in the Notice. We are therefore releasing this First Report and Order in which several matters of importance will be addressed, and we plan to prepare additional Reports and Orders in the future as our workload permits.

6. Firstly, we will address the matter of examinations administered by volunteer examiners. Under the system put forth in the Notice, all licenses obtained in this way, except Novice licenses and licenses granted in those instances where the applicant qualified for a volunteer-administered examination on the basis of a protracted disability which prevented travel to a Commission examination point, were to be non-renewable. Such licenses were to be temporary, and the licensees would have been required to successfully complete a regular Commission-supervised examination in order to remain licensed. This arrangement would have required all presently licensed Technician (C) and Conditional licensees to undergo reexamination by the Commission. Failure to successfully complete the Commission-supervised examination would have

meant that the licensee could not have continued to renew his license upon expiration.

7. As one of the broad objectives in this proceeding, we stated in the Notice that we desired to preclude, or at least minimize, any adverse impact upon presently licensed amateurs. The sentiments in the comments overwhelmingly supported this posture, and we continue to believe it to be the only reasonable course of action. Many comments objected to our "non-renewability" proposal for volunteer-administered examinations as being detrimental to amateur radio in general and excessively burdensome to thousands of licensees who, for valid reasons, did not undertake Commission-supervised examinations. Moreover, inasmuch as the Technician Class license program has always been, by Commission intent, based primarily on volunteer-administered examinations, a mass recall of these persons does not now appear equitable. We are in basic agreement with these objections, and have modified our proposal to blunt any ill effects on present licensees. We believe the limited resources available to us can be best utilized elsewhere.

8. However, our experience with the volunteer examination program has shown that it has been abused. Our routine call-in program of Technician(C) and Conditional Class licensees has shown that over 90% of such persons either fail to appear for re-examination, or if they do appear, fail the examination. Such results tend to confirm the suspicion that some such licensees obtained their licenses fraudulently. We have therefore determined to limit the availability of volunteer-administered examinations to the following categories of applicants:

a) Applicants for the Novice license; and

b) Applicants who show by physician's certification that they are unable to appear at a Commission examination point because of a protracted disability preventing travel.

All applications for mail examinations on the basis of a protracted disability should now be sent to the FCC field office nearest the applicant, rather than to the Commission's offices in Gettysburg, Pennsylvania. Such examinations will be conducted by a volunteer examiner selected by the Commission, or by Commission personnel.

9. Persons now holding licenses obtained on the basis of a mail examination will not be adversely affected by this rule change. All such licenses may continue to be renewed, and Rule Section 97.25 is being modified to indicate that examination credit will be given for those elements which were passed without Commission supervision. For instance, a Technician(C) licensee will automatically be given credit for Element 3 should he attempt to obtain a General Class license. He would be required only to pass Element 1(B), the 13 wpm telegraphy test. We believe that this "grandfather" provision penalizes no one, and will encourage such licensees to upgrade. Upon application for license modification or renewal, all present Conditional Class licensees will be issued General Class licenses, and all Technician(C) licensees will be issued Technician licenses. Henceforth, all applicants passing Elements 1(B) and 3 on a volunteer-administered examination will be issued a General Class license. The Conditional Class will no longer be issued.

10. The elimination of the 175 mile distance eligibility criteria for the Conditional Class (now General Class) license will not, in our view, impose an undue hardship on those persons sincerely interested in obtaining an amateur license. The number of such applications received is now slight, and the enlargement of the Commission's examination schedule for remote points all but eliminates the usefulness of the 175 mile criterion. With respect to the Technician(C) Class license, we do not foresee any significant adverse impact resulting from its elimination. The vast majority of persons seeking that license live within convenient travel distance of a Commission examination point, and our examination policy with respect to the Technician Class is now consistent with our policy governing all license classes except Novice. As proposed, we are also deleting the availability of mail examinations on the basis of eligibility criteria set out in §97.27(c) and (d).

11. A related issue we will address at this time involves the Novice Class license. Many thousands of Novice examinations are given each year, and this has been the gateway to Amateur radio for over half of all present licensees. We believe the experience of taking the Novice test to be very worthwhile, inasmuch as there is no overlap in the Novice examination questions and the questions found on more advanced examinations. We are therefore amending the Rules to require that all persons entering Amateur Radio Service, at any level, successfully complete examination element in addition to the other examination elements presently required for the license examination being undertaken. We are also at this time deleting the provision in Section 97.9(f) which prohibits the issuance of a Novice Class license to a person who has held within the prior 12 month period any class of Amateur radio license. We believe this provision serves no useful purpose and has prohibited otherwise qualified persons from remaining in Amateur radio.

12. The final matter we will touch on in this First Report and Order involves the privileges available to Technician and Novice Class licensees. Until several years ago, it was permissible for a licensee to hold both the Novice and Technician Classes of license at the same time. Such dual licensing was

subsequently prohibited in Section 97.9(f), which states that the Novice Class license may not be concurrently held with any other class of license. We have received several petitions to lift this restriction, and in our Notice we proposed to include Novice Class privileges in the Technician Class license. We are herein adopting that proposal, which was widely supported in the comments. We are also modifying the maximum permissible transmitter power input which Novices, and all other license classes, may utilize when operating on Novice frequencies. We are limiting to 250 Watts the maximum power input which may be used by any class of operator transmitting in Novice sub-bands. We are adopting this change for two reasons; firstly, it will mean that a Novice can buy equipment which will be readily useable and practical when he upgrades to General Class and above. Presently, in order to conform to the 75 Watt power limit, Novices oftentimes are forced to buy low power transmitters which they find have limited usefulness outside Novice sub-bands; and secondly, we see no reason to permit non-Novices to utilize high power in a sub-band where such power gives them a significant advantage over a license class which is restricted to that sub-band.

13. In view of the foregoing, we are of the opinion that the amended rules as discussed above are in the public interest, convenience, and necessity. Accordingly, pursuant to authority contained in Section 4(i) and 303 of the Communications Act of 1934, as amended, IT IS ORDERED, that Part 97 of the Commission's Rules IS AMENDED as set forth in the Appendix attached hereto. These amendments become effective July 23, 1976.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

APPENDIX

Chapter 1, Part 97 of Title 47 of the Code of Federal Regulations is amended as follows:

1. In Section 97.7, paragraphs (b), (c) and (d) are amended and (e) is added to read as follows:

§97.7 *Privileges of operator licenses.*

* * * * *

(b) *General Class.* All authorized amateur privileges except those exclusive operating privileges which are reserved to the Advanced Class and/or Amateur Extra Class.

(c) *Conditional Class.* Same privileges as General Class. New Conditional Class licenses will not be issued. Present Conditional Class licensees will be issued General Class licenses at time of renewal or modification.

(d) *Technician Class.* All authorized amateur privileges on the frequencies 50.1-54 MHz and 145-148 MHz and in the Amateur bands above 220 MHz. Such licenses also carry the full privileges of the *Novice Class* license.

(e) *Novice Class.* Radiotelegraphy in the frequency bands 3700-3750 kHz, 7100-7150 kHz (7050-7075 kHz when the terrestrial station location is not within Region 2), 21,100-21,200 kHz, and 28,100-28,200 kHz, using only Type A1 emission.

2. Section 97.9 is amended to read as follows:

§97.9 *Eligibility for new operator license.*
Anyone except a representative of a foreign government is eligible for an amateur operator license.

3. Section 97.11(b) is amended to read as follows:

§97.11 *Application for operator license.*

* * * * *

(b) An application (FCC Form 610) for a new operator license, including an application for change in operating privileges, which requests an examination supervised by a volunteer examiner under the provisions of §97.27, shall be submitted to the FCC field office nearest the applicant. Applications for the Novice Class license should be sent to the Commission's offices in Gettysburg, PA 17325. All applications should be accompanied by any necessary filing fee.

* * * * *

4. Section 97.23 is amended to read as follows:

§97.23 *Examination requirements.*
Applicants for operator licenses will be required to pass the following examination elements:

(a) Amateur Extra Class: Elements 1(C), 2, 3, 4(A) and 4(B);

(b) Advanced Class: Elements 1(B), 2, 3, and 4(A);

(c) General Class: Elements 1(B), 2, and 3;

(d) Technician Class: Elements 1(A), 2, and 3;

(e) Novice Class: Elements 1(A) and 2.

5. Section 97.25(a) is amended to read as follows:

§97.25 *Examination credit.*

(a) An applicant for a higher class of amateur operator license who holds any valid amateur license will be required to pass only those elements of the higher class examination that are not included in the examination for the amateur license held.

* * * * *

6. Section 97.27 is retitled and amended to read as follows:

§97.27 *Mail examinations for applicants unable to travel.*
The Commission may permit the examinations for an Amateur Extra, Advanced, General, or Technician Class license to be administered at a location other than a Commission examination point by an examiner chosen by the Commission when it is shown by physician's certification that the applicant is unable to appear at a regular

Commission examination point because of a protracted disability preventing travel.

7. Section 97.28 is retitled and amended to read as follows:

§97.28 *Manner of conducting examinations.*

(a) Except as provided by §97.27, all examinations for Amateur, Extra, Advanced, General, and Technician Class operator licenses will be conducted by authorized Commission personnel or representatives at locations and times specified by the Commission. Examination elements given under the provisions of §97.27 will be administered by an examiner selected by the Commission. All applications for consideration of eligibility under §97.27 should be filed on FCC Form 610, and should be sent to the FCC field office nearest the applicant. (A list of these offices appears in §0.121 of the Commission's Rules and can be obtained from the Regional Services Division, Field Operations Bureau, FCC, Washington, D.C 20554, or any field office.)

(b) Unless otherwise prescribed by the Commission, examinations for the Novice Class license will be conducted and supervised by a volunteer examiner selected by the applicant. The volunteer examiner shall be at least 21 years of age, shall be unrelated to the applicant, and shall be the holder of an Amateur Extra, Advanced, or General Class operator license. The written portion of the Novice examination, Element 2, shall be obtained, administered, and submitted in accordance with the following procedure:

(1) Within 10 days after successfully completing telegraphy examination element 1(A), an applicant shall submit an application (FCC Form 610) to the Commission's office in Gettysburg, Pennsylvania 17326. The application shall include a written request from the volunteer examiner for the examination papers for Element 2. The examiner's written request shall include (i) the names and permanent addresses of the examiner and the applicant, (ii) a description of the examiner's qualifications to administer the examination, (iii) the examiner's statement that the applicant has passed telegraphy element 1(A) under his supervision within the 10 days prior to submission of the request, and (iv) the examiner's written signature. Examination papers will be forwarded only to the volunteer examiner.

(2) The volunteer examiner shall be responsible for the proper conduct and necessary supervision of the examination. Administration of the examination shall be in accordance with the instructions included with the examination papers.

(3) The examination papers, either completed or unopened in the event the examination is not taken, shall be returned by the volunteer examiner to the Commission's offices in Gettysburg, Pa., no later than 30 days after the date the papers are mailed by the Commission (the date of mailing is normally stamped by the Commission on the outside of the examination envelope).

(c) The code test required of an applicant for an amateur radio operator license, in accordance with the provisions of §§97.21 and 97.23 shall determine the applicant's ability to transmit by hand key (straight key or, if supplied by the applicant, any other type of hand operated key such as a semi-automatic or electronic key, but not a keyboard keyer) and to receive by ear, in plain language, messages in the International Morse Code at not less than the prescribed speed during a five minute test period. Each five characters shall be counted as one word. Each punctuation mark and numeral shall be counted as two characters.

(d) All written portions of the examinations for amateur operator privileges shall be completed by the applicant in legible handwriting or hand printing. Whenever the applicant's signature is required, his normal signature shall be used. Applicants unable to comply with these requirements, because of physical disability, may dictate their answers to the examination questions and the receiving code test. If the examination or any part thereof is dictated, the examiner shall certify the nature of the applicant's disability and the name and address of the person(s) taking and transcribing the applicant's dictation.

8. Section 97.29 is deleted and redesignated as reserved.

9. Section 97.31(a) is amended to read as follows:

§97.31 *Grading of examinations.*

(a) Code tests for sending and receiving are graded separately.

* * * * *

10. Section 97.33 is amended to read as follows:

§97.33 *Eligibility for re-examination.*

An applicant who fails a written examination for an amateur radio operator license may not take another written examination for the same or higher class license within 30 days.

11. Section 97.35 is deleted.

12. In Section 97.67 paragraph (a) is amended and (d) is added to read as follows:

§97.67 *Maximum authorized power.*

(a) Except for power restrictions as set forth in §97.61 and paragraph (d) below each amateur transmitter may be operated with a power input not exceeding one kilowatt to the plate circuit of the final amplifier stage of an amplifier oscillator transmitter or to the plate circuit of an oscillator transmitter. An amateur transmitter operating with a power input exceeding 900 Watts to the plate circuit shall provide means for accurately measuring the plate power input to the vacuum tube or tubes supplying power to the antenna.

* * * * *

(d) In the frequency bands 3700-3750 kHz, 7100-7150 kHz (7050-7075 kHz when the terrestrial location of the station is not within Region 2) 21,100-21,200 kHz, and 28,100-28,200 kHz, the maximum plate input power which may be utilized is 250 Watts.

Tracking the Hamburglar

ABDUCTED: Drake ML2 no. 11512. Xtals for 10 channels, green sub min. coax connected for T/T pad to coax conn BNC on rear, 1 coax sub min. connected to dev. terminals. Stolen March 26, 1976 in Andover, Massachusetts. Contact Frank S. Minas WA1MJI, 16 Cottage Street, Exeter NH 03833.

LIFTED: Genave GTX-1T handheld transceiver, s/n 13-07 stolen from our booth at the Dayton Hamfest. Contact Claude L. Henderson, Vice President, General Aviation Electronics, 4141 Kingman Drive, Indianapolis IN 46226, phone (317)-546-1111.

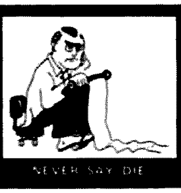
GONZO: Icom IC-230 2m FM transceiver, s/n 2406312, with all 5 West Coast split-split crystals. Inscribed on rear chassis: "CA DL #G516583" and "K6ICS". Contact Dr. Michael K. Gauthier, 9550 Gallatin Road, Downey CA 90240, (213)-923-0131.

RUSTLED: Icom IC230 two meter fm transceiver with mount and 82 xtal, s/n 2835. TPL Model 1002 two meter power amplifier, s/n 0426. Regency 10 channel scanner model ACTR 10HLU with all crystals and antenna junction box, s/n 185A88279. Stolen from the Mission Valley area of San Diego on May 17, 1976. If located, advise San Diego Police Dept, Burglary Div. at 236-6281 (case #76-33350), or contact Zane Sprague K6WK (714) 481-0594.

TAKEN: Unimetrics Ultra-Com 25, s/n 080213, stolen from locked auto parked in residence driveway, about 5 am, May 12, 1976. Unit enscribed in two places with N.C. driver's license number, 2067134. Contact Greensboro N.C. Police Dept., or W4DWR.

STOLEN: GTX-2 s/n 29-63 and ID no. 020-34-2737. GLH-100 and same ID no. Taken from my car on June 12, 1976. I am offering $100 for the recovery and conviction of the persons responsible for the theft. Paul F. Kelley K1UXD, 165 Garfield Avenue, Hyde Park MA 02136.

REMOVED: Icom IC-22A transceiver, s/n 1216, 16/76, 31/91, 01/61 xtals also in radio besides standard xtals from Icom. The radio also had a Motorola type microphone, instead of the standard Icom mike. Realistic PRO-11 Scanner, s/n 08370930, xtals for 155.79 and 155.685 MHz. Sanyo FT-867 AM/FM/8 trk in dash car radio, s/n 87661611. Realistic MPA-10 PA amplifier, manufacturer did not put s/n on unit, also non-stock microphone with it. These items were stolen from my auto parked outside my home on the night of August 21, 1975. I also had my name and SSN (214-68-9618) engraved on each unit. Please contact Stephen E. Martin WA3SAD, 12115 Northwood Drive, Upper Marlboro MD 20870 or at this phone number: 301-627-4933, or contact the Prince Georges County Police, Bowie, MD, case number 75-233-163.



NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

from page 6

techniques and modes . . . who are on Oscar . . . the moonbounce groups . . . there are a whole lot of heros in amateur radio and I take my hat off to them.

If we must for some reason have limits on bandwidth, I don't think they should be written to kill off those old buggers on AM or the television pioneers on 420 MHz . . . they should be written to encourage amateur development and pioneering. Do you agree?

If we are going to let the door open for new RTTY and RTTY/computer communications systems, we need to set things up with plenty of latitude for experimentation.

In docket 20777 the proposal was for 350 Hz bandwidth for the CW parts of the band. This would force all of the special modes such as RTTY, high speed CW, and FAX to be in the phone bands. Is this what we want to do?

Are we so jammed up on our bands that we have to set the phone band bandwidths at 3500 Hz? This would eliminate any experimenting with new systems which might allow for greater savings in terms of bandwidth/time. It would prohibit work with a synchronous detecting system of communications. It would prohibit work with double sideband systems where picture info is on one sideband and voice on the other.

Yes, there are times when every Hz of band is needed . . . Saturday and Sunday afternoons can be difficult. There are also many hours when even the most crowded of bands are virtually empty. Should we set the rules to meet the problems of Saturday afternoon and forget about the other times? Should we have our rules so they are designed to limit us for our own sake during the peak of the sunspot cycles . . . or should we ask for rules which allow us to work within the limitations of the bands in which we are working? A chap with a 25 kHz wide signal on 10m these days is not much of a problem to anyone . . . so why make a rule to stop him? It just might be that this idiot is working on a super narrow band television system.

The use of the bands is self-limiting. As they become more crowded, wider band signals will have to wait. This is something that sort of takes care of itself. We don't need stifling rules to force us to do these things.

Okay . . . again let us suppose that the FCC takes the lid off and says go ahead and use any width signals you want on any frequencies you want. What may happen? I suspect that without guidelines we would be in a pickle. Anarchy is not good either. Perhaps the FCC could say that we would no longer be bound by FCC regulations on bandwidths and subbands, but that they recommend we keep our present system until we are able to come up with a plan that we agree is better.

DUMP BANDWIDTH

I'm hoping you'll agree with me and write to the FCC asking that they not put through docket 20777. I'm hoping you'll ask them to get rid of limitations to experimenting and modes . . . even sub-bands. Oh, I guess we'd better keep the Novice bands, since the FCC is about to virtually throw them open to anyone who wants to give hamming a try.

Send your comments to the FCC, Washington DC 20554, and mention 20777. If you have a copier send the 15 copies . . . if not, send at least one . . . but *send.*

CONDITIONAL LICENSES DELETED

Johnny Johnston announced at Atlanta that on July 23rd the Conditional Class of license would be eliminated. Conditional Techs would be grandfathered into the regular Tech license and all other Conditionals would be grandfathered into the regular class of license.

Johnny admitted that only about 10% of the Conditionals called up are able to pass their test, but the prospect of trying to re-examine over 82,000 Conditionals was not pleasant. The FCC is just barely getting out of the mess caused by the flood of CB licenses and one thing they don't need is another big hassle.

To give an idea of what the Commission was up against with the CB licenses, Johnny showed some slides of their Gettysburg facility. About a year ago they would get one thin mailbag of license applications a day for all the services they handled. This has increased a bit and now runs over 80 mailbags a day on busy Mondays. They've been able to get permission to add a few temporary employees to help, but the whole thing is a madhouse.

To me this change means that all of us have to accept that we are now on equal terms with some chaps who have paid $100 for a General license or $10 for a Tech license and who don't even know the code. Okay, we have absolutely nothing to gain by bitching about it or making these chaps uncomfortable . . . they have enough of a problem living with their cheating, without our rubbing their noses in it. What we have to do is make sure that our clubs have darned good technical sessions and code classes so everyone in the hobby will learn and have more fun with amateur radio. The more you know about hamming, the more fun it is.

There is no indication that the code is going to be relaxed for the General Class and above tickets, so we can certainly do all we can to get every ham to pass the 13 wpm exam. It is now recognized that probably the worst possible way to try to get code speed is to start slow and gradually try and build up speed . . . say on the air. Johnny mentioned that this never worked for him either and that he got his code speed up by using tapes.

The *73* tape is only $3.95, so it isn't a big deal and can be used whenever the time permits. But it is more fun to get together with the club and have a short code copying session . . . probably about 20 minutes is right . . . as part of each meeting. It is vitally important to remember to keep code fun. As soon as you find yourself getting bored or fidgety, do something else. Keep the pressure off . . . take it easy . . . and have fun copying.

I'll try to get as many articles for *73* as I can which will help newcomers get the hang of radio theory. Authors please take note. If you've any experience in teaching at clubs, you'll reach a lot more people via articles in *73* . . . and the prestige of being published may make your audience listen a little more carefully.

My petition to permit Techs to use the Novice bands was part of this docket on the Conditional licenses. It is about time! And they made one other *big* change . . . Novices will be able to use 250 Watts input instead of 75. The reasoning was that Novices need to have good equipment to operate in their crowded bands, and this means buying a regular ham transceiver. Most of these have sweep tube finals and run in the 150-250 Watt range. So why not make that the power limit? And just to make it a bit more fair, *any* operator using the Novice band must keep his power to the 250 Watt limit.

COMMUNICATOR LICENSES

The FCC is still thinking seriously about the Communicator license, and they are now talking in terms of perhaps millions of them. They are not about to open this can of worms until they have a lot of other parts of their act going . . . like being able to handle the license applications.

The FCC is all tied up with problems on opening new channels for CB. There is a general agreement that CB needs more channels. I'm not convinced of this yet. I'd like to see a study of channel use. I think it would refute the more channel idea. They were just about to okay the channel increase when tests showed that two CBers 450 kHz apart in channels generated a good deal of intermod on the i-f and raised miseries on all channels of sets within several miles! Further tests indicated that signals on half the i-f frequency were also generating substantial intermod and that this might be responsible for quite a bit of the interference many CBers were getting. The FCC found that some CB sets were particularly dirty and it is certain that the Commission will be reviewing their type acceptance of several sets.

The FCC is well aware of the problems that sunspots and increased skip are going to make for them. The impact is going to be really serious when about seven million CBers discover that 23 over-powered stations in the midwest can wipe out much of the country. This means that the FCC has to get something going on a higher frequency band pretty soon. With the licensing mess they've had little time to do much else . . . except sweat. They know what is going to happen and they are so understaffed they are almost powerless to cope.

The Communicator license could be one thing to help get them off the spot. They can answer millions of screaming furious CBers with a simple ham ticket which will allow them to keep hamming away . . . on a band without skip . . . and legally. No code, darned little other exam . . . perhaps a short course with a local ham club which then can hand out the license.

I just wanted you to see what is happening and why. If you have any better ideas on what to do, let the FCC know . . . and me. The FCC hasn't time or people to read your letter, and neither do I . . . but I'll try . . . and they may too. Hey! Why not write to the ARRL . . . *they* have the time.

NO FUELING

Put on your blue sky thinking cap with me for a moment.

There has been a lot of PR given to a need for saving fuel. I don't think any of us really disagree with the fact that there is a problem . . . it's just that few of us are willing to voluntarily make big sacrifices in the name of fuel saving without some evidence that everyone else is hurting, too.

Now what do we spend a lot of gas on that could be saved? Well, I don't know about you, but trips to stores put a lot of mileage on my car. There are three or four trips to the supermarket a week, a couple to the hardware store, one or two to a department or discount store . . . several to the book/stationery store . . . things like that.

Add to my trips those of deliveries to my home . . . cleaning, UPS, mail . . . things like that.

Suppose some firm . . . perhaps UPS . . . got involved with a super delivery service which would bring mail, groceries, cleaning, hardware, Sears stuff, and everything else all at one time? Right there we could save over 50 million gallons of gasoline a day. Let's suppose that the delivery trucks, since they wouldn't have very far to drive, could be battery-powered . . . charged up overnight. Think of the pollution that would be eliminated . . . how much longer cars

would last without these unending short trips to the store . . . how much would be saved on insurance by keeping cars out of parking lot accidents.

Older folk will remember the time when most grocery shopping was done by telephone and the grocer delivered. Supermarkets killed this nice way of doing things . . . substituting a whole lot of your time in exchange for that of the delivery boy and the grocery clerk . . . plus your gas. Remember that most delivery boys used bicycles.

We can go back to the phone again . . . perhaps this time by way of the microcomputer which will give us pricing and buying information on all products and permit us to order them and pay at the same time via something like Master Charge.

Perhaps the time will come when most of our stuff will come by way of a daily (or twice daily) van . . . groceries, cleaning, mail, packages, drugs, Sears, hardware, liquor . . . ? The plan would seem to have enough economies in it to make it worthwhile to set up. And it would help in the energy crunch . . . and pollution problem . . . if the non-use of about 435 million barrels of gas a year is of any importance.

Until such time as small computers are in widespread use, it is unlikely that any serious computer-to-computer via phone lines system can be set up to get around our deteriorating and increasingly costly mail "service." But the one thing the post office has that has kept them in business despite their problems and cost has been a delivery service that reaches everywhere.

Suppose that my suggested delivery service were to get going . . . and were to catch on widely. It might be that it could be used by a "Western Union" type of outfit to deliver messages. On the other hand, with all those microcomputers out there for ordering merchandise and groceries . . . it might be that electronic mail would develop. Either way, such a system could serve that additional benefit . . . a fast and inexpensive mail service.

CBers

A letter from J. Henry Felton, who lists his calls as AA4HXZ-WR4AKX, says, "Wayne, what is that I see on page 46 of the July *73*? Bad news! Is *73* going 'CB'? If it takes ads like that to get 176 pages, then cut down to 120 pages. *73* has been the best since day one, you don't need CB ads. Let *CQ* have them!"

I expected a bit of flack on the CB ad, but really I expected a bit more than one letter . . . thanks J. Henry, for writing and giving me a chance to say something.

No, *73* is not going "CB." And while I would accept ads from Fredericks of Hollywood or Idaho potatoes to help pay for more space to print articles . . . every additional page of ads makes it possible to print about two or three pages of articles . . . I still won't permit ads from ham manufacturers selling bum products or providing lousy service. Not that CB ads are all that far out anyway.

If you have been reading my editorials for very long, you are quite aware that as situations change, my opinions change with them. I try to keep up to date and get all the input I can. A case in point is CB. A couple years ago you found me pretty sarcastic and negative about CB. I think that was appropriate at the time. Since then the situation has changed.

Two things happened. One was the sunspot minimum, which allowed 11m to settle down to a local band for a few years. The second was the national 55 mph speed limit. This combo got the truckers into CB and that got CB into the newspapers . . . and that got CB into the cars of several million people. Note that the CBers of today are rarely the CBers of two or five years ago. In most areas of the country bad language is a rare exception.

A great many amateurs are putting CB rigs in their cars and every one I've talked with is very enthusiastic about it. During my talk at Atlanta I asked for a show of hands of amateurs who were also using CB. Over a hundred hands went up. I then asked how many of them would be without it . . . only one hand went up. I know I wouldn't be without it. When I fly anywhere I take along both a ham rig for the repeaters and a CB rig for road information.

If you run up against a seriously anti-CB amateur, ask him the same question I would . . . has he used CB during the last year? You will never get a yes to that.

Before I go on with this, I'd like to just mention this 55 mph speed limit a bit. Unfortunately, most readers are not getting *Car and Driver*. I think that is a great magazine . . . not as great as it was a few years ago, but still great. I can't go into the details they do to show what a farce the whole 55 mph thing is . . . how much lower the accident rate is on the German Autobahns where there is *no* speed limit as compared to our interstates . . . etc. You probably find, as I do, that on the interstates most of the traffic moves along at 65 mph or so. Police, who might do better to follow up on CB reports of drunk or wild drivers, are manning radar speed traps . . . and drivers are countering with more CB and radar detectors.

Car and Driver figures that the next step will be radar jammers. Hmmm. I'm still hoping some enterprising ham will come along with a nice mobile rig for the 10 GHz ham band . . . a tenth Watt will do. That may make the radar people have to put in sharp filters to prevent adjacent band QRM from our rigs. A ham rig like that might sell like crazy.

Letters from ham clubs all around the country confirm that about 80% of the newcomers to amateur radio start out with CB. Wouldn't you, if you were getting going these days? Thus it ill behooves us to sneer at CBers. The chaps who are attracted to CB these days shouldn't be held responsible for the crimes of that bunch of clowns who terrorized the channels a few years ago. Now that the FCC is catching up with licenses and has an instant CB licensing scheme you'll even hear quite a lot of CBers using legitimate calls.

YOU CAN HELP

A few years back I wrote a column for *Electronics Illustrated*. It was a lot of work, but my mail showed that it was accomplishing what I wanted . . . attracting new blood to amateur radio.

In order to get my oar in the main stream . . . and for the same basic reason . . . I am now writing a syndicated CB column for newspapers. The column, called "CB Today," is aimed at educating the CBer and making him aware of amateur radio. I answer the questions CBers have, help them understand about antennas, car noise, the rules and things like that . . . but the end thrust is always to gently encourage them towards an amateur license.

The column has been accepted in 16 cities so far. If you see it in your local paper please send me a copy for my scrap book. If you don't, maybe you could call the editor and suggest that the column would be popular. I'll send samples and other info on it to anyone you suggest. My policy is that the column appear in only one paper in each area, so it is first come first served. If you happen to know the editor personally . . . lean on him.

The papers that are running the column report that it has helped them sell a lot of CB ads. Radio Shack stores in particular jump at the chance. The column is inexpensive and the ad revenue it brings papers pays for the column many times over.

Getting back to *73*. Perhaps you can understand why I was quite enthusiastic about the Standard ad for their Horizon 29 CB rig. I think that any amateur who is not on CB is missing fun . . . missing grand opportunities to talk up amateur radio and get a lot more newcomers to our hobby . . . and certainly is at a disadvantage in driving when he gets no warning of traffic tieups and accidents. Amateurs with FM rigs can report accidents, but they have to go some to beat CBers at this these days. And if you see a drunken driver you aren't going to be in direct touch with a police car unless you have CB. More and more smokeys are wearing ears these days . . . and the results have been good.

Yes, I know some CBers speed . . . so do non-CBers. But since the whole 55 mph thing involved gasoline problems . . . and I see that Detroit is again going more and more into floating boats for our highways which get half the mileage of my little bomb, even if I'm running it at 80 mph . . . perhaps it is time for reason to rule over emotions.

To recap . . . I welcome CB ads in *73* . . . CB is *fun* . . . write for copies of my "CB Today" column for your local paper . . . inventors, we need a radar detector test device . . . mercy me, how about that good buddy?

In case you are still hung up . . . we are getting about four times as many new hams today as a year ago . . . and almost 80% of these are CBers. Can I make it any clearer? Remember back to when you started as an amateur . . . where you met as a friend and buddy or as a lowly, to be sneered at, bum? I've found CBers today to be great people and very enthusiastic amateur newcomers. Extend your hand in friendship and help.

POLITICS AGAIN!

All you President Ford supporters out there should get your letter writing arm oiled up and working, for the White House is again mixing into our rain barrel. The Nixon White House was the big pressure which was pushing for the 220 MHz CB band, for those of you with short memories. Now the Ford White House is hot at it again and 220 is being pushed hard by the Ford group.

A few hundred letters from hams, friends of hams, families of hams, and anyone else you can get to write the Ford we may not like to have in our future can't hurt. If a few hundred letters come in showing Ford that he is losing votes by trying to force the FCC to take away part of a ham band for CB growth, it could have an effect.

Remember, please, that this was the origin of pressure which almost tipped the scales just before Nixon resigned. It would appear that EIA has an incredibly good friend on the White House staff somewhere high up. The FCC, under Chairman Wiley, has been dead set against taking ham frequencies for CB . . . so someone higher up than the FCC had to be bought or convinced.

There is no question that CB *must* have some UHF band if utter chaos (and that's the very best kind of chaos) is to be avoided in a couple of years. Even the White House can't stall off sunspots for much longer. Once those little rascals start burping out ions it will be bedlamsville on CB.

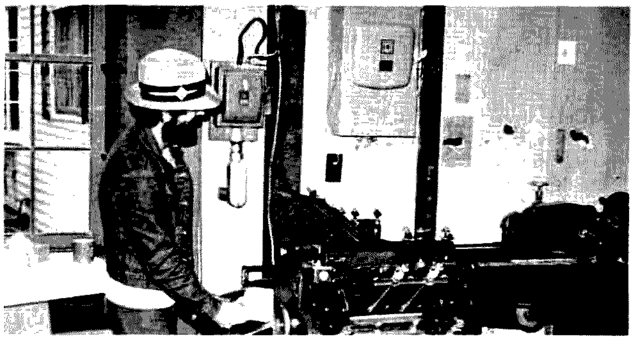
The FCC has been thinking more and more of something nice around 800 MHz. With synthesizers and the new module rf packages, this might be a good idea. It remains to be seen whether the FCC can get moving faster than the White House bunch.

THE SUPPORTING CAST

In response to rather persistent demands that we uncover the anonymity of our fearless crew, we present the first installment of our Kodak renditions of the troops. You asked for it.

Big Bill Edwards WB6BED/1, the ad manager of 73, has been with us for over two years and shows no sign of giving up one of the toughest jobs in the place. Note Bill hard at work. He must be doing something right since 73 has more pages of ads than any other ham magazine.

Meet Dotty Gibson, who has been managing the subscription department for over ten years. If you've called 73 at any time, the chances are you've talked with Dotty and she's helped you with your problem. Dotty is the one who undoes the screwups of our friendly computer down in Massachusetts.



Brent Lawler runs the printing department at 73. The magazine is printed out in Wisconsin, but many of the books are printed in the 73 print shop . . . as are the subscription letters, forms, QSL cards, and things like that. It is enough to keep two men busy full time and then some.

Here is Bob Sawyer, who works in the 73 Magazine art department. Bob lays out most of the QSL card orders and a good many of the nice ads which 73 makes up for manufacturers who do not have advertising agencies.

Here's Judy Waterman, the lovely gal who runs the bulk sales end of things. The office used to be Wayne's a few years back and it was wall papered for his daughter Tully. Some things don't change too fast around the magazine.

Susan Philbrick does the layouts of the articles in 73 whenever she is not taking care of and supporting a bunch of horses and dogs.

I/O REPORT

from page 124

really think we're ignorant!", and "How can you guys stand this?"

Anyway, the other night our hero Steve Austin's mission was to intercept a shipment of sinister *microprocessors*!! As Oscar (his boss) explained it, "If these microprocessors are allowed into the country, they can be used to drain all of our defense computers." Luckily, the country was saved because Austin did get the can (coconut oil can) filled with those crafty, devious little devices and prevented them from falling into the wrong hands. Foreign microprocessors being smuggled into the country in coconut oil cans . . . my gosh, they must have been made on some subversive south sea island!

Miscellaneous

I was cleaning out my desk the other day and came across my old, and yet perfectly good, Post slide rule (in its nice leather case, even). I used to be able to do *everything* with this beauty. I think the fact that it is such a beautiful instrument is what bothered me the most . . . because I just couldn't bring myself to throw it away. I put it back in the desk (in the bottom drawer, way in the back) and I'll probably bring it out some day and show my grandchildren what we used before the hand-held computers came along.

We certainly want to encourage an exchange of ideas (no matter how far out) regarding computer applications in ham radio. So drop me a line if you come up with any . . . and we'll spread the word through the editorial pages or perhaps start a "Letters to the I/O Editor" section. Also, if anyone wants to set up a net to discuss computer applications, hardware, software, etc., send me the frequency and time and we'll be happy to publish them.

We're looking for good articles for the I/O section . . . and writing for *73* can not only be profitable, but quite gratifying. Earn a few extra dollars and at the same time share your ideas and efforts with others. If you have any ideas for articles, drop me a line and we'll talk about them.

LETTERS

from page 10

expensive), but you still need mag tape for data input/output and back up disk dumps. How do we get data printed? Programs loaded/bumped? Sure, some of these units are available to do our I/O, but at present they are 3 times the cost of the CPU and memory. I realize that I/O units are electro-mechanical devices and are expensive to make, but I feel the makers could do much better. Don't you?

Leon Howe WB0LIY
Sashiki-Son, Okinawa

Well, Leon, I just don't see what is wrong with an old (and cheap) Model 15 teletype for hard copy and one of the TVTs for soft copy. I find precious little that I want in hard copy . . . most RTTY contacts via computer and games don't require much of a permanent record. You will be encouraged to know that there are some fairly inexpensive hard copy devices coming, so hold tight — Wayne.

EGO INFLATION

Just a short note of praise to inflate your ego.

Last year with my subscription I got one of your 21+ wpm tapes and decided to go for the Extra when I got the time. I finished medical school two months ago and decided that it would be now or never with the Extra because I would not have the time during my internship. I ordered one of your Extra Class Study Guides and used it in conjunction with the ARRL License Manual and many other references. Your guide was so simple to comprehend that for the first time in my twelve years as a ham I feel I know some of the theory that I had heretofore memorized just for the sake of passing a test.

To make a long story short, I studied daily for one month using your 21+ wpm tape and Study Guide and passed the Extra on the first try last week.

I can't argue with success and sincerely thank the *73* staff for their study materials. Keep up the work.

OUT OF HARM'S WAY

Looks like the hamburglar has a lot of relatives. Business has been on the upswing for the last few weeks, but I am really saddened to say that it has been because of the increased activities of the hamburglar. We now receive calls every day we are open, from hams who have had their equipment stolen from their cars and homes. Today we had three cases, and yesterday two. As you know, I have had many losses myself, the most recent about two weeks ago while in a local restaurant. The police have arrested three suspects with one of the rigs stolen in that break, and although the suspects admitted having the other two rigs, they are out on the streets, will probably not be convicted of the break, and I will probably not have my equipment returned. My insurance agent did not seem too awfully surprised at all this, and it seems to be that the courts are just too busy with larger problems to bother with these cases.
